There are a number of directions for preparing kephir milk, varying more or less in the details. The following is a simple one: About 120 grains of kephir grains are softened by soaking over night in a pint bottle full of water. The following morning the water is poured off and the bottle is three-quarters filled with unboiled milk and tightly stoppered. This is kept at a temperature of 20° C. for from one to three days. The milk is strained through cheese-cloth immediately before use and the residue recovered may be used for fermenting other milk. For various other processes see Kobert (*Zeitsch. f. Krankenpflege*, 1904, p. 377; *Ph. Ztg.*, 1904, 819 and 1912, 277), Drasler (*Med. Klin.*, 1908), and Spivak (*N. Y. M. J.*, 1896). According to Spivak, the changes in milk during kephirization are as follows: 1. Fat, salts, and water remain unchanged; quantity of lactose is lessened and lactic acid is increased. A part of the casein—namely, about 10 per cent.—is transformed into acid albumin and peptone, 10 per cent. into hemialbumose, and the rest loses its lime, and therefore becomes more easily digestible. Alcohol, in amounts of from 0.5 to 1.0 per cent., and carbon dioxide to about 1 per cent. are also produced.

There is largely sold, under the name of kumys, a spurious drink which is made by fermenting sweetened milk with ordinary yeast. It is a pleasant beverage, but differs in important regards from the true kephir milk. The following formula has been suggested by L. Wolff (*A. J. P.*, 1880, 291): "Grape sugar, half an ounce. Dissolve it in four ounces of water. Dissolve twenty grains of compressed yeast, or well-washed and pressed out brewer's yeast, in two ounces of milk. Mix the two solutions in a quart champagne bottle, which is to be filled with good cow's milk to within two inches of the top. Cork well, secure the cork with wire and place in a cellar or ice chest, where a temperature of 10° C. or less can be maintained, and agitate three times a day. In three or four days the koumys is ready for use, and should not be kept longer than four or five days; it should be drawn only with a champagne tap." A beer bottle with patent stopper may be substituted for the champagne bottle.

The composition of true koumys, according to Stalberg, is given below; other analysis may be found in the *J. P. C.*, 1875, 62. *Koumys of June.* In 100 parts, alcohol 1.65, fat 2.05, sugar of milk 2.20, lactic acid 1.15, casein 1.12, salts 0.28, carbonic acid 0.75. *Koumys of September.* Carbonic acid 1.86, alcohol 3.23, fat 1.05, lactic acid 2.92, casein and salts 1.21. These fermented milks vary in composition with the milk they are prepared from. Warnikiewicz found in koumys from cow's milk casein 3.08, butter 2.2, milk sugar 1.77, salts 0.33, lactic acid 0.62, alcohol 1.23 parts per hundred. (See also König's *Nahrungs- und Genussmittel*, 416–419.)

Gordon Sharp (*P. J.*, 1892, 512) stated that the composition of koumys is complex, and that the decomposition which its proteids undergo is closely allied to putrefaction.

Kephir milk is useful either as an accessory or sole food in various conditions of malnutrition. Not only does it offer the nutritive elements of milk in a partially digested form, but it is claimed that the living ferments which are contained in it have an influence in aiding digestion in the alimentary canal, and that it also stimulates the appetite. It first came into Europe as a remedy in *pulmonary tuberculosis*, but has also been recommended in various forms of *dyspepsia*, whether functional or organic, in *anemia*, *rachitis*, and other conditions of impaired nutrition. It has also been employed as an infants' food with asserted remarkable results. Its value in *phthisis* has been extraordinarily lauded by Uroganski. (*Wiener Med. Wochens.*, 1907.)

Keratin.—The outer skin surface, the material of horns, hoofs, tortoise shell, the finger nails, all show a similar chemical composition, the empirical formula of which is said to be $C_{41}H_{71}N_{12}SO_{14}$. The percentage of sulphur varies, however, considerably.

Gissmann boils the quills of feathers in glacial acetic acid for from twenty-four to thirty-six hours in a retort furnished with a return condenser. A thick yellow-brown liquid is thus obtained, which is filtered through glass wool, evaporated on a water bath to the consistence of an extract, and afterwards dried. Dietrich recommends that before the treatment with acetic acid the feathers be digested in water for ten hours and then for eight days macerated in a mixture of equal weights of ether and alcohol, to eliminate fatty matters and cholesterin. The *keratin* obtained by the foregoing process is dissolved with the aid of a gentle heat either in acetic acid or ammonia, and the solution is allowed to clear by standing. Fischer recommends the employment of seven parts of keratin with either one hundred parts of acetic acid, or a mixture of equal parts of ammonia and diluted alcohol. Another method of preparing keratin is by macerating horn shavings, first with a mixture of ether and alcohol, then with a pepsin solution and finally dissolving in glacial acetic acid, filtering and evaporating.

According to Unna and Golodetz (*Monatshefte f. prakt. Dermatol.*, 1907, p. 109), when a horny material is treated with nitric acid, three sorts of keratin may be distinguished. Keratin A, not digested by either pepsin or hydrochloric acid, does not give xanthoproteic reaction; keratin B, not digested by pepsin nor hydrochloric acid but dissolved by nitric acid, gives a xanthoproteic reaction; keratin C, not affected by digestive mixture nor dissolved by nitric acid, gives the xanthoproteic reaction. The various horny substances may contain any one or two of these forms.

Keratin is insoluble in water, alcohol, ether, and diluted acetic acid, or acidulated pepsin solution. Diluted sulphuric acid on boiling changes it into leucin, tyrosin, and other products. It is soluble in concentrated acetic acid, alkalies, and ammonia.

Keratin is used sometimes for the purpose of coating pills, so as to enable them to pass through the acid juices of the stomach unchanged, and be dissolved in the alkaline intestinal fluids. While it has been suggested to protect in this manner the stomach against the effects of irritant drugs, the method is much more frequently used to protect drugs, such as the alkalies, bile-salts, calcium sulphide, pancreatin, tannin, etc., whose activity would be injured by the gastric secretions.

For the preparation of a solution of keratin suitable for the coating of pills several formulas have been proposed in all of which either acetic acid or ammonia is used as a solvent. The acetic solution is suitable for coating pills containing salts of mercury, gold, or iron, arsenic, creosote, salicylic acid, tannin, alum, etc. On the other hand, an ammoniacal solution is preferred for pills containing pancreatin, trypsin, bile-salts, alkalies, iron sulphide, etc. The pill mass must not contain water, for pills will shrink and fissures be produced in the keratin coating. It is, therefore, recommended to use in the making of such pills a mixture of yellow wax, one part, and suet or cacao butter ten parts. It is also necessary to avoid the use of vegetable powders as fillers and to employ in their place kaolin or charcoal powder.

When the pills are ready for coating they should first be dipped in cacao butter and rolled in charcoal powder. To coat with keratin, the pills, placed in a porcelain capsule, are moistened with a suitable quantity of keratin solution and then agitated in the presence of a current of air until the evaporation of the solvent takes place. This moistening and drying require to be repeated many times (sometimes ten) before the layer of keratin is sufficiently thick. The process employed for coating pills with gelatin, which consists in dipping into the solution the pill fixed on the point of a needle, is not suitable here, for it leaves a hole through the keratin coating that can never be completely closed.

In order to insure that the keratin used is insoluble in the stomach, Unna recommends that a preliminary experiment should be made with calcium sulphide pills coated with it. If in the course of some hours after such pills are taken eructations of hydrogen sulphide are observed, it would indicate that the pills have been dissolved in the stomach. Finally, the pills when placed in water should not liquefy or crack. This method of producing what are commonly called *enteric pills* has been largely replaced by the simpler one of hardening a gelatin capsule or gelatin-coated pill by means of formaldehyde solution or vapor, or by coating with salol which gives the same result as regards insolubility in the stomach, but ease of solubility in the intestinal tract. (See *Glutoid*, p. 1411.)

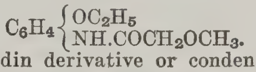
Zypkin (*W. K. W.*, 1907, p. 727) believes that keratin has the property of inhibiting the growth of connective tissue and has used it with asserted benefit in the treatment of various sclerotic diseases, such as *locomotor ataxia* and *cirrhosis of the liver.* He gives from sixty to two hundred and forty grains (3.9–15.5 Gm.) by the mouth, or injects subcutaneously a solution containing 2 Gm. of keratin with 0.1 Gm. of sodium bicarbonate and 10 cc. of water.

Kinkeliba. *Combretum album.* (Fam. *Combretaceæ.*)—The leaf of this plant, growing in Western Africa, is affirmed to be of great value in the treatment of bilious *hematuric malarial fevers.* Heckel and Schlagdenhauffen found in the leaves nothing more active than tannin and potassium nitrate. (See Perrot and Lefevre, *Travaux du Laboratoire de Mat. Méd.*, p. 67.) (See also *Combretum.*)

Kosam Seeds. *Fructus Bruceæ*, Pharm. Nederland.—The seeds of *Brucea sumatrana* Roxb. (Fam. *Simarubaceæ*), indigenous in China and Southern Asia. Schlagdenhauffen found in them a saponin, and Physalis and Bertrand a glucoside, *kosamin.* They are asserted to be useful in *menorrhagia*, also in *dysentery* and *diarrhea.* (*P. J.*, lxiv, p. 463.) According to Power and Salway (*Year-book of Pharmacy*, 1907), the *B. antidysenterica* has similar properties and is largely used in Abyssinia.

Kossala.—An Abyssinian remedy against *tapeworm.* (*Proc. A. Ph. A.*, xxvi.) It is said, however, to produce gastric irritation.

Kryofine. *Cryofine. Methoxyacet-p-phenetidin. Methyl-glycollic Phenetidin.*



$$C_6H_4\begin{cases}OC_2H_5\\NH.COCH_2OCH_3.\end{cases}$$

This phenetidin derivative or condensation product is made by heating paraphenetidin and methylacetic acid together; the acid replaces the acetic acid in the phenetidin derivative and the product is thus closely allied to acetphenetidin. Kryofine crystallizes from aqueous solutions in needles, with a melting point of from 98°–99° C. These crystals are white, at first tasteless, but becoming bitterish when chewed for a few moments. Kryofine is soluble in boiling water 1 in 52, in cold water 1 in 600, soluble also in alcohol, ether, chloroform, and the oils. The physiological action of kryofine has not been worked out, but in a medium-sized dog two hundred and one grains caused general paralysis and extreme slowing of respiration and pulse, ending fatally. Seventy-five grains (5 Gm.) given to man have produced no more serious effect than cyanosis with some lessened frequency of respiration. Kryofine can be detected in the urine from fifteen to twenty minutes after taking, disappearing in from six to eight hours. (Ebstein.) In doses of from two and one-half to twenty-five grains it has been strongly commended as an analgesic for *pains* of purely nervous origin and antipyretic in various *fevers*, as less dangerous, though acting more slowly, than other allied drugs.

The range of action of kryofine appears to be that of acetphenetidin. The assertion that it is less dangerous than that drug seems hardly to be sustained by the facts; depression and cyanosis have been produced by it in various cases. The usual *dose* is eight to fifteen grains (0.5–1.0 Gm.). In the feeble, great caution is necessary in its employment.

Kryogenin. *Meta-benzamino-semicarbazide.* $C_6H_4(CO.NH_2)(NH.NH.CO.NH_2)$.—This is a colorless, odorless, slightly bitter powder, soluble in forty parts of water, more freely in alcohol. It is asserted by Lumière (*Ph. Post*, 1903, 7) to be an antipyretic of value, especially used in *tuberculosis*, producing, it is said, a rapid fall of temperature without unpleasant symptoms. *Dose*, ten to twenty grains (0.6–1.2 Gm.) in capsules.

Labdanum. *Ladanum.*—A resinous substance, obtained from various species of *Cistus* (Fam. *Cistaceæ*), especially *C. creticus* L., *C. ladaniferus* L., *C. cyprius* Lam., and *C. laurifolius* L., small evergreen shrubs, inhabiting the islands of the Grecian Archipelago, and the different countries bordering on the Mediterranean. Upon the leaves and branches of these shrubs a juice exudes, which is collected by means of an instrument resembling a rake, with leather thongs instead of teeth, which is drawn over the plant. The juice adheres to the pieces of leather, and is afterwards separated. It is said that labdanum was formerly collected by combing the beards of goats which had been browsing upon the leaves of the cistus, and Landerer states that it is still gathered in Cyprus from sheep and goats whose fleeces become loaded with it while they are pasturing. (See *P. J.*, xi, 6; xv, 301; xvi, 386, 779.) It comes chiefly from the Grecian Islands. Two varieties exist in commerce. The purest labdanum is in masses of various sizes, sometimes weighing several pounds, enclosed in bladders, dark red, almost black externally, grayish internally when first broken, of the consistence of a plaster, softening in the hand and becoming adhesive, of an agreeable balsamic odor like that of amber, and of a bitter, balsamic, somewhat acrid taste. It is very inflammable, burning with a clear flame. On exposure it becomes dry, porous, and brittle. Little of this variety is found in the markets. Common labdanum is in contorted or spiral pieces, light, porous, blackish-gray, hard and brittle, not softening between the fingers, similar in odor and taste to the preceding variety, but less inflammable, and mixed with sand and other earthy matters, which are obvious to the sight. Guibourt found in 100 parts of the labdanum in masses, 86 parts of resin with a little volatile oil, 7 of wax, 1 of aqueous extract, and 6 of earthy substances and hair. In the contorted variety, Pelletier found 20 per cent. of resin, 3.6 of gum with calcium malate, 0.6 of malic acid, 1.9 of wax, 1.9 of volatile oil, including loss, and 72 of a ferruginous sand. Schimmel & Co. (*Schim. Rep.*, April, 1893) state that they obtained from labdanum resin 0.91 per cent. of a golden-colored essential oil having the penetrating odor of ambergris. Its sp. gr. is 1.011 at 15° C. Labdanum is a stimulant expectorant, formerly given in *catarrh* and *dysentery* and sometimes used in plasters.

Lac. *Lacca. Resina* (*Gummi*) *Lacca. Laque, Gomme lacque*, Fr. *Lack, Gummilack*, G.—A resinous substance obtained from several trees growing in the East Indies, India and Burma, particularly from *Croton laccifera* L. (Fam. *Euphorbiaceæ*); several species of *Ficus*, especially *F. religiosa* L. and *F. indica* L. (Fam. *Moraceæ*), *Schleichera trijuga* Willd. (Fam. *Sapindaceæ*), *Butea frondosa* Roxb., *Acacia arabica* Willd. and *Cajanus indica* Spreng., of the Fam. *Leguminosæ*, and *Zizyphus jujuba* Lam. (Fam. *Rhamnaceæ*). Stillman states that *Acacia Greggii* A. Gray (Fam. *Leguminosæ*) and *Covillea tridentata* (DC.) Vail. (*Larrea mexicana* Moric.) (Fam. *Zygophyllaceæ*), plants growing in Arizona, Colorado, and the Western territories, furnish both *shellac* and *lac dye*. (*A. J. P.*, 1880, 409.) *Lac* is found in the form of a crust, surrounding the twigs or extreme branches, and is generally supposed to be an exudation from the bark, owing to the puncture of an insect belonging to the genus *Coccus*, and denominated *C.* (*Tachardia*) *Lacca* Kerr (Fam. *Coccidæ*). Several varieties are known in commerce. The most common are *stick-lac, seed-lac* and *button lac.*

Many theories have been advanced to account for the formation of this substance, some claiming the resin to be secreted by the insects, others by the plant as a result of an irritation caused by the insects. According to C. S. Misra (*Pharm. Era*, 1919, lii, 95), lac is a secretion produced by a scale insect which sucks the juice of plants. The sap thus taken into the body being greatly transformed and given out uniformly through pores all over the body in the form of resin, which after a few days incases the insect completely. The lac-bearing branches are cut off and placed on trees having a sufficient number of succulent branches. When the young insects have swarmed out the old lac-bearing branches are removed and the resinous incrustation (stick-lac) is scraped off with a knife, ground in a mill, soaked in water and washed. The pure animal resin (seed-lac) thus obtained is mixed with colophony and orpiment, cooked over a slow fire and drawn out into thin sheets, in which form it is commercially known as shellac.

Most of the host plants of the lac insect belong to the *Leguminosæ.* All of these are said by Hassen to contain tannins, gums and substances like hydroxyacids. Tannin is asserted to be essential for the production of gums and so of lac. The lac insect lives upon sweet bacterial gums produced by tissue destroying bacteria.

Stick-lac is the resin as taken from the tree, still encrusting the small twigs around which it originally concreted. It is of a deep reddish-brown color, of a shining fracture, translucent at the edges, inodorous, and of an astringent, slightly bitterish taste. Its external surface is perforated with numerous minute pores, as if made by a needle, and when broken it exhibits many oblong cells, containing the dead insects which contain coloring matter. When chewed it colors the saliva red, and when burnt, diffuses a strong, agreeable odor. It is in great measure soluble in alcohol. It contains as its chief constituents resin, wax and coloring matter.

Seed-lac consists of minute irregular fragments, broken from the twigs and partially exhausted by water. It is of a light or dark brown color, inclining to red or yellow, feebly shining, almost tasteless and capable of imparting to water less color than the stick-lac, sometimes scarcely coloring it at all. It is occasionally mixed with small fragments of the twigs.

Button-lac consists of flat cakes of the resin.

Shellac is a product of *lac.* It is prepared by melting the *stick-lac* or *seed-lac*, previously deprived of its soluble coloring matter, with a small amount of orpiment and resin, straining it, and pouring it upon a flat smooth surface to harden, or pulling it out by hand into large thin orange-colored sheets, which are broken up after cooling.

According to John, lac consists of resin, coloring matter, a peculiar principle insoluble in alcohol, ether, or water, called *laccin*, a little wax, and various saline matters in small proportion. The resin, according to Unverdorben, consists of several distinct resinous principles differing in their solubility in alcohol and ether. The laccin is nearly or quite wanting in shellac, which also contains scarcely any of the coloring principle.

Stick-lac varies in its constituents according to Hassen (*A. J. P.*, 1922, p. 131), depending upon the tree from which it is obtained. When the lac insect is propagated on *Schleichera trijuga*, the product known as *Koosam-lac* is formed. This is claimed to be the richest source of shellac, containing 70 to 80 per cent. of resin. Most of the Koosam-lac comes from the central provinces of Western Bengal. Hatchett found in stick-lac 68 per cent. of resin, and 10 of coloring matter; in seed-lac 88.5 per cent. of resin, and 2.5 of coloring matter; in shellac 90.9 per cent. of resin, and 0.5 of coloring matter. The other constituents, according to this chemist, are wax and gluten, besides foreign matters. R. E. Schmidt (*Ber. d. Chem. Ges.*, 1887, 1285–1303) has prepared the lac dye in a pure crystallized state. He gives it the formula $C_{16}H_{12}O_8$ and calls it *laccaic acid.* It was obtained crystallized from ethereal solution. Caustic alkalies dissolve it, giving a magenta color. Baryta water forms a violet lake. Laccaic acid shows some analogy to carminic acid, but the colors they give on wool and silk are different. Laccaic acid is decomposed on heating with concentrated hydrochloric acid to 180° C., as well as on fusing with caustic potash.

Japanese lac from *Rhus vernicifera* was examined by A. B. Stevens. (See *Proc. A. Ph. A.*, 1905, 311.)

Lac in its crude state is slightly astringent, and was formerly used in medicine, but at present it is not employed. Shellac is wholly inert, unless contaminated with an arsenic compound, which is sometimes used to give it color. It is sometimes used in alcoholic solution as a glaze for confectionery. The use of such insoluble resinous glaze for a food product is prohibited in some states partly on account of its indigestibility *per se* and partly because in its preparation for varnish or pigment purposes arsenical compounds are used to heighten the color and many instances are on record where confectionery which had been coated with such glaze contained appreciable amounts of arsenic. A bleached form of arsenic-free lac has recently appeared in commerce, which would seem to be free from many of the objections previously urged against lac in coating confectionery. Stick-lac and seed-lac are used on account of the coloring principle which they contain. Shellac, as well as the other varieties, deprived of their coloring matter, is applied to numerous purposes in the arts. It is the chief constituent of *sealing wax.* The best red sealing wax is made by melting together, with a very gentle heat, 48 parts of shellac, 19 of Venice turpentine, and 1 of balsam of Peru, and mixing with the melted mass 32 parts of finely powdered cinnabar. But common rosin is often substituted in part for the lac, and a mixture of red lead and chalk for the cinnabar. For methods of detecting adulteration with rosin see *J. Soc. Chem. Ind.*, 24, 1905; also *Chem. Ztg.*, 1910, 991. The best black sealing wax consists of 60 parts of lac, 10 of turpentine, and 30 of levigated bone black; the best yellow sealing wax, of 60 parts of lac, 12 of turpentine, and 24 of lead chromate. (Berzelius.) Lac is also used as a varnish, and forms an excellent cement for broken porcelain and earthenware. It may be dissolved in alcohol, oil of turpentine, benzin, or naphtha. Lac has been highly recommended as an adhesive material for the dressing of *wounds, ulcers*, etc. It is prepared for use by dissolving, with the aid of a gentle heat, in alcohol contained in a bottle, sufficient lac to give it a gelatinous consistence, and then closing the bottle. It is used by spreading it on the bandages. For details of the preparation of shellac, see *U. S. D.*, 19th ed., p. 1543.

Lactagol.—Under this name has been introduced an extract from cotton seed. It occurs as a yellowish-white powder, which emulsifies when rubbed up with water.

Lactagol has been used for the purpose of increasing both the quantity and quality of milk in nursing women. According to Barlerin (*R. T.*, 1906, p. 393), it causes a marked increase in the percentage of fat and also of casein. Abramof (*Cb. G. T.*, 1906, p. 548) noted an increase in the quantity of milk with no change in its composition. Contrary to these experiences, Bruhn (*Ther. Neu.*, June, 1908, p. 161) was unable to notice any decided effect upon the lacteal glands.

Lactanin. *Bismuth Dilacto-monotannate.*—This is a yellow, odorless, tasteless powder, insoluble in water, which has been used in *doses* of three to five grains (0.2–0.32 Gm.) in *tubercular* and other *chronic diarrheas* of young children.

Lactic Acid Therapy.—It is a well known fact that most of the pathogenic bacteria do not grow well in acid medium. The late Professor Metchnikoff conceived the theory that many systemic disorders were due to the absorption of poisons formed by intestinal putrefaction and believed that the freedom of certain Balkan peoples from this group of diseases was due to their habit of drinking fermented milks which produced an acidity in the lower bowel. He attempted, therefore, to implant into the colon a lactic acid forming bacteria. For this purpose he chose the *Bacillus Bulgaricus*, the starter used by the Bulgarians to produce their fermented milk, *yoghurt* (see *Kephir*). This micro-organism is not a normal inhabitant of the intestinal canal and clinical experience has shown that it is very difficult, if not impossible, to produce a growth of it in the intestines. Various other acid forming bacteria have therefore been employed. Among these are the *B. Paralacticus, B. Bifidus* and *B. Acidophilus.* At present the last named is enjoying the greatest favor.

These bacteria are furnished commercially in three forms. (1) In the form of inoculated milk. This should contain, according to the standards of the *N. N. R.* 1924, not less than 50 million viable organisms per cc. It is, theoretically, the most rational form of administration because these bacteria grow best in a milk culture and require lactose in order to produce lactic acid. Bacillus acidophilus milk if properly made (that is, sterilized before implantation) may be stored for a week in a cool place without notable loss of efficacy. The ordinary dose of this milk is from one to three pints per day. (2) In the form of broth cultures. The latter are of two types: those intended for the home manufacture of inoculated milk and those that are intended to be taken as dispensed. These cultures should be marked with an expiration date beyond which they are not to be used and should be stored in a cold place. Most of them are given in doses of from one to three teaspoonfuls. It is advisable that milk sugar be administered simultaneously. (3) In the form of tablets. Although this would manifestly be the most convenient method for administering these bacteria, there is considerable doubt as to how long the lactic acid bacteria retain their viability in the dry state. Certain it is that many of the tablets of this nature contain practically no living organisms. Still another form is the agar jelly chocolate-coated block, each one of which contains as many viable organisms as a pint of acidophilous milk. The disadvantage of these is their instability and their tendency to mould.

On account of their antagonism to tissue-destroying bacteria, lactic-acid bacteria have been suggested and used as application to diseased surfaces and membranes of the body.

Cultures of lactic acid bacteria should be kept cold and used when fresh. Many inert products of this class have been placed on the market, but by shortening the date of expiration and improving the medium in which they are suspended, the manufacturers have largely succeeded in eliminating this defect. Cultures may be tested for activity and relative purity by inoculating sterilized milk and incubating at 37° C. for 24 to 72 hours to determine whether acid is produced without putrefactive odors or taste; strict aseptic precautions should be used throughout.

Lactucarium. *U. S. IX. Lettuce. Lactucarium Anglicum, Lactucarium Germanicum; Strong-scented Lettuce, Green Endive; Laitue virense,* Fr.; *Giftlattichsaft,* G.; *Lactucario,* Sp.—The plants of the genus *Lactuca* of *Compositæ* yield when wounded a milky-juice, to which, indeed, they owe their generic name. Narcotic properties have been attributed to the juice from several species including even the *Lactuca sativa* L., or *garden lettuce,* but only the *L. virosa* L. (strong-scented lettuce) is employed in medicine. This plant, whose dried juice was formerly official, is a biennial, with a stem from two to four feet high, erect, prickly near the base, above smooth and divided into branches. The lower leaves are large, oblong-ovate, undivided, toothed, commonly prickly on the under side of the midrib, sessile, and horizontal; the upper are smaller, clasping, and often lobed; the bracts are cordate and pointed. The flowers are numerous, of a sulphur-yellow color, and disposed in a panicle. The plant is a native of Europe.

It is lactescent, and has a strong disagreeable odor like that of opium, and a bitterish, acrid taste. Under the name of *thridace* the French Codex at one time recognized the expressed juice of the whole plant.

Lactucarium is cultivated in Scotland, Germany, Austria and France. It was officially described as follows: "Usually in quarter sections of hemispherical masses, or in irregular, angular pieces; externally dull reddish- or grayish-brown; fracture tough, waxy; internally light brown or yellowish, somewhat porous; odor distinctive, opium-like; taste bitter. Lactucarium is partly soluble in alcohol and ether and, when triturated with water, it yields a turbid mixture. Treat Lactucarium with boiling water and filter; the filtrate is clear while hot; on cooling it becomes turbid but clears upon the addition of ammonia water or alcohol; it is not colored blue by iodine T.S. (*starch*). An alcoholic solution of Lactucarium gives not more than a faint green color upon the addition of a drop of ferric chloride T.S. (*tannin*). The powder is grayish-brown to dark brown, consisting almost entirely of irregular fragments without any cellular structure: when mounted in hydrated chloral T.S., the fragments become clear, showing granular fragments, and from this deposit, numerous rod-shaped crystals and broad monoclinic prisms as well as aggregates of these, all of which polarize light. In the preparation of powdered Lactucarium, dry the crude drug at a temperature not exceeding 70° C. Lactucarium contains not more than 15 per cent. of moisture, and yields not more than 10 per cent. of ash." *U. S. IX.*

The drug of commerce usually has a growth of mold on the surface. If it has penetrated the drug to any extent it reduces its quality. Occasionally specimens are met with that are moldy throughout, and these should be rejected. In color, taste, and odor, lactucarium bears considerable resemblance to opium; and has been used to adulterate that drug; it is sometimes called *lettuce opium.* It yields nearly half its weight to water, with which it forms a deep-brown infusion. It is partly soluble in ether and alcohol.

From its resemblance in some of its properties and to opium, it was conjectured to contain morphine, or some analogous principle, but this conjecture is false. There is no doubt as to the complexity of the composition of lactucarium, but so feeble are its properties that it has largely gone out of active use, and its chemistry is of little practical importance.

About one-half of lactucarium is made up of a colorless, odorless and tasteless, crystallizable substance—*lactucerin* (*lactucon*). This substance fuses at 210° C., is soluble in ether and hot alcohol, but is not a fat. According to Hesse it is a mixture of the mono-acetyl and di-acetyl esters of *alpha-* and *beta-lactucerol,* $C_{18}H_{30}O$. Various bitter principles have also been described, namely *lactucin, lactucic acid* and *lactucopicrin;* there is, however, considerable uncertainty as to whether these substances are really proximate principles, and there is no evidence that any of them possess therapeutic activities.

The assertion sometimes made that *Lactuca virosa* contains a mydriatic alkaloid has been denied by J. C. Braithwaite and H. E. Stevenson, *P. J.*, 1903, 148. Farr and Wright (*P. J.*, 1904, p. 16) claim, however, to have definitely established the presence of a mydriatic alkaloid, giving alkaloidal reactions with Mayer's and Thresh's reagents, and producing a powerful mydriatic effect upon the eye.

For an examination of *Russian lactucarium,* by L. Schiperovitch, see *Ph. Z. R.*, or *D. C.*, 1886.

Uses.—The ancients believed that lettuce had soporific properties, a superstition which has survived up to modern times probably because of the similarity to opium in appearance and odor. It has been employed in this country to some extent to allay *cough* and quiet *nervous irritation,* but what benefit is derived is probably purely psychical. One of the widely used proprietary preparations of lactucarium of former years owed its activity to morphine, which was later declared upon the label until its use died out.

Dose, ten to twenty grains (0.65–1.3 Gm.), but much larger quantities may be given without obvious effects.

Lactophenin. *Lactyl-p-phenetidin.*

$$C_6H_4\begin{cases}OC_2H_5\\NH.CO.CH.(OH).CH_3.\end{cases}$$

—A white crystalline powder, without odor, having a feeble bitter taste, soluble one part in five hundred of cold water, one in eight and a half parts of alcohol, and having a melting point of from 117.5° to 118° C. It is produced by the action of lactic acid on phenetidin in the presence of dehydrating substances, the lactic acid radical replacing the acetic acid radical of acetphenetidin.

We have very little definite knowledge in regard to the physiological action of lactophenin, but it is improbable that it differs materially in its effects from acetphenetidin. Some assert, however, that it has a somnifacient effect and it is also affirmed to be valuable in *rheumatism*, having specific curative properties inferior to but resembling those of the salicylates.

The statements which have been made that its use is free from danger are, however, not correct. It sometimes produces an exanthematous eruption, which may be macular or diffuse. Wenzel (*Cb. I. M.*, xvii, 1896) reports a case in which after the patient had been taking, for two weeks, fourteen grains of lactophenin a day, there was suddenly developed violent jaundice, with dark brown urine, without fever or slowing of the pulse, with colorless stools. Similar cases had been previously recorded by Franz Rield (*Zeitsch. f. Heilk.*, xvi, 1895). Kronig (*B. K. W.*, 1895) has reported a case of poisoning, with methemoglobin and cyanosis, followed by death. Lactophenin is eliminated, at least in part, by the urine as a paramidophenol.

Lactophenin may be given in *doses* of from five to twenty grains (0.32–1.3 Gm.), repeated in special cases up to a drachm and a half (5.8 Gm.) in a day.

Lakes.—These colors are compounds of vegetable or animal coloring principles with alumina or other metallic oxides, and are usually obtained by adding alum or stannic chloride to the solution of the coloring matter in water, and precipitating by means of an alkali. The alumina or stannic oxide unites with the phenolic bodies in coloring matter at the moment of separation, and forms an insoluble compound, usually of a very bright color. *Lakes* are obtained in this way, from cochineal, madder, Brazil wood, seed-lac, French berries, etc. (See also *Carminum*, Part I.)

Lamium. *Lamium album* Hart. (*L. maculatum* L.) *White Dead Nettle.* (Fam. *Labiatæ.*)—A hairy perennial herb introduced from Europe and found on roadsides and waste places in the United States. Hemostyptic properties were long since attributed by Lusitanus and by Florain to the flowers of this plant, and, according to the more recent researches by Kalabin (*Cb. G. T.*, xx, No. 12), their decoction produces a rise of the arterial pressure due to contraction of the peripheral vessels. The extract was found to cause firm, lasting contraction of the uterus, and the saturated tincture, in *doses* of twenty-five to forty minims (1.6–2.5 cc.) every two or three hours, to be useful in *hemorrhagic metritis* and *metrorrhagia.* Its effects in puerperal hemorrhage were not pronounced.

Lantana. *Lantana brasiliensis* Link. *Yerba Sagrada.* (Fam. *Verbenaceæ.*)—This Brazilian plant contains, according to Negrete, an alkaloid, *lantanine,* which is actively antiperiodic in *doses* of from fifteen to thirty grains (1.0–2.0 Gm.) in the twenty-four hours, given directly after the paroxysm. It is also claimed to be an intestinal antiseptic. (*T. G.*, 1885.) *Lantana camara* L., a small shrub, known in the West Indies as *sage tree* or *wild sage*, contains an alkaloid, *lantanine,* said to resemble quinine in its action.

Lanthanum Nitrate.—*Lanthani Nitras,* $La_2(NO_3)_6.12H_2O$, occurs in large rose-colored prisms which are soluble in water and alcohol. This salt is employed as an antiseptic, preventing the growth of bacteria when used in solutions of the strength of 1 in 2000. (See *Cb. B.*, 1897, xxi.)

Lanthanum Oxide. La_2O_3.—The oxide of lanthanum is an almost white, amorphous compound easily soluble in diluted mineral acids and insoluble in water. It is used as a source of production for other lanthanum salts and technically instead of calcium oxide in oxyhydrogen lights, being, it is said, superior to calcium oxide in many respects.

Lanthanum Oxalate is found in the mixture known officially as *Cerii oxalas* (see Part 1).

Larch Bark. *Laricis Cortex. Br.* 1885. *Ecorce de Mélèze,* Fr. *Lärchenrinde,* G.—The bark of *Larix decidua* Mill. (*Larix europæa* DC.) (Fam. *Pinaceæ*).

The European Larch is a deciduous tree attaining a height of 100 ft. with pyramidal to irregular crown, dark, grayish-brown bark, smooth, yellowish branchlets, soft, compressed, narrow, bright green leaves and purplish pistillate flowers. Its cones are up to 1¼ ins. long and possess nearly orbicular scales. The bark found by Aldridge to contain gum, starch, resin, and tannic acid of the kind which precipitates the salts of iron olive-green. John Stenhouse has obtained from it a peculiar volatile acid, *larixinic acid,* $C_{10}H_{10}O_5$ (*larixine*). For method of separation, see 16th edition, *U. S. D.* Larixinic acid occurs in beautiful white, lustrous crystals, often more than an inch long, of a peculiar somewhat empyreumatic odor, and a slightly bitter and astringent taste, inflammable, volatilizing at 93° C. and melting at 153° C., soluble in 87.88 parts of water at 13.3° C., very soluble in boiling water, soluble in cold but much more so in hot alcohol, and sparingly soluble in ether. It readily crystallizes from its solutions. A very singular and characteristic property is that of forming, when added, in strong solution, in excess, to baryta water, a bulky, transparent, gelatinous precipitate occupying the whole measure of the liquids if concentrated. The inner *larch bark* possesses astringent and gently stimulant properties, and is supposed to have a special tendency to the mucous membranes. It has been found particularly efficacious in *purpura* and other *hemorrhagic affections,* especially *hemoptysis,* and has been given in *bronchitis* with copious expectoration, and in diseases of the urinary passages. It has been used also, mixed with soap and glycerin, as a local remedy in *psoriasis, chronic eczema,* and other cutaneous affections. Of the extract from three to five grains (0.20–0.32 Gm.), of the tincture from thirty minims to a fluidrachm (1.8–3.75 cc.) or more may be given every three or four hours.

Lard Oil. *Oleum Adipis. U. S. VIII. Huile de Graisse,* Fr. *Schmalzöl, Specköl,* G.—"A fixed oil expressed from lard at a low temperature." *U. S. VIII.*

Lard oil is made in large quantities in this country by exposing lard to low temperatures and then subjecting it to very powerful pressure. In this way the stearin of the lard is separated from the olein, the latter oozing out from the presses in the form of a yellowish-white oil, while the stearin is found in the market in hard cakes, and is largely used in making soap. (See *Adeps.*)

Lard oil is "a colorless or pale yellow, oily liquid, having a peculiar odor and a bland taste. Specific gravity: 0.905 to 0.915 at 25° C. At a temperature a little below 10° C., it usually commences to deposit a white, granular fat, and at or near 0° C., it forms a solid white mass. Lard oil is almost insoluble in cold alcohol and only slightly soluble in boiling alcohol; easily soluble in ether, chloroform, benzene, and carbon disulphide. If 5 cc. of the Oil be thoroughly shaken in a test-tube with 5 cc. of an alcoholic solution of silver nitrate (made by dissolving 0.1 Gm. of silver nitrate in 10 cc. of alcohol, and adding 2 drops of nitric acid), and the mixture heated for about five minutes on a water-bath, the Oil should remain nearly or quite colorless, not acquiring a reddish or brown color (absence of more than about 5 per cent. of *cotton seed oil*). The Oil should be completely saponifiable with alcoholic potassium hydroxide T.S. and the resulting soap should be completely soluble in water, without separation of an oily layer (absence of *mineral oils*). If 2 cc. of Lard Oil be mixed in a test-tube with 2 cc. of equal volumes of amyl alcohol and carbon disulphide containing 1 per cent. of sulphur in solution, and the test-tube be immersed to one-third or one-half its depth in boiling salt water, no reddish color should develop in from ten to fifteen minutes (absence of *cotton seed oil* or of *certain other fats*)." *U. S. VIII.* Lard oil should show a saponification value of 195 to 197 and an iodine value between 56 and 74. It is not pure olein, but contains varying proportions of stearin, and is sometimes adulterated with paraffin oil. It was introduced into the U. S. P., 1880, for the purpose of rendering the ointment of mercuric nitrate softer and smoother in consistence, but it was not retained in the process of the U. S. P. IX, mainly owing to the difficulty of obtaining it of sufficient purity in commerce.

Lathyrus. *Lathyrus sativus* L. (Fam. *Leguminosæ.*) *Vetchling. Jarosse, Kasari* (Ind.).—The *White* or *Chickling Vetch*, the seed of which is used in Europe as a food both by man and animals, under the name of "*mutters*," produces, when taken too freely, a condition known as *lathyrismus.* Horses which have been fed on the plant for a considerable period drop while performing the lightest work, in consequence of paralysis of the hind extremities, and in many cases death has followed from bilateral paralysis of the recurrent laryngeal nerves and consequent asphyxia. This laryngeal affection does not occur in the human subject, and death very rarely takes place. In man the muscles of the lower extremities below the knee are apt to be especially affected, the abductors more than the adductors. The muscles of the face, neck, and upper extremities are very rarely, if ever, attacked. The reflexes and the general sensibility are usually not influenced; but Giorgieri has seen the tendon reflexes increased. According to Cantani, the galvanic contractility of the paralyzed muscle is altered, and the transverse markings of the muscles are nearly obliterated by fat globules. In fatal cases the spinal cord has been found normal. Astier obtained from the seeds a poisonous, alkaline, volatile liquid. According to him, this, being volatile, is not present in preparations such as pressed cakes made at a high temperature, which are consequently not poisonous. If, however, such cakes have been prepared at low temperature, they exhibit toxic properties, owing to the retention of the toxic principle. This is in conformity with the experience of the peasants in some parts of Europe, who mix the ground white-vetch seeds with wheat flour, and boil the mixture for food. E. M. Holmes states that these seeds should not be used in foods in any proportions, as they are poisonous. (*P. J.*, 1913, 795.) Stockman (*Ed. M. J.*, 1917, xix, 285) found in the seeds an alkaloid which paralyzed both the central nervous system and the peripheral motor nerves. Dilling (*J. P. Ex. T.*, 1919, xiv, 359) separated two alkaloids both of which appear to paralyze the central nervous system, including brain and spinal cord, and lower the excitability of muscle substance, one being also depressant to the peripheral motor nerves. Betaine and choline have both been reported present.

The *common vetch*, or *tare* (*Vicia sativa* L.), closely related to the above, is a troublesome weed in grain fields. The *V. ervilia*, or *black vetch* has long been known to be toxic; Wilcez and Tschumi (*Schweiz. Ap. Ztg.*, 1919) have reported on its pharmacognosy.

Laurotetanine.—This alkaloid, found in various of the *Lauraceæ* especially *Litsea* species, is said to be a powerful poison, acting like strychnine on the spinal cord. It gives with Froehde's reagent an indigo-blue color, which on the addition of water changes to yellow; with Erdmann's reagent, a transitory bright blue color, becoming brown, and with more nitric acid, it gives immediately a bright red-brown, and with pure nitric acid a dirty brown. It is soluble in excess of alkali. (*P. J.*, vol. xxi, 1891.)

Laurus. *Laurus nobilis* L. *Sweet Bay. Laurier commun,* Fr. *Lorbeer,* G.—The *sweet bay* is an evergreen tree of the Fam. *Lauraceæ*, inhabiting the countries bordering on the Mediterranean. It produces yellow flowers in early spring and later succulent, purple berries. The leaves are alternate, on short petioles, ovate-lanceolate or oblong, entire, pellucid-punctate, of a firm texture, smooth, shining, deep green upon their upper surface, paler beneath. They have a fragrant odor, especially when bruised, and a bitter, aromatic, somewhat astringent taste. They yield by distillation a greenish-yellow volatile oil which contains pinene, phellandrene, cineol, l-linalool, geraniol, eugenol and methyl eugenol; also acetic, isovaleric, and isobutyric acids and esters. The sp. gr. is 0.915–0.930; Opt. Rab. −15° to −22°; ref. ind. 1.4670 to 1.4775; acid number 1 to 3 and ester number 20 to 50. The volatile oil, of which the fruit yields 0.23 per cent., has a sp. gr. 0.88, and is solid at 0° C. (*Schim. Rep.*, April, 1897.) Water distilled from the leaves has their peculiar odor. The berries (*Fructus Lauri*) when dried are black and wrinkled, and contain two oval fatty seeds within a thin, friable envelope; or they may be considered as drupes, with a kernel divisible into two lobes. They have the same aromatic odor and taste as the leaves, but are more pungent. They contain besides a volatile oil, a fixed oil (*Oleum Lauri Expressum*), which, as obtained by expression from the fresh fruit, is of a greenish color, and aromatic odor from retained volatile oil. One of its chief constituents is the glyceryl ester of *lauric acid*, the so-called *laurostearine*, $C_3H_5(C_{12}H_{23}O_2)_3$, which fuses at 45° C. The free acid may be obtained from this by saponification. It cannot be distilled without decomposition. Another constituent of the crude fat is *laurin*, $C_{22}H_{30}O_3$, which can be extracted by alcohol. It forms neutral, easily fusible prisms without odor or taste. Lard, impregnated with the odorous principle of the berries, and colored green by chlorophyll or sometimes by indigo and turmeric, is said to be often substituted for the genuine expressed oil. This may be detected by boiling alcohol, which dissolves the true oil. The leaves, berries, and oil are excitant and narcotic, but are rarely used internally as medicines, and in this country are scarcely employed in any manner. E. M. Holmes, however, states that the berries have been used in Europe to promote miscarriages. (*P. J.*, 1910, 52.) Their chief use is to communicate a pleasant odor to external remedies. The leaves are also used for culinary purposes in communicating their aromatic flavor to soups, stews, etc. They come into commerce frequently as the packing around stick licorice extract from Mediterranean countries.

Lavender Flowers. *Lavandula. U. S.* 1880. *Lavandula vera* DC. (*L. officinalis* Chaix, *L. spica* L.) *Flores lavandulæ*, P. G. *Lavande, Fleurs de Lavande*, Fr. *Lavandelblüthen*, G. *Lavendola*, It. *Espliego Alhucema*, Sp.—Lavender is a small, labiate shrub with sessile, opposite, entire, linear, revolute leaves and terminal spikes of small, fragrant, lavender-colored, bi-labiate flowers. The plant is a native of Mediterranean regions, and covers vast tracts of dry and barren land in Spain, Italy, and the south of France. In England and America it is very largely cultivated. A number of cultural varieties have been produced. The cultivation of lavender has become an important industry and attempts are being made to cultivate the finer qualities of lavender in the United States. For details of lavender culture, see *U. S. D.*, 19th edition, p. 1546.

Lavender flowers have a strong fragrant odor, and an aromatic, warm, bitterish taste. They retain their fragrance long after drying. Alcohol extracts their virtues, and a volatile oil upon which their odor depends rises with that liquid in distillation. Hager obtained from a pound of the fresh flowers from half a drachm to two drachms of the oil. The flowers are frequently sold for packing away with clothing as a moth preventive. Most of the lavender flowers of commerce are obtained from France and England. Lavender is an aromatic stimulant and tonic, but is seldom given in its crude state. The products obtained by its distillation are much used in perfumery, and the volatile oil is official. (See *Oleum Lavandulæ*, Part I.)

Lawsonia. *Lawsonia inermis* L. (Fam. *Lythraceæ.*) *Henna Plant. Mehndi. Egyptian Privet.* —This is a shrub probably indigenous to North Africa and South Asia which is widely cultivated in tropical and sub-tropical countries, especially in Egypt, Persia, India, South Europe, West Indies, Florida and California. It is characterized by spinescent branches, opposite, ovate-lanceolate, entire, pale green leaves with acute apices and attenuated bases, small, 4-merous flowers arranged in panicles of cymes and globose, capsular fruits. The flowers vary from white (var. *alba* Hassk.) to cinnabar-red (var. *miniata* Hassk.) to rose-colored (pure species). Its leaves produce the well-known dye-stuff denominated *henna*, much used throughout the Mohammedan countries of the East. It is probably the substance referred to as *gopher* in the Old Testament. It is largely cultivated in Egypt. The flowers have a strong, pungent odor, and a distilled water prepared from them is used as a cosmetic. The fruit is thought to have emmenagogue properties. The powdered leaves, under the name of *henna* or *alhenna* are used to stain golden yellow the feet and hair of women of the harem. Abd-el-Aziz of Cairo, Egypt, found in it a brown substance, of a resinoid fracture, having the chemical properties which characterize the tannins and therefore named by him *hennotannic acid.* Tommasi (*D. C.*, 1921, lxv, 142) has isolated an oxynaphthoquinone which he claims is the dyeing principle. Henna has been employed both internally and locally, in *jaundice, leprosy*, and affections of the skin.

Most of the so-called henna hair preparations of the market owe their effect to other constituents than henna and a number do not even contain henna as an ingredient.

Lead Arsenate.—This is a white, heavy powder practically insoluble in water. It varies somewhat in composition but is approximately $PbHAsO_4$.

Lead arsenate is not used in medicine but is widely employed as an insecticide application to plants. Cases of chronic poisoning and serious disturbances to health have been ascribed to accidental poisoning from this agent from its use on plants.

Lead Carbonate. *Plumbi Carbonas, N. F. IV. Basic Lead Carbonate; Lead Oxycarbonate; Plumbi Carbonas; White Lead; Plumbum Carbonicum; Carbonas Plumbicus; Carbonate de Plomb, Céruse, Blanc de Plomb, Blanc de Ceruse*, Fr.; *Cerussa*, P. G.; *Bleiweiss*, G.; *Cerussa*, It.; *Albayalde o cerusa*, Sp.—The National Formulary IV recognized, under the title Plumbi Carbonas, "a mixture of lead carbonate and hydroxide [approximately, $(PbCo_3)_2Pb(OH)_2 = 775.32$]." *N. F. IV.*

Normal lead carbonate, $PbCO_3$, occurs in nature as *cerussite.* It may also be prepared by precipitating a solution of lead acetate with ammonium carbonate. It is little used either in the arts or medicine. The salt here referred to, basic lead carbonate, commonly called white lead, is prepared by several methods. By one method it is obtained by passing a stream of carbon dioxide through a solution of lead subacetate. The dioxide combines with the lead hydroxide of the basic salt, and precipitates it as lead carbonate, while a neutral acetate remains in solution. This, by being boiled with a fresh portion of oxide, is again brought to the state of basic salt, when it is treated with carbon dioxide as before. In this way the same portion of acetate repeatedly serves the purpose of being converted into subacetate and of being decomposed by carbon dioxide. The carbonate obtained is washed and dried with a gentle heat. This process, which produces white lead of the first quality, was invented by Thénard, about the year 1802, and is that which is usually pursued in France and Sweden, and known as the "Clichy process."

Another, called the "Dutch process" from its origin in Holland, consists in exposing lead to the vapor of acetic acid, and is the one usually pursued in England and the United States—but in England with some modifications. In this country the lead is cast into thin sheets which are rolled up so as to form cylinders five or six inches in diameter, and seven or eight high, each of which is placed in an earthen pot containing about half a pint of dilute acetic acid, and having within a few inches from the bottom three equidistant projecting knobs in the earthenware, on which the cylinder of lead is supported in order to keep it from contact with the acid. The pots thus prepared are placed side by side, in horizontal layers. The first layer is covered with boards, on which a stratum of tan-bark or of refuse straw from the stables is strewed, and fresh layers of pots, boards, and tan or straw are successively placed until the building is filled. The layers of pots are allowed to remain undisturbed for about six weeks, at the end of which time they are unpacked, and the cylinder of sheet lead in each pot, though still retaining its shape, is found almost entirely converted into a flaky, white, friable substance, which is the white lead. This is separated from the lead yet remaining in the metallic state, ground in mills in the presence of water and finally dried in long shallow reservoirs, heated by steam. Pelouze has succeeded in explaining these processes on one general principle. In Thénard's process it is admitted that the same portion of lead acetate unites with oxide, and gives it up again to carbon dioxide to form the carbonate. In the Dutch process the heat generated by the fermentation of the tan or straw volatilizes the acetic acid, which, with the assistance of the oxygen of the air, forms with the lead a small portion of subacetate. This, by reacting with the carbon dioxide resulting from the decomposition of the tan or straw, or derived from the atmosphere, forms lead carbonate, and is brought to the state of neutral acetate. The neutral acetate returns again to the state of subacetate and, by alternately combining with and yielding up the oxide, causes the whole of the lead to be finally converted into carbonate.

The temperature of the stacks of pots in the Dutch process is about 45° C. If it falls below 35° C., a part of the lead escapes corrosion, and if it rises above 50° C. the product is yellow. The "German" or chamber process differs from the Dutch process only in that the vessels containing the lead are placed in chambers having a perforated floor, through the openings of which the fumes of acetic acid rise acting upon the lead, while carbon dioxide from the burning of coke is passed in and through the chamber. This process is cheaper than the Dutch method, and is said to give an equally satisfactory product. In Carter's process, used in this country extensively, granulated metallic lead is moistened with acetic acid and submitted to the action of carbon dioxide gas in revolving barrels. A number of other methods have been suggested and used to a greater or less extent, but the Dutch process is the one most frequently employed.

The N. F. IV description was as follows: "A heavy, white, opaque powder, or as a pulverulent mass, without odor or taste; permanent in the air. Insoluble in water or alcohol, but dissolved by acetic acid or diluted nitric acid, with effervescence. When strongly heated it turns yellow without charring, and when heated in contact with charcoal it is reduced to metallic lead. Dissolve 2 Gm. of Lead Carbonate in a mixture of 2.5 cc. of nitric acid and 40 cc. of distilled water; not more than 0.01 Gm. of residue remains. Separate portions of this solution yield a black precipitate with hydrogen sulphide T.S.; a yellow precipitate with potassium iodide T.S.; and a white precipitate with diluted sulphuric acid. On completely precipitating 10 cc. of this solution with hydrogen sulphide, the filtrate, on evaporation, leaves not more than 0.01 Gm. of residue. Ignite 1 Gm. of Lead Carbonate in a porcelain crucible; it leaves a residue of lead oxide weighing not less than 0.83 Gm." *N. F. IV.*

It is sometimes adulterated with barium, calcium, and lead sulphates, particularly the first. A mixture of equal parts of white lead and barium sulphate is known as *Venetian white*, while *Hamburg white* is a mixture of 1 part of white lead and 2 parts of barium sulphate, and *Dutch white* of 1 part to 3 of barium sulphate. Louyet has examined samples of French white lead containing considerably more than half their weight of barium sulphate. Barium sulphate, if present, is left undissolved by nitric acid. Chalk or whiting is another adulteration. This may be detected by adding to the nitric solution of the white lead an excess of potassium hydroxide which will redissolve the lead monoxide first thrown down but leave a white precipitate of calcium hydroxide.

Uses.—White lead is largely used in the arts, especially in the preparation of paints. In medicine it has been employed externally as an astringent and protective application to *ulcers, excoriated surfaces, burns*, etc. Its free continued external use has produced lead poisoning and it has been, therefore, largely abandoned for less dangerous agents. Painters, and others whose work brings them in contact with this substance, are frequently victims of chronic lead poisoning (see *Plumbum*, Part I).

Lead Chloride. *Lead Chloride, Horn Lead.*—Lead chloride may be obtained by adding hydrochloric acid to a solution of lead acetate, until completely precipitated, collecting the precipitate on a filter and washing with distilled water. It occurs as a white crystalline powder, soluble in about 140 parts of water, permanent in the air, and with a sweetish, astringent taste. When heated it fuses and cools to a horny, translucent mass (*plumbum corneum*). It is completely soluble in strong hydrochloric acid from which it is precipitated by the addition of water.

The pigments known as *Turner's yellow, Paris* or *Cassel yellow* are mixtures of lead chloride and oxide. They are prepared by heating together the oxide, or carbonate, of lead with the chloride.

Lead chloride was formerly used as an astringent, caustic application to ulcerative epitheliomata, but it has almost completely gone out of use.

Lead Nitrate. *Plumbi Nitras. U. S. VIII. Nitrate of Lead. Nitras (Azotas) Plumbicus. Azotate de Plomb, Nitrate de Plomb*, Fr. Cod. *Salpetersaures Bleioxyd, Bleisalpeter*, G. *Nitrato di piombo*, It. *Nitrato plumbico, Nitrato de Plomo*, Sp. $Pb(NO_3)_2 = 331.12$.—Lead nitrate occurs in "colorless, transparent, octahedral crystals, when obtained by the spontaneous evaporation of cold solutions, or white, nearly opaque crystals, when formed by the cooling of hot solutions; without odor, and having a sweetish, astringent, afterwards metallic, taste; permanent in the air. Soluble in 1.85 parts of water at 25° C., and in 0.75 part of boiling water; almost insoluble in alcohol. When strongly heated, the salt decrepitates, emits nitrous vapors, and finally leaves a residue of lead oxide." *U. S. VIII.* It is largely used in dyeing and calico printing, for the preparation of mordants, and of chrome yellow.

Lead nitrate possesses the astringent and antiseptic properties of the soluble lead salts, but has largely passed out of vogue. It is occasionally applied to excoriated surfaces, and a solution made in the proportion of ten grains to an ounce of water, and colored probably with alkanet, has been used on the continent of Europe as a secret remedy in *sore nipples, chapped hands, cracked lips*, etc. *Ledoyen's disinfecting fluid* is a solution of *lead nitrate* in the proportion of a drachm to an ounce. Moerlonge and Vanzette ascribe remarkable efficiency to lead nitrate in *onychia maligna*, and their statements have been confirmed by other practitioners. It is applied by sprinkling the powder on the surface, and, according to J. Scott, of Belfast, Ireland, a complete cure may be relied on in from fourteen to thirty days.

Dose, one-fourth to one-half grain (0.016–0.032 Gm.).

Lead Oleate. *Diachylon.*—By precipitating a solution of sodium oleate with lead acetate is formed an insoluble lead oleate. It occurs in commerce either in the form of an ointment-like mass or as an unctuous granular powder. It is comparatively little used in this country although it represents the active ingredient in the official ointment of diachylon. (See *Emplastrum Plumbi.*)

Lead Phenolsulphonate. *Lead Sulphocarbolate.* $Pb(C_6H_4OHSO_3)_2 + 5H_2O$.—White, lustrous needles, soluble in water and alcohol and possessing astringent and antiseptic properties. It is used externally in *skin diseases* and *ulcers* instead of, and is stated to be better than, zinc sulphocarbolate.

Lead Saccharate. *Plumbi Saccharas. Saccharate of Lead.—Lead saccharate* is made by saturating a solution of saccharic acid in water with freshly precipitated lead carbonate gradually added. As the acid becomes saturated, the lead saccharate falls in the form of a white powder, being insoluble in cold water, and but very sparingly soluble in that liquid boiling hot. From this E. Hoskins prepared his *lead nitro-saccharate*, by dissolving the saccharate in diluted nitric acid, containing only one part of the acid in twenty parts of the mixture, filtering the solution, and gradually evaporating. The nitro-saccharate is deposited in yellow crystals in the form of regular six-sided plates or prisms. By dissolving one grain of this salt, with five drops of pure saccharic acid, in a fluidounce of distilled water, a solution was obtained which, though slightly acid to test paper, was perfectly bland. This solution was suggested to dissolve urinary *calculi* but is no longer employed in medicine.

Lead Tannate. *Plumbi Tannas.*—This is obtained by precipitating a solution of tannin with one of lead acetate, added drop by drop. It has been used locally in *chronic inflammations* of the *joints, ulcerations, bed sores*, and *sore nipples*, in 20 to 40 per cent. ointments. The preparation here described is a bitannate. Other lead tannates exist.

Lead Thiosulphate. *Lead Hyposulphite.* PbS_2O_3.—When freshly prepared this compound occurs as a white, amorphous powder turning black on exposure to air for some time, due to the formation of lead sulphide. It is soluble in solutions of the alkali thiosulphates and is used in this form in the external treatment of *rhus poisoning*. It is incompatible with acids or acid salts.

Lecin.—This is an elixir of iron albuminate. It is a permanent and non-gelatinizing preparation and asserted to be an extremely assimilable form of iron, containing 20 per cent. albumen and 0.6 per cent. iron.

Lecithin. *Ovolecithin. Phospholutein*, $C_{42}H_{84}NPO_9$, or $C_{44}H_{90}NPO_9$.—*Lecithin* consists of the esters of oleic, stearic, palmitic, or other fatty acid, with glycerophosphoric acid combined with choline; occurring in combination with proteids in many animal and vegetable tissues, especially nerve tissue and the yolks of eggs. The class of lecithins is now known to be widely distributed in both animal and vegetable tissues, although most familiar in its occurrence in the nerve tissues and embryonic cells. It is a yellowish-brown, waxy solid, of a peculiar odor, soluble in an equal volume of cold absolute alcohol and readily soluble in chloroform, ether, and benzine and fixed oils. It is insoluble in water, but swells, and eventually decomposes. It is hygroscopic on exposure in the air and decomposes according to the extent of moisture absorbed. Lecithin is incompatible with alkalies and should be kept in glass-stoppered bottles away from the light.

Lecithin contains 3.8 per cent. of phosphorus. The animal lecithin is *choline di-stearylglycerophosphate*, while the vegetable lecithin seems to be *betaine di-oleylglycerophosphate;* that is, the widely distributed vegetable base, *betaine* (*oxyneurine*), replaces the choline of egg lecithin and the oleic acid radical appears instead of that of stearic acid.

Vegi-lecithin has been studied chemically by C. Gordon Richardson. Besides the replacement of the choline by betaine and the difference in the fatty acids, it differs from *ovi-lecithin* (*vitellin*) in not being precipitated by acetone and being quite insoluble in alcohol, but soluble in all proportions in cold ether. Otherwise, it is readily soluble in all the solvents of ovi-lecithin. It seems to resemble somewhat the *cephaline* of Thudichum, which was obtained from the brain tissue and which is now known as lecithin, and is asserted to be better borne than ovi-lecithin.

Choline is a substance with well marked physiological properties, and is closely allied chemically to the alkaloid *neurine*, a poison of considerable power, which was discovered by Strecker (1849) and has been shown by Brieger (*Ueber Ptomaine*, Berlin, 1895) to occur in decomposing meat. These two substances are very similar in their effects upon the system. They are related physiologically to pilocarpine and muscarine in that they stimulate the peripheral ends of the autonomic nerves. Through this action on the nerve endings they cause an increase in various secretions, especially those of the salivary gland, slowing of the pulse, contractions of the pupil, and an increase in the peristaltic movements of the intestinal and probably other unstriped muscles. Besides these actions, they exercise a depressant influence upon the respiratory center, and in large doses also paralyze the peripheral motor nerves. Choline also lowers the blood pressure by dilating the blood-vessels. When injected into various organs choline produces, according to Hoffman (*W. K. W.*, 1905), destructive changes, similar to those caused by the X-ray. Exner and Sywek (*D. Z. Chir.*, 1906) confirmed these observations, and have had some encouraging results from injection of a 2 per cent. solution of choline in cases of inoperable *cancer*. Reid Hunt (*A. J. Phys.*, 1918, xlv, 231) has investigated the derivative, *acetylcholin* which he finds to be a vasodilator of such extraordinary potency that .000,000,003 milligm. will cause a distinct lowering of blood pressure in the cat.

When taken by the mouth lecithin is partially broken up by the fat-splitting ferments of the pancreas into its constituent parts, but appears also to be in part absorbed unchanged. The absorption of lecithin unchanged seems to be dependent upon the presence of bile in the intestines. The literature upon the effects of lecithin upon the body is enormous in volume and somewhat contradictory in character. In an elaborate review of the evidence published by the Ohio Agricultural Experiment Station (*Bull. No. 5*, March, 1914), Forbes and Keith reached the conclusions that although there is no convincing evidence that lecithin possesses unusual nutritive value in normal animals, in cases of impaired nutrition, especially where there is a condition of depleted phosporus reserve, lecithin encourages phosphorus retention and that while there is some contradiction in the testimony it is probable that lecithin accelerates the passage of food from the stomach and improves digestion in the intestines. Lecithin has been shown by H. C. Wood, Jr. (*U. P. M. B.*, May, 1902) to be non-toxic.

Danilewski found that, in young animals, it caused an increase in the number of red corpuscles, and a gain in weight. Billon (*International Congress of Medicine*, 1904) has confirmed these findings, and also observed a marked increase in the number of white corpuscles. Serono, as a result of studies on human beings, reached the conclusion that the output of nitrogen was increased. Lawrow and Woronzow (*A. I. P. T.*, 1912, xxi, 389), from experiments on the lower animals, reached the conclusion that lecithin had the power of restoring activity to a heart poisoned by various depressants such as chloral, etc. Hanschmidt (*Bio. Chem. Zeit.*, 1913, li, 171) found that the previous injection of lecithin increased the resistance of rabbits to strychnine, chloral and curare but lowered their resistance to ricin.

Lecithin was introduced into medicine with the idea that being a natural compound of phosphorus, it would exercise the tonic effect of this element upon the system without the disadvantages of its toxic action, and there is considerable clinical evidence of its utility in *tuberculosis, neurasthenia, chlorosis, scrofula* and *rickets*. Lancereaux and Paulesco recommend it also in *diabetes*, but Erben (*S. M.*, 1909) observed no benefit from its use in this disease. Although a portion of the lecithin is decomposed in the intestinal tract by the fat-splitting ferments, Slowtzoff asserts that a part of it is absorbed unchanged. Whether or not pure lecithin has any advantage over the yolks of eggs may be questioned. The *dose* of lecithin is from one to three grains (0.065–0.2 Gm.) in pills or emulsion.

There are a large number of proprietary preparations of lecithin on the market. Concerning the liquid forms, attention may be again called to the fact that lecithin is insoluble in water or alcohol, so that any transparent liquid preparation of lecithin must be suspected as containing little of the drug. The following are some of the more popular preparations:

Glyceritum Lecithini. Glycerol of Lecithin.—A 1.6 per cent. of lecithin in pure glycerin. *Dose*, one fluidrachm (4 cc.).

Lecibrin.—A preparation of lecithin from the brain, containing 33⅓ per cent. of lecithin with nucleo-proteins. It is marketed only in the form of gelatin-coated pills, each containing three grains (0.2 Gm.) of *lecibrin.*

Lecipon.—This is stated to contain 10.5 per cent. of lecithin in soluble form.

Lecithan.—A trade name for lecithin.

Lecithcerebrin.—Lecithin prepared from the brain substance.

Lecithmedullan.—A lecithin prepared from bone marrow.

Lecithol.—An emulsion of brain lecithin representing 1.5 per cent. of lecithin. *Dose*, one to two fluidrachms (4–8 cc.).

Neurolecithin.—A trade name for lecithin prepared from the brain and spinal cord of animals. *Dose*, one grain (0.065 Gm.).

Letalbin. (*Lecithin Albuminate.*)—This forms a yellowish, dry, stable powder of characteristic egg yolk taste. It contains 20 per cent. pure lecithin and is adapted as an addition to tablets, pastilles and infant foods.

Ledum. *Ledum palustre* L. (Fam. *Ericaceæ.*) *Crystal Tea. Marsh Tea. Rosmarinus Sylvestris. Marsh Cistus. Wild Rosemary. Lédon, Romarin sauvage*, Fr. *Porsch. Sumpfporsch, Wilder Rosmarin*, G.—A small evergreen shrub indigenous to Arctic regions and found as far south as Newfoundland in North America. It has linear to linear-oblong leaves which are revolute along the margin, dark green above and rusty-tomentose beneath. A variety of this species, *L. palustre dilatatum* Wahlenb., occurs as far south as Maine and is distinguished by its broader leaves which are sometimes glabrous and glaucous on the lower surface. The leaves have a balsamic odor, and an aromatic, camphoraceous, bitter taste, and contain, among other ingredients, volatile oil and tannin. For the properties of the volatile oil, see *J. P. C.*, 4e sér., xx, 244; also *Proc. A. Ph. A.*, xxv, 154. It contains *ledum camphor*, a stearopten, together with valeric and other volatile acids, and *ericinol*, $C_{10}H_{16}O$. The tannin has been named *leditannic acid*, $C_{15}H_{20}O_8$. On boiling with dilute mineral acids it is decomposed, and *ledixanthin*, $C_{30}H_{34}O_{13}$, separates as a yellowish or reddish powder. (Thal, *Ph. Z. R.*, 1883, 268.) Thal also extracted *ericolin*, $C_{34}H_{56}O_{21}$. This is a glucoside, which on heating with diluted sulphuric acid decomposes into sugar and *ericinol*, $C_{10}H_{16}O$, a colorless, peculiar-smelling oil, which turns brown in the air, owing to oxidation. The leaves are thought to be narcotic and diaphoretic, and have been employed in *dysentery* and in various cutaneous affections, particularly *leprosy* and *scabies*. In complaints of the skin they are used both internally and externally, in the form of decoction. In Germany they are sometimes substituted for hops in the preparation of beer.

Ledum grœnlandicum Oeder (*L. latifolium* Ait.) or *Labrador tea*, a larger plant than the preceding, is a native of North America, growing in damp places in Canada and the northern part of the United States. The leaves have an agreeable odor and taste, and were esteemed pectoral and tonic. They are said to have been used as a substitute for tea during the war for independence.

Leek. *Porrum. Porreau*, Fr. *Lauch*, G.—The bulb of *Allium Porrum* L. (Fam. *Liliaceæ.*) The *leek*, which is the national emblem of the Welsh, is a biennial bulbous plant with broad, often keeled leaves and white flowers, growing wild in Switzerland, and cultivated in the gardens of Europe and this country for culinary purposes. All parts of it have an offensive, pungent odor and an acrid taste, dependent on an essential oil, of which allyl sulphide, $(C_3H_5)_2S$, is the main ingredient. The bulb, which is the medicinal portion, consists of concentric layers, like the onion, which it resembles in medicinal properties, though somewhat milder. It is generally stimulant, with a direction to the kidneys. *Dose*, of expressed juice, a fluidrachm (3.75 cc.).

Leonotis. *Leonotis Leonurus* R. Br. (Fam. *Labiatæ.*) *Lion's Ear. Wild Daggar.*—This is a coarse perennial herb of shrubby habit indigenous to South Africa which is said to possess purgative and emmenagogue properties. (See *P. J.*, May, 1885.) The leaves of this plant which are hairy, lanceolate to oblong-lanceolate and serrate, are smoked by the Hottentots like tobacco. It is asserted that in overdose it has a narcotic effect. It is used by the South African aborigines as a cathartic, and in the treatment of *snake bite.* A decoction is also employed externally for various skin eruptions. (*P. J.*, 1907, lxxix.)

Leonurus. *Leonurus Cardiaca* L. (Fam. *Labiatæ.*) *Motherwort. Agripaume, Cardiaire,* Fr. *Herzespann, Wolfstrapp,* G.—An aromatic perennial herb indigenous to Europe but naturalized in North America. An infusion or decoction is sometimes used in *amenorrhea.*

Lepargyræa. *Shepherdia argentea* Nutt. (*Lepargyræa argentea* Greene.) (Fam. *Elæagnaceæ.*) *Buffalo Berry. Bull Berry. Grains de Bœuf,* Fr.—The acidulous fruit of this shrub produced in great profusion in the region of the upper Missouri, is largely used as an article of food. According to Henry Trimble, it contains a little more acid than currants. (*A. J. P.*, Dec., 1888.)

Levisticum. *Levisticum officinale* Koch. (Fam. *Umbelliferæ.*) *Lovage. Radix Levistici,* P. G. *Livèche. Ache de Montagne,* Fr. *Liebstöckel,* G.—This is a tall, perennial, aromatic herb native to South Europe and cultivated extensively in Germany for its rhizome system and fruits. It has bipinnate, cauline leaves with leaflets coarsely toothed at apex and greenish-yellow flowers.

The rhizome is vertical, from 5 to 10 cm. long and 2 to 4 cm. thick with a multiple crown often in longitudinal slices, annulate above and divided below into several subcylindrical flexible branches up to 10 mm. thick; externally yellowish-brown, reddish-brown or dark brown, longitudinally wrinkled; fracture short; texture spongy; inner surface showing a thick bark with numerous radially-arranged oil and resin reservoirs and a yellow porous and radiate wood surrounding a central whitish pith; wood-wedges separated by whitish medullary-rays which also contain oil and resin reservoirs; odor characteristically aromatic; taste aromatic, sweet, pungent and bitter.

The fruits are cremocarps which are ovate-oblong, somewhat flattened, about 4–5 mm. long and yellowish brown. In the drug, these are usually separated into mericarps, each of which shows five primary ribs, the lateral ones being the longest, as well as six vittæ. Both odor and taste are aromatic. Lovage is a stimulant aromatic, and has been employed as a carminative, diaphoretic, and emmenagogue. The best form for administration is that of infusion. The coloring principle has been isolated by M. J. Nicklés, who gives it the name of *ligulin;* it forms red solutions turning blue in the presence of alkalies.

Lewisia. *Lewisia rediviva* Pursh. *Spatlum. Chita. Bitter Root.*—The roots of this fleshy-leaved low perennial of the Fam. *Portulacaceæ,* abundant in the Northwestern United States, were very widely used by the Indians as an article of food. For analysis and description, see *A. J. P.*, 1889.

Liantral. *Lianthral.*—This substance is an extract of coal tar, obtained by treating with benzene, filtering from insoluble residue, and subsequently evaporating the benzene at a temperature not exceeding 80° C. It is a brownish-black viscous fluid which is insoluble in water, freely soluble in benzene, but dissolving only sparingly in fats, ethereal oils, alcohol, ether, acetone, petroleum benzin, and mixtures of these substances. Liantral has been commended by various clinicians as a substitute for coal and wood tars in the treatment of *eczema* and allied skin diseases. It is said to resemble wood tar in its action, but to be more energetic It has been used in ten per cent. solution with olive oil, applied with a brush, or in the form of a dusting powder made by triturating to dryness with the aid of starch, or talc.

Liatris. *L. spicata* (L.) Willd. (*Lacinaria spicata* Hill.) *Spike Gay-feather. Blazing Star. Button Snakeroot.*—An indigenous perennial composite plant growing in meadows and moist grounds from Massachusetts to Southern Ontario and Minnesota, southward. It has a tuberous root, and an erect annual stem, which terminates in a spike of beautiful, purple flower heads, appearing in August. The leaves are all linear. The root is said by Schoepf to have a terebinthinate odor, and a warm bitterish, terebinthinate taste; to be possessed of diuretic properties; and to be useful as a local application in *gonorrhea* and *sore throat.*

The leaves of the allied *Trilisa odoratissima* (Walt.) Cass. (*Liatris odoratissimus* Willd.), or *Vanilla leaf,* are very largely employed in the Southern United States to flavor tobacco, and to preserve clothing, etc., from moths. As a preservative it is worthless. The agreeable odor is due to coumarin, which may be frequently noticed in crystals upon the surface of the smooth spatulate leaves. (*A. J. P.*, Sept., 1881; xlvii, 116; *N. R.*, 1882, 66.) The roots of *L. scariosa* Willd. (*Lacinaria scariosa* Hill) and *L. squarrosa* Willd. (*Lacinaria squarrosa* Hill) (*rattlesnake's master*) have been employed to cure the bite of the rattlesnake. According to Wm. P. C. Barton, all the tuberous-rooted species of *Liatris* are active diuretics.

Libanol.—This is an ethereal oil obtained from the wood of *Cedrus atlantica* Manetti. (Fam. *Pinaceæ.*) It is a yellow liquid of pleasant odor and taste, soluble in alcohol and ether and insoluble in water. In diseases of the respiratory organs it is used as an antiseptic expectorant and also as an inhalation. It is claimed to be a valuable substitute for sandal wood oil in the treatment of *gonorrhea.* It has also been used externally in the form of an ointment in the treatment of *rheumatism. Dose,* fifteen to forty-five minims (0.9–2.8 cc.) several times a day.

Lignol.—This is an oily or tarry substance which is said to be obtained by the dry distillation of a bituminous fossilized wood. Lignol is asserted to be in bactericidal power equal to the 5 per cent. solution of phenol, and is recommended in *eczema, acne, pruritus,* and other chronic skin diseases, and in *doses* of fifteen minims (0.9 cc.) in pulmonary *tuberculosis.* Also, in chronic *irritation of the genito-urinary tract.*

Ligroine. *Ligroïn.*—This name has been applied to a petroleum product which is chiefly used as a solvent. It boils between 100° C. and 120° C. and has a specific gravity varying between 0.707 and 0.722.

Ligusticum. *Lovage.* (Fam. *Umbelliferæ.*)—A genus differing from *Levisticum* (also called Lovage) in having ternately compound leaves and mericarps with 6 to 10 vittæ on the commissural side and 2 to 6 vittæ between each two primary ribs on the dorsal side. The root of *Ligusticum sinense,* under the name of *kao-pên,* is largely used by the Chinese. In the Northwestern United States the large aromatic roots of *Ligusticum filicinum* S. Wats., *Osha Colorado cough-root*, are used to a considerable extent as stimulating expectorants. (See *A. J. P.*, 1890 and 1891.)

Ligustrum. *L. vulgare* L. (Fam. *Oleaceæ.*) *Troène*, Fr. *Rainweide, Hartriegel*, G. *Privet* or *Prim.*—A shrub having numerous varieties which is indigenous to the Levant and widely naturalized and cultivated as a hedge plant. It attains the height of 15 feet and bears opposite, deciduous to semi-evergreen, oblong-ovate, glabrous leaves and dense pyramidal panicles of small white flowers. The leaves, which have an astringent, bitter taste, and the flowers, which are small, snow-white, and of an agreeable odor, have been used in the form of decoction in *sore throat* and *aphthous* and *scorbutic ulceration of the mouth.* The berries are black, have a sweetish bitter taste, and are said to possess purgative properties, and to color the urine brown. They are sometimes used for dyeing. Death in a child between two and three years old is recorded by James Cheese (*P. J.*, 2d ser., viii, 607), as due to the eating of privet berries. The bark was analyzed by M. G. Polex, who found a peculiar substance, which he denominated *ligustrin*, insoluble in ether and absolute alcohol, but soluble in water and diluted alcohol. Strong sulphuric acid gives with *ligustrin* a deep indigo-blue color. Kromayer (*A. Pharm.* (2), cxviii, 19) proved that Polex's ligustrin was only impure *syringin*, $C_{19}H_{28}O_{10} + H_2O$. The large white crystals become anhydrous at 115° C., and fuse at 212° C. Mannite, sugar, muco-saccharine matter, starch, chlorophyll, bitter extractive, bitter resin, tannin, albumen, salts and a crystalline bitter principle, fusing at a little over 100° C., which Kromayer named *ligustron.* Pfau (*A. Pharm.*, 1925, ccxliii, 50) has made a further investigation of the coloring matter of privet berries, which have lately come to be used in Germany in the coloring of wine, and isolated a coloring principle which he obtained in red crystalline needles, and which he named *ligulin.*

Lilium. *Lilium candidum* L. (Fam. *Liliaceæ.*) *Annunciation Lily. Madonna Lily.*—This well-known plant is a native of Southern Europe from Corsica to the Caucasus Mountains and North Persia, but has been long cultivated in gardens. It is considered by many to be the lily mentioned in the Scripture. The plant possesses pure waxy white flowers of delicate fragrance and a subglobular imbricated bulb of white color tinged with pale yellow. The latter is without odor, but has a peculiar, disagreeable, somewhat bitter, and mucilaginous taste. It contains much mucilage, and a small proportion of an acrid principle. In the recent state it is said to have been employed with advantage in *dropsy.* Vomiting, purging, drowsiness, etc., are said to have been produced in a little girl by the pollen of the *tiger lily, L. tigrinum* Andr. (Jeffries Wyman, *Am. J. M. S.*, 1863.)

Limonene.—This terpene, $C_{10}H_{16}$, which is found in many volatile oils, has an odor resembling that of oil of lemon. It has been suggested by Kobert as a substitute for oil of turpentine. Zickgraf (*M. M. W.*, 1910, lvii) has used it with good effects in fetid *bronchitis, bronchiectasis, gangrene of the lung*, and *pulmonary tuberculosis.* He asserts that it is not only much more pleasant to the patient than is oil of turpentine, but is more efficient and less irritant to the kidneys. It may be administered either by inhalation or internally. The *dose* is ten to twenty drops (0.6–1.3 cc.) three times a day.

Linaria. *Linaria vulgaris* Hill. (*Antirrhinum Linaria* L.) (Fam. *Scrophulariaceæ.*) *Common Toadflax, Butter and Eggs. Ramsted. Linaire commune*, Fr. *Leinkraut, Flachskraut, Löwenmaul*, G.—This is a perennial herb whose spreading underground stem gives rise to many slender aerial shoots bearing numerous linear leaves and which terminate in racemes of yellow flowers, each of which shows a spurred, personate corolla with an orange-colored, bearded palate. It is a very common weed in waste places of America, Europe, and Asia. It should be collected when in flower, dried quickly, and kept excluded from the air. When fresh it has a peculiar, heavy, disagreeable odor, which is in a great measure dissipated by drying. The taste is herbaceous, weakly saline, bitter, and slightly acrid. Its constituents are stated to be two glucosides, *linarin* and *pectolinarin* (*P. J.*, lxxix, p. 316), with *linarosnin, linaracrin, antirrhinic*, tannic and citric acid. This plant is said to be diuretic and cathartic, and has been used in *dropsy, jaundice*, and *cutaneous eruptions.* It is most conveniently employed in infusion. The fresh plant is sometimes applied, in the shape of poultice or fomentation, to *hemorrhoids*, and an ointment of the flowers has been employed for the same purpose, and also locally in diseases of the skin. The flowers are used in Germany as a yellow dye.

Linden.—Boussingault calls attention (*J. P. C.*, 4e sér., xv) to a saccharine exudation which occurs upon the leaves of the European *Linden* (*Tilia europœa* L.), which he has found to have the same composition as Tamarisk manna.

Lint. *Linteum Carptum. Charpie*, Fr., G.—The term *lint* is applicable to a substance prepared from linen. It is in fact linen made soft and somewhat fleecy by various mechanical processes, so as to render it suitable for the dressing of wounds. It was formerly made from old linen thoroughly cleansed by washing with soap and water, or by boiling with a weak lye of soda or pearlash. Sometimes, when colored, it was bleached before being washed. Thus prepared, it was operated on by a simple machine, in which the rag, wrapped round a cylinder, was submitted to the interrupted action of a knife made to descend upon it at intervals of one-eighth of an inch, so as to cut the thread in one direction. On being removed from the machine, the cut ends of the thread became untwisted and loose, giving a flossy character to the fabric. To render it smooth, it was passed through rollers, and its ragged edges were trimmed.

In the progress of improvement, machines were invented and patented for manufacturing lint on the large scale. This so-called *patent lint* has almost completely displaced the older kind. It is generally prepared out of cloth manufactured for the purpose, and therefore has whatever advantage may be derived from uniformity of shape and consistence.

Cotton is in several respects inferior to linen for the preparation of lint, and, unless its presence in any manufactured article sold by this name be made known, it should be looked upon as a fraudulent substitution. Its fiber is less soft and therefore more likely to irritate. It has much less absorbing power, and it conveys heat less rapidly. The following are methods by which it may be distinguished (Elsner): (1) A linen thread when held erect, and set on fire, appears, after the flame is extinguished, in a smooth continuous form, while cotton thread similarly treated has a tufted aspect. (2) Under a microscope which magnifies 300 diameters, the linen fiber appears to be a straight nearly solid cylinder, with a slender central canal; the cotton, flattened as a piece of tape, with a wide canal, and often twisted like a corkscrew. (3) The potassium test, proposed by Böttger, consists in exposing the doubtful substance to the action of a boiling concentrated solution of potassium hydroxide. If made of linen, it will in two minutes assume a deep yellow color; if of cotton, it will either remain colorless, or will become very faintly yellow, and if the texture be composed of both, it will exhibit a streaked or mottled aspect. The examination must be quickly made, as the yellow color produced by the potassium becomes faint with time. (4) Sulphuric acid dissolves the linen fiber, while it leaves that of cotton little changed.

Tow, and hemp in the state of *oakum*, have been employed for dressing wounds; but they are only applicable as exterior dressings to absorb the pus, when the discharge of this is very copious. L. A. Sayre prefers picked oakum to lint as more absorbent. (*B. M. S. J.*, lxvii, 84.) *Charpie*, so much used by French surgeons, generally consists of bundles of straight threads, each four or five inches long, made by unravelling old and rather coarse linen.

Linum catharticum L. *Purging Flax.*—Purging flax is an European annual of the Fam. *Linaceæ*, six to eight inches high. The whole plant is very bitter and somewhat acrid, and imparts its virtues to water, which acquires a yellow color. It appears to owe its activity to a peculiar drastic principle, which has received the name of *linin*, and which is afforded most largely by the plant after the flower has fallen. Schroeder (*N. R. Pharm.*, xi, 11) obtained it in lustrous, white, silky crystals, which are neutral in reaction and have a strong persistent bitter taste in alcoholic solution. Purging flax has enjoyed some reputation in Europe as a gentle cathartic, useful in *muscular rheumatism*, *catarrhal affections*, and *dropsy* with disease of the liver. *Dose*, of the extract, from four to eight grains (0.26–0.5 Gm.); of the powder, one drachm (3.9 Gm.).

Lipoiodine. *Di-iodo-brassidinic acid ethyl ester. Ethyl diiodobrassidate—N. N. R.* 1924.—This occurs as white needles, melting at 37° C., readily soluble in alcohol, ether, chloroform and fatty oils, but insoluble in water. Its solution undergoes slow decomposition with the liberation of iodine. It is said to represent 41 per cent. of iodine. Loeb and Velden (*Th. M.*, 1911) assert that this preparation is absorbed unchanged from the intestinal tract, but that after absorption it undergoes slow decomposition, and thereby exercises a continuous iodine effect. Its action is similar to that of calcium iodobehenate (see Part I) and is used as a substitute for the alkaline iodides. It is marketed in the form of tablets, each containing 5 grains (0.3 Gm.), of from five to twenty-five grains (0.32–1.7 Gm.).

Lippia.—A genus of the *Verbenaceæ* comprising about 125 species of herbs and shrubs the majority of which are indigenous to tropical America. Their leaves are mostly opposite or 3-whorled; their flowers small with a 2-lipped, white, rose or purplish corolla, a 2–4 cleft persistent calyx, 4 didynamous stamens and a 2-celled ovary with a single ovule in each cell; their fruits mature as 2 separate nutlets. A number of the species of this genus contain aromatic oils, and several have been used in popular medicine. The *L. citriodora*, H. B. K., yields *verbena oil*, and is commonly known as *Lemon verbena.* From the *L. mexicana*, Podwissotzki (*Proc. A. Ph. A.*, 1886) separated an essential oil somewhat resembling that of fennel, as well as a camphor-like substance which he named *lippiol.* According to Maisch (*A. J. P.*, xlvii, p. 330), however, the plant used by Podwissotzki was probably the *Cedronella mexicana* Benth. Power and Tutin (*A. Pharm.*, 1907, ccxlv, p. 337) found in the *L. scaberrima* (Sonder), a native of South Africa, where it is popularly known as *Beukess boss*, an essential oil somewhat resembling lavender in its odor, a peculiar crystalline substance, which they named *lippianol*, having the qualities of a monohydric alcohol, and a number of other substances not peculiar to the plant.

Liriodendron. *Liriodendron Tulipifera* L. *Tulip Tree. American Tulip-poplar.* (Fam. *Magnoliaceæ.*) *White Tulip.*—The tulip-poplar is a beautiful, stately tree which is abundant in rich soil in the forests from Southern Ontario to Wisconsin and extending into the Southern States, the timber being commonly known as Poplar or White Wood. It is native to Pennsylvania, its fossil vestiges having been found in the Miocene formations within that state. It possesses simple leaves which are truncate and notched at the apex and greenish-yellow cup-shaped flowers marked with orange within at the base. Its formerly official bark was taken for use indiscriminately from the root, trunk, and branches, though that of the root is thought to be the most active. Deprived of the periderm, it is yellowish-white, the bark of the root being somewhat darker than that of the stem or branches. It is very light and brittle, of a feeble, rather disagreeable odor, strongest in the fresh bark, and of a bitter, pungent, and aromatic taste. J. U. Lloyd believes that the active principle is the alkaloid *tulipiferine*, discovered by him in 1886, and this, according to Bartholow, appears to possess toxic properties. (*Ph. Rund.*, 1886, 169.) The virtues of the bark are extracted by water and alcohol, but are injured by long boiling.

Emmett (*A. J. P.*, iii, p. 5) isolated a crystalline compound which he called *liriodendrin.* This was insoluble in water but dissolved by alcohol or ether and did not unite with either acids or alkalies. It had a slightly aromatic odor and a bitter, pungent taste.

Liriodendron is a stimulant tonic, with diaphoretic properties, and has been used in chronic *rheumatism* and *dyspepsia.* Dose, of bark in powder, from half a drachm to two drachms (2.0–7.7 Gm.); of saturated tincture, a fluidrachm (3.75 cc.).

Lithio-mercuric Iodide. $3LiI + HgI_2$.—Under the name of *mercuricide*, a compound iodide of the above formula has been brought out as a germicide. It is soluble without decomposition in water, alcohol and ether, and crystallizes in lemon-yellow crystals which are deliquescent. It is alleged that it is as actively germicidal as corrosive sublimate, but is not corrosive, less poisonous and not precipitable by blood serum, albumins or alkalies.

Mercury and Lithium Iodide, or *Hydrargyrum-Lithium Iodatum* of Merck, is a red and granular crystalline powder of the formula $HgI_2.2LiI$.

It is soluble in alcohol or ether, but wholly incompatible with water, forming a cloudy mixture which soon precipitates mercuric iodide. It has been used in Germany as an antisyphilitic, antilithic alterative, and especially in *gravel* complicated with *syphilis.*

Lithium Acetylsalicylate. *Hydropyrin. Lithiopyrin. Tyllithin.*—This is a hygroscopic soluble substance which, in the presence of moisture, decomposes into lithium salicylate and free acetic acid. It has been introduced as a substitute for acetyl salicylate acid in the treatment of *rheumatism* and *neuralgias.* It is, however, doubtful whether it has any advantage. The *dose* is from eight to fifteen grains (0.5–1 Gm.).

Lithium Agaricinate.—A white powder of a slight saline taste easily soluble in water. It is used as an anhydrotic in the treatment of phthisical *night sweats. Dose,* one and one-half to three grains (0.096–0.21 Gm.).

Lithium Bitartrate. $LiC_4H_5O_6 + H_2O$.—White crystals soluble in water; the resulting solution shows an acid reaction. It is used in the treatment of *gouty conditions* and *suppurative gingivitis.*

Lithium Iodide may be prepared by treating a warm solution of ferrous iodide with lithium carbonate and heating gently to promote complete decomposition. The liquid must be slightly alkaline. It forms a white hygroscopic salt very soluble in water and alcohol. It becomes yellow on exposure to the air due to liberation of iodine. It is used for the same purposes and in the same doses as potassium iodide.

Lithium Quinate. *Urosine.*—This is a mixture of lithium citrate and quinic acid containing 80 per cent. of the latter and 20 per cent. of the former. It is used in *uric acid diathesis* and as an antirheumatic.

Lithospermum. *Lithospermum officinale* L. (Fam. *Boraginaceæ.*) *Common Gromwell. Puccoon. Milium Solis.*—A European perennial, also found along roadsides and pastures of Canada and the Northern United States, the seeds of which are ovate, of a grayish-white or pearl color, shining, rather larger than millet seeds, and of a stony hardness, from which the generic name of the plant originated. They were formerly used as a stimulant diuretic, but are nearly inert.

Lithræa. *Lithræa venenosa* Miers. (Fam. *Anacardiaceæ*).—The leaves of this Chilian plant are said to act upon the skin in a manner similar to *Rhus toxicodendron,* and to contain a resin and an ethereal oil. The tincture of the fresh leaves has been used as a counter-irritant.

Litmus. *Lacmus. Turnsole. Tournesol. Lacca Cœrulea. Lacca Musica. Laquebleu,* Fr. *Lackmus,* G.—Litmus is yielded by some species of lichens from which cudbear is obtained (see *Persio,* Part I). It is prepared chiefly if not exclusively in Holland. The process consists in macerating the coarsely powdered lichens, in wooden vessels under shelter, for several weeks, with occasional agitation, in a mixture of urine, lime and potash or soda. A fermentation ensues, and the mass, becoming first red and ultimately blue, is, after the last change, removed, mixed with calcareous or silicious matter to give it consistence, and with indigo to deepen the color, and then introduced into small molds, where it hardens. It is said that ammonia may be substituted for urine in the manufacture of litmus, but that the reactions necessary for the production of the coloring matter of the litmus are due to the action of the enzyme which is found in the lichens. Litmus occurs in rectangular cakes, from a quarter of an inch to an inch in length, light, friable, finely granular, of an indigo-blue or deep violet color. It has the combined odor of indigo and violets, tinges the saliva a deep blue, and is somewhat pungent and saline to the taste. From most vegetable blues it differs in not being rendered green by alkalies. It is reddened by acids, and restored to its original blue color by alkalies. For a method of purifying commercial litmus by Foerster, see *Nat. Drug.,* 1904, 460.

Its chief use in pharmacy is as an indicator. For this purpose it is employed either in infusion or in the form of litmus paper. The infusion, formerly called *tincture of litmus,* may be made in the proportion of one part of litmus to twenty of distilled water, and two parts of alcohol may be added to preserve it. *Litmus paper* is prepared by first forming a strong clear infusion with one part of litmus to four of water, and dipping slips of white unsized paper into it, or applying it by a brush to one surface only of the paper. The paper should then be carefully dried, and kept in well-stoppered vessels, from which the light is excluded. It should have a uniform blue or slightly purple color, neither very light nor very dark. As a test for alkalies the paper may be stained with an infusion of litmus previously reddened by an acid, care being taken to avoid all excess. By gas light it is said that the change of color cannot be determined by the eye exactly, as the blue of litmus becomes mauve; but this may be obviated by watching the process through a green glass, by which the faintest trace of blue becomes discernible. (*P. J.,* 2d ser., vi, 479.) For the official method of preparing litmus paper, see *Tests, Test Solutions,* etc., Part III.

For chemical constituents of lichens, see *A. J. P.,* 1898, 455.

Loco Plants. *Crazy Weeds.*—These are plants of the Fam. *Leguminosæ* growing in the plains regions of far Western States, the eating of which by horses and cattle is believed to produce loss of flesh, disordered vision, delirium, convulsive movements, or stupor and death. The chief loco plants are *Astragallus Lamberti* Pursh. (*Oxytropis Lambertii* Greene), commonly known as *rattle weed* or *white loco,* extending from Alberta and Assiniboia in Canada south into Mexico and from Minnesota and Kansas to the Rocky Mountains, and *Astragalus mollissimus* Torr., the *purple loco, woolly loco* or *Texas loco* which ranges from South Dakota south to Mexico and through Western Nebraska, Kansas, Oklahoma, Texas, New Mexico, Eastern Arizona, Colorado and Southwestern Wyoming. There are quite a number of other plants causing heavy losses to stock men of the West.

Isaac Ott found a plant, which he believed to be *A. mollissimus,* to act as a violent spinal poison and mydriatic (*N. R.,* Aug., 1882), and, according to Carl Ruedi, the decoction produces in the rabbit great hilarity, excitement, and even ferocity, and contains an alkaloid, *locoine,* and an acid. (*Tr. Col. State Med. Soc.,* 1895.) On the other hand, O'Brien, of the State Agricultural College of Colorado, was not able to obtain any active chemical substance from six U. S. species of the genus, including the two previously mentioned, while in a very careful study of a plant which was neither in flower nor in seed, but whose identification as *A. mollissimus* was clear, H. C. Wood found that it was not poisonous to rabbits or dogs, a result which has been confirmed by Ingersoll (*Proc. A. Ph. A.*, 1890) and O'Brien (*Bulletin 25, Agricultural Experiment Station of Colorado*) and others. It would appear that *A. mollissimus* is not a poisonous plant. Other species of the genus, especially *A. Hornii* A. Gray, *A. Bigelovii* A. Gray, and *A. caryocarpus* Ker., Gawl, have had poisonous properties attributed to them, and in the fruit of the last-mentioned species G. B. Frankforter believes he has demonstrated the presence of an alkaloid. In 1908 Crawford brought forward the interesting theory that the poisonous effects of the *loco weed* were due to barium, but Alsberg and Black (*Bull. 246, U. S. Bureau of Plant Industry*, 1912) have shown that many other plants in the same localities contain equal quantities of barium, but do not produce the characteristic symptoms, and that the barium is in such an insoluble form as to render improbable that it would be absorbed in the intestinal tract. There can be no doubt that domestic animals are destroyed in the West in very large numbers from an affection which is known as "loco," and hundreds of thousands of dollars have been spent in bounties by the State of Colorado for the extirpation of the supposed poisonous astragalus. It is probable that many of the deaths attributed to loco have been from other causes. Thus, Ingersoll of the Colorado State Agricultural College, found in a large number of locoed sheep masses of *Tœnia expansa*, which he believed to be the cause of death. It is a probable explanation that the phenomena of loco disease are due to the fermentation of an astragalus or other plant in the intestines of the animals, and the production of one or more poisons which are absorbed and produce narcotic symptoms. If this be correct the loco disease is parallel in its etiology and nature to the lathyrismus of Europe. See *Lathyrus sativus;* also *N. Y. M. J.*, 1889, xlix. Similar effects are produced in horses by the pods of the mesquite (*Prosopis juliflora* DC.), when eaten too freely.

According to Haeckel (*Die naturlichen Pflanzen Familien*), the Russian grass *Stipa capillata* L. frequently kills sheep, not, however, by a direct poisonous action, but by its glumes working through the skin into the vital organs; and *Stipa Vaseyi*, which is said in some parts of New Mexico and Texas to be known by the name of "*sleepy grass*," is believed by some ranchers to be the cause of loco disease. Lescohier (*M. R.*, 1911, xx, p. 273) finds that the sleepy grass is an active respiratory poison, and also has some depressant action upon the heart muscle. He suggests that the apparent narcosis produced by the injection of it into the lower animals, is due to partial asphyxiation. This explanation, however, seems improbable in light of the symptoms which are reported in animals which have eaten the grass. Gillespie (*B. M. J.*, 1908, ii, p. 1059) reports that the drug is not only a narcotic, but also a diuretic and sudorific.

Lodal. (6: 7-dimethoxy-2-methyl-3: 4-dihydroisoquinolinium chloride.)—Under this name has been introduced a derivative of papaverine. It has been studied by Laidlaw (*Biochem. J.*, 1910, v, 243) who finds that it resembles hydrastinine in its physiological action, causing a rise in the blood pressure through a direct stimulating influence on the muscles of the heart and arteries. This stimulant influence on involuntary muscle is also shown most markedly in its effect upon the uterus in which it causes tonic contractions. It has been brought forward as a remedy for *menorrhagia* and *dysmenorrhea.* It is marketed in the form of tablets each containing one grain (0.065 Gm.).

Lolium. *Lolium temulentum* L. *Darnel. Bearded Darnel. Ivraie*, Fr. *Lolch, Taumelkorn*, G. —This grass, thought to be the "*tares*" of the Scripture, has spread over the world wherever wheat is cultivated, but is rarely found in the United States. It owes its importance to its growing especially with wheat, so that its ground seeds are eaten in the flour. From ancient times its seeds have been believed to produce an intoxication similar to that of alcohol; hence its specific Latin name and the French name, *Ivraie.* In the sweetish seeds, P. Antze (*A. J. P.*, 1891, 568) believed that he found a solid alkaloid, *temulentine*, and a volatile one, *loliine;* but Hofmeister (*A. J. P.*, 1892, 611) determined that the volatile alkaloid was an impure ammonia, while the temulentine was a mixture which contained a nitrogenous acid and an uncrystallizable alkaloid, *temuline*, of which the hydrochloride has the formula $C_7H_{12}ON_2.2HCl$.

It is alleged that *lolium* seeds produce vertigo, dizziness, headache, somnolence, and general intoxication in man, as well as in dogs, sheep and horses, while they are innocuous to hogs, cows, and poultry. Rivière and Maizière (*J. P. C.*, 1863, 280) have recorded death as occurring from the use of bread containing large amounts of darnel. P. Antze found that both *loliine* and *temulentine* are poisonous, causing violent gastro-intestinal irritation, dyspnea, and general depression. (*Cb. G. T.*, 1891.) M. P. Guerin believes the poisonous properties of darnel are due to the presence of a fungus. (*Morots Journ. de Bot.*, 1898.)

Lonchocarpus. *Lonchocarpus violaceus* (Jacq.) H. B. K. *Stinkwood.* (Fam. *Leguminosœ.*)—The wood of this papilionaceous tree is said to be used by the natives of Surinam as a fish poison. (*Ph. Cb.*, xxxix, 282.)

Lonicera. *Lonicera Caprifolium* L. *Honeysuckle.* "*American*" or *Italian Woodbine.* (Fam. *Caprifoliaceœ.*)—The flowers of this climbing honeysuckle are sometimes used in perfumery, and a syrup of the fruit has been commended in *asthma.* The fruit of all the species of *Lonicera* is said to be emetic and cathartic (Mérat and De Lens), and that of *L. xylosteum* L. to have caused serious poisoning. (*J. P. C.*, 4e sér., xviii, 65.)

Loretin. *Meta-iodo-ortho-oxyquinoline-ana-sulphonic Acid.* $C_9H_4IN.OH.SO_3H$.—This organic iodine compound, discovered by Claus of Freiburg, contains 36.2 per cent. of iodine and is a bright yellow, odorless, crystalline powder, insoluble in ether and oils, soluble in 500 to 1000 parts of cold water, and in 167 to 200 parts of boiling water; it forms neutral soluble salts with sodium, potassium, ammonium, and magnesium, yielding deep orange-yellow solutions. It is very stable for an iodine compound, not being affected by exposure to direct sunlight. It was found by Ammelburg to be much more powerful as a germicide than iodoform, with seven different pathogenetic germs essayed. Given hypodermically to guinea-pigs (5 cc. of a 5 per cent. solution for long periods), it produced no poisoning, and no iodine could be detected in the urine. (*Deutsche Zeitsch. für Thier. Med. und Vergleich. Path.*, 1894.)

It has been especially commended as a substitute for iodoform by Schinsinger and by Snow. (*B. M. J.*, 1891, ii.) It may be used as a dusting powder alone or mixed with calcined magnesia or starch; as collodion, from 2 to 10 per cent.; as ointment, 5 to 10 per cent.; and in solution, 1 to 2 per cent. of the soluble sodium salt. The soluble calcium salt, *calcium loretin*, has been especially recommended for the manufacture of antiseptic gauze. Snow states that the pure powder may be used without danger of poisoning or of local irritation.

A substance closely allied to loretin is known as *tryen* or *yatren*. Anselmino (*Ap. Ztg.*, 1914) believes that it is chemically identical with loretin, although there has been some difference of opinion on this point. According to Herzberg (*B. K. W.*, 1922, i, 1830) it is ortho-oxy-iodo-sulphonbenzol-pyridin. Tryen appears to be an active germicide and has been used by Blun (*D. M. W.*, 1913) and others in the treatment of *gonorrheal infections*, and by Bischoff (*D. M. W.*, 1913) as an insufflation in *diphtheria*. Pfeiler (*B. K. W.*, 1921, lviii, 1413) has obtained remarkable results from the intravenous injection of yatren in *actinomycosis* of cattle and suggest its use in human beings both in this condition and in the allied condition known as *Madura foot.* Muhlens and Menk (*M. M. W.*, 1921, lxviii, 802) report very favorable results from the use of yatren in amebic *dysentery*. They used rectal injections of 200 cc. (6 fluidounces) of a 5 per cent. solution or 1 Gm. (16 grains) by mouth three times a day. Zieler (*M. M. W.*, 1922, lxix, 664) has reported two cases with symptoms of acute yellow atrophy of the liver from intravenous use of yatren after several doses of 0.2 to 0.5 Gm. at intervals of one or two days.

An isomer of loretin has also been advanced under the name of *lorenit*, and is used for the same purposes as loretin. It is *para-iodo-ana-oxyquinoline orthosulfonic acid.*

Under the trade name of *griserin* the *sodium loretinate* has been introduced for the purpose of combating various systemic infections, as *tuberculosis, typhoid fever*, etc. It has, however, been violently condemned by a number of authors as not beneficial, but even actually harmful.

Bismuth loretinate is used as a surgical dusting powder, also internally in *tuberculosis enteritis* in doses of eight grains (0.5 Gm.) several times a day.

Lotus. *Lotus arabicus* L.—According to W. R. Dunstan and T. A. Henry, the leaves of this leguminous plant contain a yellow crystalline glucoside, *lotusin*, $C_{22}H_{19}NO_{10}$, and an enzyme, *lotase*, by which lotusin is converted into prussic acid and a yellow substance, *lotoflavin*. (*Proc. Roy. Soc.*, lxvii, 224.)

Luargol.—This is said to be an arsenobenzol reinforced with silver and antimony. Dalimier and Levy-Frankel (*P. J.*, 1916, xcvi) report successful results from it in the treatment of *syphilis;* they state that it causes an extraordinary rapid disappearance of the visible lesions of the infection such as gummata and skin eruptions although they have not investigated the final results. They claim it has the advantage over arsphenamin in that its solutions are relatively stable remaining unaltered for several hours. They also have found it useful in cases of *psoriasis*. They injected 0.1 Gm. (one and one-half grains) and upwards at a dose.

Disodo-Luargol is a new form of luargol freely soluble in water, giving a brown solution. The beginning dose is 0.05 Gm. gradually increased to 0.3 Gm. (one to five grains). (*Ph. Era*, 1918, li, 51.)

Luatol.—In 1921 Sazerac and Levaditi (*A. In. Past.*, 1922, xxxvi, 1) showed that certain bismuth compounds possessed a spirocheticidal power. They reached the conclusion that the most useful of these from a practical standpoint was *sodium and potassium tartro-bismuthate.* Under the name of *Luatol* has been introduced a 10 per cent. aqueous solution of this salt. This preparation is sold in the United States under the trade name of *bismosol*. *Trepol* is an oily suspension of the same substance.

While at the present writing there is not sufficient data to make an accurate judgment of the value of the bismuth compounds in *syphilis*, there is considerable evidence of their curative effect. Although, as far as we know, no serious poisonings in human beings had been reported, it should be remembered that the doses employed are certainly capable of toxic effects, the most important being stomatitis, the early symptoms of which are a foul breath, blue line on the gums and salivation. Lucke and Klauder (*J. P. Ex. T.*, 1923, xxi, 313) have shown that bismuth has a predilection for the kidneys and may give rise to serious nephritis. The *dose* of sodium and potassium tartro-bismuthate is about one and one-half grains (0.1 Gm.) injected intramuscularly every other day for one or two months.

Another form of bismuth which has been brought forward as an antisyphilitic is the *bismuth salicylate.* This is marketed in ampules, each containing two grains of the salt suspended in olive oil. The contents of one ampule may be injected intramuscularly twice a week (Ballenger and Elder, *T. G.*, March 15, 1925).

Luffa. *Luffa cylindrica* (L.) Röm. *Vegetable Sponge. Wash-rag Sponge. Gourd Towel.*—A cucurbitaceous plant, indigenous to Arabia and Egypt, furnishing a gourd fruit, which presents upon the removal of the epidermis a durable skeleton of interwoven woody fibers, which are used in place of sponge. For description of this plant see Weber. (*A. J. P.*, 1884, 6.) The fruit of *L. echinata* Roxb., of India, is a violent irritant poison, from which C. J. H. Warden has separated a principle allied to, if not identical with, *colocynthitin.* (*P. J.*, June, 1890.)

Lupinus. *Lupinus albus* L. *White Lupine. Lupin*, Fr. *Feigbohne, Wolfsbohne*, G.—A plant belonging to the *Leguminosæ*, and a native of Europe and Western Asia, which is sometimes cultivated in our gardens. Other species are also met with —*L. hirsutus* L., *L. luteus* L., *L. polyphyllus* Lindl., *L. densiflorus* Benth. The last two are indigenous to the Pacific slope and the West. The bitter principle *lupinin*, $C_{29}H_{32}O_{16}$, is a glucoside, and its solution in alkalies is of a dark brownish-yellow color. On boiling with dilute acids it is decomposed into *lupigenin*, $C_{17}H_{12}O_6$, and a fermentable, dextro-rotatory glucose. The bruised seeds of white lupin, after soaking in water, are sometimes used as an external application to *ulcers*, etc., and internally are said to be anthelmintic, diuretic, and emmenagogue. An instance has been recorded where a decoction used as an injection in the rectum caused symptoms which suggested a poisonous character for the drug. Schmidt (*A. Pharm.*, 1897, ccxxxv) has found an alkaloid, *lupanine*, $C_{15}H_{24}ON_2$, in *L. angustifolium*. *Hydroxylupanine*, $C_{15}H_{24}O_2N_2$, is also stated to be present. It is a pale, yellow, syrupy fluid of an intensely bitter taste and showing a green fluorescence. Two alkaloids, *lupinine*, $C_{10}H_{19}ON$, and *lupinidine*, $C_8H_{15}O_2N$, have been isolated from the seeds of *Lupinus luteus* and *L. niger*, the former a crystalline powder and the latter a syrupy liquid. According to Willstätter and Marx (*B. Chem. G.*, 1904, xxxvii) lupinidine is identical with sparteine. For study of the constitution of lupinine see Willstätter and Fourneau (*B. Chem. G.*, 1902, xxxv, 1914). Steiger (*J. Soc. Chem. Ind.*, 1886, 385) has also studied a carbohydrate analogous to dextrin, which Baeyer and Eichborn discovered in *Lupinus luteus*. He finds that it is not changed by yeast, that nitric acid converts it into mucic acid, and that diluted sulphuric or hydrochloric acid converts it into galactose.

According to Schwartz (*W. K. R.*, 1906) the seeds of the *Lupinus arabicus* contain *calcium-anhydro-oxydiamine phosphate*, to which he has given the name of *magolan* and which is a useful remedy in *diabetes mellitus*. It occurs in crystals which yield a green precipitate with copper acetate. The *dose* of magolan is three grains (0.2 Gm.) several times daily.

Lycetol. *Dimethylpiperazine Tartrate.* $NH(CH_2CHCH_3)_2NH + H_2C_4H_4O_6$.—This is the tartrate of a substitution product from piperazine, in which an atom of hydrogen in each of two CH_2 groups is replaced by the methyl group CH_3. *Lycetol* is a white powder melting at 250° C., readily soluble in water, having a taste which is described as pleasant and acidulous. Alkalies react on it, liberating from it the insoluble free base, and while anhydrous it is stated to be slightly hygroscopic. It is asserted that it is an active diuretic, exerting a powerful solvent influence upon uric acid, and causing no disturbance of digestion even when given continually in large doses. According to Hamonic, it acts very favorably in purulent *cystitis*, lessening suppuration and the tendency to decomposition of the urine. It has been used with asserted excellent results in *chronic* and *acute gout*, and in various other forms of *uric acid diathesis*, as well as for solution of *calculi*. *Dose*, of lycetol, from fifteen to thirty grains (1.0–2.0 Gm.) daily, administered in from one to two pints of water.

Lycium. *Matrimony Vine.* (Fam. *Solanaceæ.*) —Different species of *Lycium* have been used in various parts of the world for supposed medicinal virtues. *L. vulgare* Dun. (*L. halimifolium* Mill.), indigenous in the south of Europe and in Asia, is a thorny shrub, with long flexible branches, and is cultivated for hedges and arbors. Husemann and Marmé found in the leaves and stem an alkaloid, *lycine*, $C_5H_{11}O_2N$. (*A. J. P.*, 1864, 226.) Husemann believes that lycine does not exist in the plant, but is formed during the process of extraction, and also that it is identical with *betaine*, $C_5H_{11}NO_2$, the alkaloid obtained from beet juice by Scheibler, and with the oxyneurine of Liebreich (*A. J. P.*, xlvii, 209.) E. Schmidt found in *Lycium vulgare* traces of mydriatic alkaloids, resembling those of belladonna. (*Ap. Ztg.*, 1890, 511.) White, however, (*B. Sc. Pharm.*, 1921, xxviii, 503) failed to find any evidence of a mydriatic alkaloid. The young shoots of one of the species of *Lycium* are eaten in Spain as asparagus, and its leaves as salad, and the aborigines of Colombia used another species against *erysipelas*. The leaves of *L. vulgare*, as well as the fruit, are said to be used by the physicians of Japan.

Lycopodium Saururus Lam. *Piligan.*—In this Brazilian lycopod Adrian has found an actively poisonous alkaloid, *piliganine*. (*C. R. A. S.*, June, 1886; see also *B. G. T.*, cxi, 174.) Piligan is stated to contain also a resin which is mildly purgative. It has been used as an emeto-cathartic.

Other species of *Lycopodium*, as *L. selago* Dill. and *L. polytrichoides* of the Sandwich Islands, have been used as cathartics.

Lycopus. *U. S.* 1870. *Lycopus virginicus* L. *Lycope de Virginie*, Fr. *Virginischer Wolfsfuss*, G.—The *bugle-weed* is a labiate which grows throughout the greater part of the Eastern United States. The whole herb is used. Jos. L. Weil found 0.41 per cent. of fat melting at 50° C., 0.68 per cent. of a granular wax melting at 70° C., 0.43 per cent. of a crystallizable resin soluble in ether, a crystallizable glucoside, and a small quantity of gallic acid and tannin. (*A. J. P.*, 1890, 72.) It has a peculiar odor and a nauseous slightly bitter taste, which it imparts to boiling water.

Lycopus europœus L., a native of Europe, growing in waste places from Massachusetts to Virginia, is said to be frequently collected and sold for *L. virginicus*. The former may be distinguished by its acutely quadrangular stem, its narrow lanceolate leaves, of which the lower are somewhat pinnatifid, its more crowded flowers, and the acute segments of its calyx, armed with short spines. It has been employed in Europe as a substitute for quinine.

According to A. W. Ives, the bugle-weed is a mild narcotic and an astringent, useful in pulmonic and other *hemorrhages*. *Dose* of decoction (one ounce to one pint of boiling water), from one to four fluidounces (30–120 cc.).

Lycoris. *Lycoris radiata* Herb. (Fam. *Amaryllidaceæ.*)—According to Morishima (*A. E. P. P.*, 1897, xl, 121), this bulbous plant contains two alkaloids, *lycorine*, $C_{16}H_{17}O_4N$, which occurs in large colorless polyhedric crystals, and is physiologically active, resembling emetine in its action, and *sekisanine*, $C_{34}H_{36}O_9N_2$, which occurs in colorless, anhydrous columns and is quite inactive physiologically. More recent investigations indicate that lycorine is identical with narcissine (see *Narcissus*).

Lygosine. *Sodium Lygosinate.*—This is the sodium Salt of Diorthocumarketone. $CO(CH{:}CH.C_6H_4.ONa)_2 + 7H_2O$. It occurs as shining, metallic, green crystals, forming a red solution in water. According to Aujezki, it is feebly bactericidal, also capable of lowering the temperature in fevered rabbits. It has been used by Stray (*D. M. Zeit.*, 1909, No. 7) successfully in the treatment of *gonorrhea*, especially in women. For this purpose it is employed in solutions containing from one to five per cent.

Quinine lygosinate is a vivid orange-yellow color, representing approximately 70 per cent. of quinine. It is odorless and almost insoluble in water, but soluble in alcohol. Filep asserts that quinine lygosinate is actively bactericidal, and it has been employed clinically by Fürth (*Pharmakologische und Therapeutische Rundschau*, 1905, No. 12, p. 89) as a dusting powder in *old ulcers*, and for other surgical purposes. It is also claimed for the substance that it possesses styptic properties.

Lysidin. *Ethylen-ethenyl-diamine Hydrochloride. Methyl-glyoxalidin.* $C_4H_8N_2HCl$.—The article sold as *lysidin* is a 50 per cent. solution of the base *methyl glyoxalidin* which is chemically related to piperazine. The true base forms small colorless, extremely hygroscopic crystals, very soluble in water with an alkaline reaction, and giving the usual alkaloidal reactions. It is incompatible with acids and the salts of many metals and of the alkaloids. It is employed in the *uric acid diathesis,* thirty to one hundred and fifty grains (2–10 Gm.) being administered daily. The bitartrate forms the most stable salt. (*P. J.*, 1912, 371.)

Lythrum. *L. Salicaria* L. *Purple Loosestrife. Purple Willow-herb. Salicaire,* Fr. *Rother Weiderich,* G.—This is an elegant perennial herb of the Fam. *Lythraceæ,* a native of Europe, but naturalized from Quebec to Delaware. The dried herb is inodorous, and has an herbaceous, somewhat astringent taste. It is said to contain a glucoside, *salicarin,* which according to Caille (*P. J.*, 1920, civ) is the active principle. It has been used as a demulcent astringent in *diarrhea* and chronic *dysentery.* The *dose* of the powdered herb is about a drachm two or three times a day. A decoction of the root, prepared by boiling an ounce in a pint of water, may be given in the *dose* of two fluidounces (60 cc.).

Mace. *Macis. N. F. IV.*—"The arillode of the seed of *Myristica fragrans* Houttuyn (Fam. *Myristicaceæ*)." *N. F. IV.*

Mace was official in the U. S. Pharmacopœia 1890, and later in the National Formulary IV, but is now not recognized by either standard. It was described as follows: "In narrow bands, 25 mm. or more in length, somewhat branched and lobed above, united into broader bands; yellowish to brownish-orange, and oily. Odor fragrant; taste warm and aromatic.

"The powder is orange-buff to orange-brown. Mounted in water and examined microscopically, the powder exhibits elongated epidermal cells; parenchyma containing very small amylodextrin granules, which are colored red-brown by iodine T.S.; large oil cells the contents of which are not greatly changed in color on the addition of alkali.

"Powdered false Mace or Bombay Mace is yellow-brown to deep-brown in color and deficient in odor and taste. When mounted in water and examined microscopically it exhibits flattened, thick-walled epidermal cells and oil cells much more numerous than in true Mace and containing an orange-red resinous substance which is dissolved by alkalies forming a blood-red liquid.

"Moisten Mace with hydrochloric acid; no greenish color is produced (difference from and absence of the *arillode of Myristica malabarica* Lamarck or *Bombay Mace*). Add potassium chromate T.S. to an alcoholic extract of Mace (1 in 10); the precipitate formed is yellow and does not change to red on standing, nor does the solution develop a red coloration (difference from and absence of *Bombay Mace*). Saturate a piece of filter paper with an alcoholic tincture of Mace (1 in 10), and add one drop of potassium hydroxide T.S.; no blood-red coloration is produced (difference from and absence of *Bombay Mace*).

"Mace yields not less than 8 per cent. of volatile ether extract, and not less than 20 per cent. nor more than 30 per cent. of non-volatile ether extract. Mace yields not more than 3 per cent. of ash which is almost completely soluble in hydrochloric acid." *N. F. IV.*

Mace is inferior when it is brittle, less than usually divided, whitish or pale yellow, or with little taste and odor. The presence of starch granules or other microscopic particles different from those spoken of in powdered mace is proof of adulteration. Mace contains from 7 to 9 per cent. of a volatile oil, the greater portion of which consists of pinene, along with which is some *myristicin,* $C_{12}H_{14}O_3$. Wallach separated two odorous fixed oils; one yellow, soluble in ether, insoluble in boiling alcohol; the other red, soluble in alcohol and ether in every proportion.

Mackay Bean. (*Garbee Bean.*)—This is the seed of *Entada scandens* Benth. (Fam. *Leguminosæ*), a tropical woody climber; which has the reputation in Queensland of being strongly poisonous, and in which John Moss found saponin. (*P. J.*, vol. xviii, 242.) According to Raybaud (*C. R. S. B.*, 1921, lxxxv, p. 933), the *Entada Sudanica,* a small shrub found in French Equatorial Africa, yields an amber-colored gum of which 92 per cent. is soluble in cold water, the remainder acting like tragacanth.

Maculanin. *Potassium Amylate.*—Ogata Osaka (*D. M. W.*, 1907) prepares a caustic in the following manner: Well washed rice grains are scattered on the bottom of a glass dish, the latter being filled with a ten per cent. solution of potassium hydroxide and allowed to stand for six or eight hours, after which time the water is poured off, and the transparent mass rubbed up in a mortar. This is applied like a paste to the diseased tissue which has been previously cleansed.

Magnesium Benzoate. *Magnesii Benzoas.* $Mg(C_7H_5O_2)_2$.—A white, crystalline powder, permanent in the air, soluble in 20 parts of water or alcohol. Used for *gout, urinary calculi,* and *tuberculosis,* in *doses* of from three to fifteen grains (0.2–1.0 Gm.).

Magnesium Borate. $Mg(BO_2)_2.2Mg(OH)_2 + 7H_2O$.—This magnesium salt was primarily introduced under the trade name *antifungin.* It forms colorless micro-crystals possessing decided antiseptic value. It is used almost exclusively as a preservative, although it has been given as an internal antiseptic in *doses* of five to fifteen grains (0.32–1.0 Gm.).

Magnesium Bromide. *Magnesii Bromidum.* $MgBr_2 + 6H_2O$.—Made by neutralizing hydrobromic acid with magnesium oxide, evaporating and crystallizing. In the form of colorless, very deliquescent crystals, used as a nervine, in *doses* of from five to thirty grains (0.32–2.0 Gm.).

Magnesium Copaivate.—A yellowish powder, slowly soluble in alcohol and asserted to be an antiseptic, diuretic and laxative. It is used in *gonorrhea, leucorrhea* and *dysentery.*

Magnesium Glycerophosphate.—A white amorphous powder soluble in water, its solutions being neutral or faintly alkaline. It is used for the same purposes as the other glycerophosphates; *dose,* five to ten grains (0.3 to 0.6 Gm.).

Magnesium Hypophosphite.—White crystals, efflorescent, soluble in about 5 parts of water. It is used like the other hypophosphites. *Dose,* five to ten grains (0.3 to 0.6 Gm.).

Magnesium Iodide. $MgI_2 + 8H_2O$.—A deliquescent, crystalline powder melting at 45° C., and rapidly decomposing in aqueous solution. It is used as an alterative and sialagogue in the treatment of *scrofula, syphilitic* and *chronic rheumatism. Dose,* three to eight grains (0.2–0.5 Gm.).

Magnesium Lactate. *Magnesii Lactas.* $Mg(C_3H_5O_3)_2 + 3H_2O$.—In white, granular crystals, soluble in about 30 parts of cold water and 6 parts of boiling water, insoluble in alcohol. Used as a mild laxative in *doses* of from fifteen to forty-five grains (1–3 Gm.). A combination of magnesium lactate and magnesium phosphate known as *magnesium phospholactate,* is recommended as a tonic laxative. *Dose,* three to fifteen grains (0.2–1.0 Gm.).

Magnesium Perborate.—The exact composition of this salt is somewhat doubtful. The formula $MgBO_3 + 7H_2O$ has been suggested, but the commercial preparations rarely yield the amount of oxygen (11.9 per cent.) which would be indicated by such a compound. Magnesium Perborate is sparingly soluble in water with partial decomposition, the resulting solutions are faintly alkaline and contain hydrogen peroxide. It is used chiefly in the preparation of dentrifrices.

Magnesium Salicylate. *Magnesii Salicylas.* $Mg(C_6H_4(OH)CO_2)_2.4H_2O$.—This salt has been used as an intestinal antiseptic by Boas (*B. K. W.,* 1910, p. 89) in *intestinal fermentation,* and by Huchard in *typhoid fever.* The *dose* is from fifteen to thirty grains (1–2 Gm.) three times a day.

Magnesium Silicate. *Hydrated Magnesium Silicate. Meerschaum. Sepiolite. Ecume de Mer,* Fr. $3MgSiO_3 + 5H_2O$.—Meerschaum is one of several hydrated silicates of magnesium, asbestos, talc and serpentine being others of analogous formula. The most important deposits of meerschaum are in Anatolia, Asia Minor. It is used for the manufacture of tobacco pipes. It has been used as a substitute for bismuth subnitrate in *diarrhea* and has the advantage of not darkening the feces. It should be reduced to a very fine powder, and given in *doses* of from one to four drachms (3.9–15.5 Gm.) a day.

Magnesium Sulphite. *Magnesii Sulphis. U. S.* 1880. $MgSO_3.6H_2O$.—This salt may be prepared by double decomposition between magnesium sulphate and neutral sodium sulphite. Owing to the almost universal presence of sulphate in the sodium sulphite, J. P. Remington proposed to prepare it by suspending eight parts of pure magnesia in sixteen parts of water, and then adding gradually, with stirring, official aqueous sulphurous acid in excess. The crystals which form are washed with very cold water, drained, and dried. (*A. J. P.,* xl, 97.) "A white, crystalline powder, gradually becoming oxidized on exposure to air, odorless, having a slightly bitter, somewhat sulphurous taste, and a neutral or slightly alkaline reaction. Soluble in twenty parts of water at 15° C., and in nineteen parts of boiling water; insoluble in alcohol. When heated to 200° C., the salt loses its water of crystallization (50.9 per cent.), and is converted into magnesium oxide and anhydrous magnesium sulphate. The aqueous solution of the salt, mixed with ammonium chloride, yields, with excess of test-solution of sodium phosphate and water of ammonia, a white, crystalline precipitate soluble in acids. When treated with four times its weight of diluted hydrochloric acid, the salt dissolves completely and emits the odor of burning sulphur, without becoming cloudy (difference from hyposulphite). A one per cent. aqueous solution, strongly acidulated with hydrochloric acid, should not afford more than a slight cloudiness with test solution of chloride of barium (limit of sulphate)." *U. S.* 1880. Magnesium sulphite shares the general medicinal properties of the sulphites, but is better fitted for internal administration on account of its less solubility and less disagreeable taste, etc. (See *Sodii sulphis.*) The *dose* is from fifteen grains to half a drachm (1–2 Gm.).

Magnolia. *U. S.* 1880. *Magnolia Bark.*—Three species of *Magnolia* were formerly official as follows: *Magnolia glauca* L., *Small* or *Laurel Magnolia, M. acuminata* L. or *Cucumber-tree,* and *M. tripetala* L., commonly known as *Umbrella-tree* (Fam. *Magnoliaceæ*). In the fruit of the latter Wallace Procter found a neutral crystalline principle, *magnolin.* When pure, this is without odor and has at first little taste, in consequence of its insolubility in the liquids of the mouth, but after a time produces an irritant effect on the fauces. It is nearly insoluble in cold, but slightly soluble in hot water, very soluble in alcohol or ether. Procter considered it analogous to the liriodendrin obtained by Emmet, but quite distinct. It has been also found in other species. (See *A. J. P.,* 1872, 145; also Lloyd's paper in *Ph. Rund.,* 1866, 224.) W. F. Rawlins (*A. J. P.,* 1889, 7) obtained from the leaves of *M. glauca* a small quantity of a volatile oil of bright green color, with an odor resembling fennel or anise, but more pleasant. From the ethereal solution of this oil small crystals deposited. Indications were also obtained of a bitter glucosidal principle.

The bark and fruit of all the species of *Magnolia* are possessed of similar properties; but the bark only was official, and that of the root was thought to be most efficient. "The bark from young wood is quilled or curved, thin, externally orange-brown and glossy, or light gray, with scattered warts and somewhat fissured, internally whitish or pale brownish and smooth; fracture short, in the inner layer somewhat fibrous; inodorous; taste somewhat astringent, pungent, and bitter. The bark of old wood, deprived of the cork, is whitish or brownish, fibrous, and less pungent." *U. S.* 1880. The aromatic property, which resides in a volatile principle, is diminished by desiccation, and entirely lost when the bark is long kept. The bitterness, however, remains. The bark is destitute of astringency.

Magnolia is a gently stimulant aromatic tonic and diaphoretic. It has been used in *malaria* and in *rheumatism.* The *dose* of the recently dried bark in powder is from half a drachm to a drachm (2.0–3.9 Gm.), frequently repeated.

Malachite Green. *Tetra-methyl-diapara-amido-triphenyl-carbinol.*—(The term malachite green is usually applied to this coal tar dye although the native green copper carbonate has also been known as "malachite.") The closely allied *brilliant green,* or *diamond green* G., while by some considered identical, appears to be the sulphate of a compound similar to that above with the exception that the methyl groups are replaced by a tetra-ethyl. Malachite green of commerce occurs as either the zinc double chloride or double oxalate compound. The former is in brass yellow prismatic crystals while the latter is in green metallic-glistening plates. It is also called *benzaldehyde green.*

Malachite green is an active germicide but differs very greatly in its effects on various micro-organisms. Boer finds that one part in 40,000 destroys the anthrax bacillus in two hours and one in 8000 the diphtheria bacillus but that it requires one in 300 to destroy the typhoid bacillus. Fildes and Rajchman (*C. D.,* 1915, p. 156) find that one in 2000, is germicidal against the *Staphylococcus aureus.*

A number of surgeons have used it successfully as a wound antiseptic. According to Webb (*B. M. J.*, June, 1917, 870), it has the advantage of not interfering with granulation or phagocytosis. He uses a one to 1000 solution as a wound lavage and states that although it stains dead or nonvascular tissue (as the skin), it does not stain living vascular tissue. According to Löffler (*D. M. W.*, 1906, p. 269), it possesses such a marked influence over the *Bacillus coli communis* that it can be used as a means of separating this organism from the typhoid bacillus. Wendelstadt (*D. M. W.*, 1906, p. 863) has found it of service in the treatment of experimental trypanosomiasis, but we know of no clinical application of this result.

Malakin. *Phenosal. Salicyl-paraphenetidin.* $C_6H_4\left\{\begin{matrix}OC_2H_5\\ N:CH.C_6H_4(OH)\end{matrix}\right. + H_2O$.—This occurs in small, bright yellow, fine needles, melting at 92° C., insoluble in water, sparingly soluble in cold, but quite so in hot, alcohol, insoluble in carbonates of the alkalies, but soluble with a yellow color in sodium hydroxide solution. Weak mineral acids decompose it, forming salicylaldehyde and paraphenetidin.

Malakin contains about 57 per cent. of salicylic acid and 43 per cent. of phenetidin. In 1893 Jacquet called attention to it as an anti-rheumatic remedy, stating that it is decomposed in the stomach, yielding salicylaldehyde to the blood, and offering, therefore, a method of giving salicylic acid. On the other hand, while a number of clinicians have reported favorably of its effect in *acute rheumatism*, Ottolenghi (*Ther. Woch.*, ii, 1895) has found that the decomposition and after-absorption of it is exceedingly slow and uncertain. The contention of Bauer, that it is distinctly inferior to the older salicylates, is in all probability correct. Ottolenghi suggests that malakin must act on intestinal parasites, and may therefore prove useful as an anthelmintic. *Dose*, eight to fifteen grains (0.5–1.0 Gm.).

Malambo or Matias Bark.—A bark received from South America by Alex. Ure, under the name of *matias bark*, was found to have the characters of the *malambo bark*, which is held in high esteem in Colombia, where it is produced. According to H. Karsten, it is derived from a species of *Croton*, which he names *Croton Malambo* Karst. (Fam. *Euphorbiaceæ*). This is a small tree or shrub, growing on the coast of Venezuela and Colombia. The bark occurs in transversely curved pieces with a white outer and reddish-brown inner surface and a short fracture. It has a slightly aromatic odor and a bitter, pungent taste, and yields these properties to water and alcohol. Its active ingredients appear to be a volatile oil and a bitter extractive matter. Although formerly recommended as a febrifuge and antiperiodic it is probably nothing more than an aromatic tonic.

Malambo bark has been substituted for Winter's bark.

Malouetia. *Malouetia nitida* Spruce. *Guachamaca.* (Fam. *Apocynaceæ.*)—This plant, of Venezuela, contains an alkaloid, *guachamacine*, which Kobert believes to be identical with *curarine.* (*A. J. P.*, 1885, 560.)

Mandragora. *Mandragora autumnalis* Bertol. *Mandrake. Mandragora.* (Fam. *Solanaceæ.*)—A perennial, European plant, with spindle-shaped root, which is often forked beneath, and is therefore compared, in shape, to the human figure. In former times this root was supposed to possess magical virtues, especially when collected at certain times, and was used as an amulet to promote fecundity, etc., and the superstition is still cherished in some parts of Europe. The plant is a poisonous narcotic, somewhat similar in its properties to belladonna, to which it is botanically allied. See a paper by Ekert for the history of this drug. (*S. W. P.*, 1913, 425.) Crouzel isolated an alkaloid, *mandragorine*, which he found similar in properties to atropine. (*P. J.*, 1885, 1067.) Thoms and Wentzel (*B. Chem. G.*, 1901, xxxiv, p. 1023) state that this mandragorine is a mixture of hyoscyamine and scopolamine. Hesse (*J. P. C.*, 1901, lxiv, p. 274) finds in the plant, however, besides these two alkaloids a third substance to which the name mandragorine may be applied, $C_{15}H_{19}O_2N$.

Mandragora was much used by the ancients as a narcotic, and as an anesthetic agent before surgical operations. (*J. P. C.*, xv, 290.) *Morion* or *death-wine*, said to have been administered previous to the torture, was made from it.

Manganese. *Manganum.* Mn.—Atomic weight, 54.93. This element is a brittle grayish white metal, very hard, being capable of cutting glass and scratching tempered steel. It is susceptible of taking a high polish and has a specific gravity of 7.9. With oxygen it forms five or possibly seven compounds as follows—monoxide, MnO, of a light green color; sesquioxide, Mn_2O_3 (*braunite*), of a dark brown color; magnetic oxide, Mn_3O_4, which occurs in *hausmanite* as brownish black crystals; the dioxide MnO_2 described below; the highest oxide is acid forming yielding permanganic acid, $HMnO_4$ (see *Potassium permanganas.*) Manganese occurs in the mineral kingdom in the form of a silicate (*rhodonite*), as a carbonate (*rhodochrosite*) and as a dioxide (*pyrolusite*). The most abundant mines are in Russia, but it is also mined in various other countries. In the arts it is widely used in alloy with copper and zinc either as manganese bronze or German silver and for hardening steel.

Manganese is an occasional constituent of organic matter. It has been detected in minute quantity in various parts of the human body but is probably not a normal constituent of any human tissue. According to E. Davy, potassium hydroxide, dissolved in an equal weight of water, forms a delicate test for manganese, not obscured by the presence of other metals.

The citrate, glycerophosphate, and hypophosphite are recognized by the N. F. Several of its salts have been proposed as medicines, to be used as tonic and anti-anemic remedies.

Manganese Butyrate.—A solution of this salt has been brought forward as a remedy for *furunculosis* and other staphylococcic infections. The 1 per cent. solution is recommended to be injected intramuscularly in doses of fifteen minims (1 cc.); not more than two doses are to be given.

Manganese Carbonate. *Mangani Carbonas. Manganous Carbonate.* $MnCO_3$.—This salt may be obtained by double decomposition between molecular proportions of manganous sulphate and sodium carbonate, using the same precautions to prevent oxidation that are employed in making the preparations of ferrous carbonate. It is given in the form of pills of four or five grains (0.26–0.32 Gm.) each.

Manganese Chloride. *Mangani Chloridum.* $MnCl_2 + 4H_2O$.—Manganese chloride occurs as rose-colored deliquescent crystals. It has been used locally as a stimulant to *syphilitic* and other *indolent ulcers.* For process of preparing it, see *U. S. D.*, 19th ed., p. 1559.

Manganese Dioxide. *Mangani dioxidum. Mangani oxidum nigrum. Binoxide of Manganese. Manganese Peroxide, Manganum Hyperoxydatum; Oxydum Manganicum; Peroxide of Manganese; Deutoxide of Manganese, Black Oxide of Manganese, Pyrolusite; Braunstein,* G.

The U. S. P. 1890 recognized under the name of *Mangani dioxidum* the "native crude manganese dioxide." In the 8th revision this was substituted by a dioxide prepared by precipitation of manganese sulphate by a mixture of equal volumes of ammonia water and a solution of hydrogen peroxide. In the 10th revision the salt was entirely dropped. The *precipitated* Manganese dioxide (*Mangani Dioxidum Praecipitatum* U. S. IX) consisted "chiefly of manganese dioxide [MnO_2=86.93] with small amounts of other oxides of manganese, corresponding to not less than 80 per cent. of MnO_2." *U. S. IX.*

The formula for its preparation was as follows: "Manganese Sulphate, *fifty grammes;* Ammonia Water, *two hundred and fifty cc.;* Solution of Hydrogen Dioxide, *two hundred and fifty cc.;* Distilled Water, *a sufficient quantity.* Dissolve the manganese sulphate in *one thousand cc.* of distilled water. Dilute the ammonia water with an equal volume of distilled water, and mix it with the solution of hydrogen dioxide, which has also been diluted with an equal volume of distilled water. Pour the mixed solutions, slowly, with constant stirring, into the solution of manganese sulphate. Allow the mixture to stand for one hour, stirring frequently. Then decant the supernatant clear liquid from the precipitate, and wash the latter repeatedly by affusion and decantation with hot distilled water, using *one thousand cc.* each time. Collect the precipitate on a plain filter, and continue the washings with hot distilled water until the washings no longer have an alkaline reaction upon red litmus paper, and produce no turbidity when mixed with barium chloride test solution. Allow the precipitate to drain, then dry it at 150° C." *U. S. VIII.*

Manganese dioxide, as it occurs in nature, is very diversified in its appearance. Its sp. gr. varies from 4.7 to 4.9. It is found sometimes in brilliant needle-shaped crystals, often in compact masses having a metallic luster, but far more frequently in the form of a dull earthy-looking substance of a black or brown color. It is purest when crystallized. As it occurs in commerce, it is usually in the form of a black powder, insoluble in water, and containing more or less oxidized iron, calcium carbonate, barium sulphate, and earthy matter. Iron, which is rarely absent, is detected by the production of a green or blue tint on the addition of potassium ferrocyanide to its hydrochloric acid solution. When exposed to a red heat it yields a portion of its oxygen, and is reduced to manganoso-manganic oxide. Hence its use in obtaining that gas. Good samples, after being dried, lose, when heated to a whiteness, 12 per cent. of oxygen. It is distinguished from antimony sulphide which it physically resembles by its infusibility, and by causing the evolution of chlorine on being heated with hydrochloric acid. When of a brown color, it is not of good quality.

The U. S. Pharmacopœia described the precipitated manganese dioxide as "a heavy, very fine, black powder, without odor or taste; permanent in the air. It is insoluble in water or alcohol. When heated with hydrochloric acid, it is converted into manganous chloride and chlorine is evolved. At a red heat Precipitated Manganese Dioxide gives off oxygen and is converted into reddish-brown manganous-manganic oxide (Mn_3O_4). Add 2 drops of hydrochloric acid to about 0.1 Gm. of Precipitated Manganese Dioxide contained in a test tube, boil the mixture for one minute with 0.5 Gm. of lead peroxide and 5 mils of nitric acid and then add 5 mils of distilled water; the liquid assumes a reddish-violet color. Add 20 mils of distilled water to 1 Gm. of Manganese Dioxide and 2 Gm. of oxalic acid, follow this by 3 mils of sulphuric acid, and digest the mixture for several hours on a water bath; not more than 0.2 per cent. of residue remains (*insoluble substances*).

"Dissolve about 0.2 Gm. of Precipitated Manganese Dioxide, accurately weighed, in a mixture of 50 mils of tenth-normal oxalic acid V.S. and 3 mils of sulphuric acid, heat to 80° C. on a water bath, and titrate the residual oxalic acid with tenth-normal potassium permanganate V.S. It shows not less than 80 per cent. of MnO_2.

"Each mil of tenth-normal oxalic acid V.S. used corresponds to 0.0043465 Gm. of MnO_2. Each gramme of Precipitated Manganese Dioxide corresponds to not less than 184 mils of tenth-normal oxalic acid V.S." *U. S. IX.*

This salt appears to possess some stimulant action upon the uterine mucosa and is still used in the treatment of *amenorrhea.* Its ancient employment in *syphilis, scurvy,* and various *skin diseases,* does not appear to be founded on any rational basis.

The native oxide is used in the arts for obtaining chlorine in the manufacture of bleaching powder, for giving a black glazing to pottery, and for freeing glass from the color which it derives from iron. In the laboratory it is employed to obtain oxygen and chlorine, and to form the salts of manganese. It is also used for liberating chlorine from hydrochloric acid and from sodium chloride, and iodine from sodium iodide contained in kelp.

Dose, three to ten grains (0.2–0.65 Gm.).

Manganese Iodide. *Mangani Iodidum. Manganous Iodide.* MnI_2.—This very deliquescent salt may be prepared by adding manganese carbonate to aqueous hydriodic acid, filtering the solution, and granulating, carefully regulating the heat. This iodide may be administered in syrup or pill. For formula for these, see *U. S. D.*, 19th ed., p. 1559. According to Hannon, manganous iodide is particularly useful in the *anemia* attendant on *scrofula, phthisis,* and *cancer,* and in *syphilis.* It is also affirmed that when given with cinchona it removes the enlargement of the spleen of malarial fevers. *Dose,* two to four grains (0.12–0.25 Gm.).

Manganese Lactate.—This occurs as a pinkish powder or granules soluble in about ten parts of water. It has been used as a hematinic in *doses* of from one to five grains (0.06 to 0.3 Gm.).

Manganese Peptonate. *Peptonized Manganese.*—This is a brown powder representing about 3 per cent. of manganese. It is soluble in water. It has been used in the treatment of anemias in *doses* of ten to thirty grains (0.6–2.0 Gm.) (see also *Liquor Ferri Peptonatum et Mangani*).

Manganese Phosphate.—*Manganese Ortho-*

phosphate. Under the name of Manganese Phosphate is furnished either the dibasic or tribasic salt, although the latter seems to be the one most frequently intended. It is a pink powder insoluble in water but soluble in diluted mineral acids. It is employed usually in conjunction with iron in the treatment of *anemia,* in *doses* of one to five grains (0.06 to 0.3 Gm.).

Manganese Sulphate. (*U. S. P. VIII*). *Mangani Sulphas. Manganesii Sulphas. U. S.* 1870. *Manganum Sulphuricum. Schwefelsaures Manganoxydul,* G.—"It contains not more than 38 per cent. of water, and not less than 62 per cent. nor more than 68 per cent. of $MnSO_4$ (151.00)." *N. F. IV.*

This salt is no longer official in either the U. S. P. or N. F. It may be prepared by heating the native black oxide with concentrated sulphuric acid. For details of several methods of manufacture, see *U. S. D.*, 19th ed., p. 762. From its aqueous solution it crystallizes in rhombic prisms, which contain variable proportions of water of crystallization according to the temperature of the solution and other circumstances. "Manganese Sulphate occurs as pale rose-colored, translucent, tetrahedral prisms; slightly efflorescent when exposed to moist air. Odorless; taste slightly bitter and astringent. One gramme of the salt dissolves in about 1 cc. of water at 25° C., and in about 0.6 cc. of boiling water; insoluble in alcohol. An aqueous solution of the salt (1 in 20) is neutral or slightly acid to litmus." *N. F. IV.* For further tests see *U. S. D.*, 20th ed., p. 1483.

At one time manganese sulphate was said to be an active cholagogue and purgative, but it has failed to come into use as such. According to Thomas Thomson, of Glasgow, it resembles sodium sulphate both in taste and in effect, operating as a purgative in the dose of from one to two drachms (3.9–7.5 Gm.). A trial was made of it in *anemia,* as an adjuvant of the chalybeates, but the results have not been satisfactory and it is at present rarely given. *Dose,* as a tonic, from five to twenty grains (0.32–1.3 Gm.).

Mangosteen.—The pericarp of the fruit of *Garcinia Mangostana* L. (Fam. *Guttiferæ*), a handsome fruit tree widely cultivated in tropical countries. It is sometimes substituted for bael fruit (see *Belæ Fructus,* Part I). It is an active astringent, and has been used as such locally in various *catarrhs,* and also in *diarrhea* and in *leucorrhea.* Ambrose has used the toasted and pulverized rind of mangosteen in the treatment of tropical *dysentery* with asserted benefit. He gives *doses* of one drachm (4 Gm.) every two hours. The activity of the drug appears to reside in the neutral principle *mangostin. Dose,* of fluidextract, from half to one fluidrachm (1.8–3.75 cc.).

Manzanillo. *Manchineel. Hippomane Mancinella* L.—According to A. Betancourt, the milky juice of this euphorbiaceous tree, found near the coasts of Central America, West Indies and adjoining South America and Southern Florida, is a violent irritant, acting as a vesicant when applied to the skin, and when taken internally in doses of twenty drops causing a fatal gastroenteritis. In *doses* of two drops it acts as a powerful and very certain cathartic; it is also diuretic. In Cuba it has much repute in *tetanus.* (*L. M. R.*, Feb., 1889.)

Maranta. *Arrowroot. Arrowroot Starch.* (Fam. *Marantaceæ.*)—Under this name the U. S. Pharmacopœia, 1870, recognized the fecula or starch obtained from the rhizome of *M. arundinacea,* L.

The arrowroot plant is a native of the West Indies, where it is largely cultivated for the sake of its fleshy, irregularly cylindrical rhizomes whose cells are gorged with starch granules. It is cultivated also in the East Indies, Ceylon, Sierra Leone, and south of Africa, and formerly in our Southern States, especially Georgia and Florida. The plant is easily propagated by cuttings of the root. An analysis by Macdonald (*J. Soc. Chem. Ind.*, 1887, 336) gives the following as the composition of the St. Vincent root: Starch, 27.07 per cent.; fiber, 2.82; fat, 0.26; albumen, 1.56; sugar, gum, etc., 4.10; ash, 1.23; water, 62.96; total, 100.00. An analysis of the arrowroot starch from the same locality by Macdonald gave: Starch, 83.70 per cent.; fiber, 0.04; fat, 0.07; sugar, gum, etc., 0.18; ash and sand, 0.14; water, 15.87; total, 100.00. The fecula is prepared in the following manner. The rhizomes are dug up when a year old, washed, and then beaten into a pulp, which is thrown into water, and agitated so as to separate the amylaceous from the fibrous portion. The tissues are removed by the hand, and the starch remains suspended in the water, to which it gives a milky color. The milky fluid is strained through coarse linen, and allowed to stand that the starch may subside, which is then washed with a fresh portion of water, and afterwards dried in the sun.

The *Bermuda arrowroot* was formerly the most highly esteemed, but the production of it in the island has almost ceased. It occurs in somewhat hard and irregular whitish masses which when rubbed between the fingers are reduced to a smooth powder.

St. Vincent arrowroot is the variety now in the ascendency on the market. It differs from the Bermuda arrowroot in being slightly darker in color and in having many of its masses of grains larger than the preceding variety. For a list of other sources of arrowroot of commerce during different periods, see *U. S. D.*, 19th ed., p. 1561.

A spurious form, called *Florida arrowroot,* is derived from the stem of the *Zamia integrifolia* Willd. Langworthy and Denel (*J. Bi. Chem.*, 1922, lii, 251) have shown this is less easily digested.

Arrowroot starch is in the form of a light, white powder, or of small pulverulent masses, without odor or taste. It is firm to the touch when pressed between the fingers, and produces a faint creaking sound when rubbed. It is liable to become musty, and should then be rejected. The odor and taste are the best criteria of its quality. It should be perfectly free from odor and unpleasant flavor.

The microscope offers the best means of distinguishing the different varieties of fecula sold as arrowroot, or used for its adulteration. The grains of *Maranta arrowroot* are ovoid to ellipsoidal or oblong, from 10 to 70 microns in length with very fine, often indistinct, lamellæ, and a hilum varying from a circular to a linear or crescent-shaped cleft, situated in the center or toward the broad end of the grain. St. Vincent arrowroot exhibits grains with the larger number of transverse or crescent-shaped clefts.

Arrowroot affords a light, very mild, and easily digested article of diet, well adapted for the sick and convalescent, and peculiarly suited, from its demulcent properties, to bowel complaints. It is prepared by dissolving it in hot water or hot milk, with either of which it forms a pearly, gelatinous solution, and, if in sufficient quantity, a jelly-like mass on cooling. A tablespoonful will communicate sufficient consistence to a pint of water. It should first be formed into a perfectly smooth paste with a little cold water or milk, and the boiling water then gradually added with brisk agitation. The preparation may be then suitably flavored and sweetened.

Maretin. *Metatolyl-hydrazine-carbaminate.* $C_6H_4.CH_3.NH.NH.CONH_2$.—This may be regarded as a methyl-acetanilid in which the acetyl group is replaced by the carbamic group $NH.CONH_2$. It occurs as white, tasteless crystals practically insoluble in water or ether but readily dissolved by chloroform or acetone. It is claimed for the compound that the urea nucleus is so firmly combined that aniline is not liberated in the body; nevertheless, its effects are very similar to those of the other aniline derivatives. It has been used as an antipyretic and analgesic and is especially recommended in *acute articular rheumatism.* Heubner (*Th. M.*, 1911, xxv, p. 364, and 1913, p. 507) asserts that when used over long periods of time it causes destruction of the blood cells and may lead to a dangerous degree of anemia. The *dose* is from one and one-half to four grains (0.96–0.26 Gm.).

Marrubium. *Hoarhound. Horehound. White Hoarhound. Marvel. Herba Marrubii. Marrube Blanc,* Fr. Cod. *Andornkraut, Weisser Andorn,* G. *Marrubio,* It., Sp.—The U. S. P. formerly recognized "The dried leaves and flowering tops of *Marrubium vulgare* Linné (Fam. *Labiatæ*)." *U. S. VIII.*

Horehound has a perennial, fibrous root, and numerous erect, woolly annual stems, from twelve to eighteen inches high. The leaves are about 2.5 cm. long, roundish-ovate, crenate, wrinkled, downy above, hoary on the under surface, and supported in pairs on strong foot-stalks. The flowers are white, and in crowded axillary woolly whorls. Each consists of a sparsely hairy, tubular calyx with 10 hooked, bristle-like teeth, a bilabiate corolla, 4 parallel stamens and a bi-carpellary pistil with a 4-celled ovary.

Horehound has been adulterated with the leaves and flowering tops of *Ballota hirsuta* Benth., *Ballota nigra* L., *Marrubium peregrinum* L. and *Marrubium candidissimum* L. From all of these it may be readily distinguished by its characteristic calyx. *Ballota hirsuta* has been the most common recent adulterant. For detailed structural differences between *Marrubium* and *Ballota hirsuta* see article by H. W. Youngken in *A. J. P.*, 1919, pp. 147–156.

Horehound contains a volatile oil, resin, tannin, and a bitter principle called *marrubiin.* This marrubiin is slightly soluble in cold water, crystallizes from alcohol in prismatic and from ether in tabular crystals, is not precipitated by tannin, and has a very bitter and somewhat acrid taste. The fusing point of the crystals is 160° C., according to Kromayer. Matusow (*A. J. P.*, 1897, 201). He gives to it the formula $C_{30}H_{43}O_6$, and states the melting point of the purified substance to be from 154° to 155° C. According to him, it is not a glucoside.

Hoarhound is tonic, and in large doses laxative. It was formerly considered a valuable deobstruent, and was recommended in *chronic hepatitis,* and various other affections but it exerts no influence over any of them, and has passed mainly from the hands of physicians into domestic use, where it is used in the form of a confection for *sore throat.* It is employed occasionally in *bronchitis* with copious expectoration. The infusion, made in the proportion of an ounce of the herb to a pint of boiling water, may be given in wineglassful doses.

Dose, thirty grains to a drachm (2.0–3.9 Gm.).

Massoi Bark. *Lawang.*—In Eastern commerce, certain aromatic barks have occurred under the name of massoi barks. Of these, three are believed by F. Hekmeyer to be the products respectively of *Cinnamomum xanthoneurum* Blume, *Cinnamomum Burmanni* Blume (*C. Kianis* Nees), and *Massoja aromatica* Becc. (*Sassafras gœsianum* Teijsm. and Binn.), all of the Fam. *Lauraceæ.* For a description of these barks, by E. M. Holmes, see *P. J.*, 1888, 465. The *massoi bark* which comes from New Guinea, and from which Messrs. Schimmel have distilled an oil resembling that of nutmeg and cloves, probably has a different origin from the true massoi bark which has a cocoanut-like odor. (*Y. B. P.*, 1912, 473.)

Medeola. *Medeola virginiana* L. (*Gyromia virginiana* L.) *Indian Cucumber.*—An indigenous perennial herb of the Fam. *Liliaceæ,* growing in many parts of the United States. The tuber, which in shape and flavor bears a strong resemblance to a small cucumber, is said to have been eaten by the Indians, and was used by Barton to be useful as a diuretic in *dropsies.*

Melaleuca.—Under the names of *gomenol* and *Niaouli oil* there has been put upon the market a volatile oil obtained from the leaves of *Melaleuca viridiflora* Brong. and Gris., a tree growing in upper India, the islands of the Indian Ocean and Australia. Its sp. gr. is 0.922, and its rotatory power plus 0.42°. Its odor and taste are said to resemble those of camphor and peppermint. The chief constituent of the oil (66 per cent.) is cineol, and in addition to this is a crystallized terpineol, $C_{10}H_{18}O$, and the valeric ester of the same. These together make up 30 per cent. additional. It has been recommended in the *chronic catarrhs* of the pulmonary mucous membrane, and especially in *whooping cough* (see Carrière, *B. A. M.*, 1922, lxxxviii, 30). It may be given by the mouth or exhibited in the form of intramuscular injections being diluted with from four to ten parts of a sterilized fixed oil to one part of volatile oil. The hypodermic *dose* of a 10 per cent. solution is two and one-half fluidrachms to one-half fluidounce (9.3–15.0 cc.). The injections should be practised every other day. Gomenol has been used by Brimont (*Press. Med.*, 1910, p. 800) as a vermifuge in *ankylostomiasis,* in *doses* of five minims (0.3 cc.).

Melastoma. *Melastoma Ackermanni.*—This Colombian plant of the Fam. *Melastomaceæ* is used in South America as an antineuralgic. Its abundant essential oil resembles methyl salicylate, if indeed it be not identical with it. (See *N. R.*, Aug. and Sept., 1883.)

Meligrin.—This is a condensation product of dimethyloxyquinine and methylphenyl acetamid. It occurs as a white crystalline powder with a slightly burning, though not bitter taste. It is very soluble in water and is employed in the treatment of *migraine* and *neuralgia.*

Melissa. *U. S.* 1890. *Melissa. Common Balm.*—Under this name were formerly recognized by the U. S. P. the leaves and tops of *Melissa officinalis* L. (Fam. *Labiatæ*), the ordinary *balm* of Southern Europe, which has become naturalized in this country. Balm contains some tannic acid, and a yellowish, highly flavored essential oil which, however, is present in such small quantities that the plant has practically no remedial value. The allied *Satureja Calamintha* (L.) Scheele, var. *sylvatica* Brig., is said to contain sufficient aromatic volatile oil to be of possible commercial interest.

Under the name of *oil of lemon balm* or *oil of balm* the essential *oil of melissa* has been used as a diaphoretic in doses of from one to three minims (0.06 to 0.2 cc.). This oil is a yellow liquid with a specific gravity of 0.9 to 0.925. Its most important constituent is citral.

Melubrin. *N. N. R.* 1924. *Sodium Salt of phenyldimethylpyrazolon-amidomethansulfonic acid.* $C_{11}H_{11}N_2ONHCH_2SO_3Na$.—This occurs as a white crystalline powder, readily soluble in water, with difficulty in alcohol, and is almost tasteless. It has been brought forward as an antipyretic, antirheumatic and analgesic. According to Loening (*M. M. W.*, 1912), its effect in *acute rheumatic fever* is that of a specific. In its medical properties it seems to resemble antipyrine. The *dose* is fifteen to thirty grains (1–2 Gm.).

Under the name of *Novalgin*, a related, but not identical, compound has also been brought forward as an antirheumatic.

Menispermum. *U. S.* 1890. *Yellow Parilla. Canadian Moonseed. Texas Sarsaparilla.*—"The rhizome and roots of *Menispermum canadense* Linné (fam. *Menispermaceæ*)." *U. S.*, 1890.

M. canadense L.—This is a woody, climbing plant, which grows from Western Quebec and New England southward. It is specifically characterized by its peltate, three to seven-lobed leaves, its small clusters of greenish-yellow flowers, and its somewhat kidney-shaped, glaucous fruit, which is ripened in September. Menispermum was officially described as follows: "Rhizome 5 to 6 dm. long, 5 mm. thick, brown or yellowish-brown, somewhat knotty, finely wrinkled longitudinally and beset with numerous thin, rather brittle roots; fracture tough, woody; internally yellowish, the bark rather thick, the wood-rays broad, porous, and longest on the lower side; pith distinct. Nearly inodorous; taste bitter." *U. S.* 1890. Maisch found a white alkaloid, which he called *menispine* and a small quantity of berberine. H. L. Barber (*A. J. P.*, 1884, p. 401) obtained the white amorphous alkaloid for which Maisch proposed the name *menispine*. But H. M. Gordin states that berberine is not present in menispermum. (*Proc. A. Ph. A.*, 1909.) Menispermum has been used as a substitute for sarsaparilla but is probably inert. A *fluidextract* made with a menstruum of 2 parts of alcohol and one part of water was recognized by the U. S. P. 1890; *dose*, one-half to one fluidrachm (1.8–3.75 cc.).

Menosal. *Menthyl-salicylic-methyl ester, Methyl menthylsalicylate.* $C_{18}H_{26}O_3$.—This occurs as an oily, transparent liquid almost free from odor and taste. It is soluble in alcohol, ether, chloroform, and fatty oils, and has a specific gravity of about 1.037; it boils at 189° C. at 17 mm. Menosal is said to pass through the stomach unchanged, the salicyl radical being liberated in the intestines, thereby avoiding any gastric irritation. It is given as an antirheumatic in doses of 3 minims and it may also be employed externally in admixture with a suitable vehicle.

Mensalin. *Diphenyldioxycarbonate of Dimethylpyrazolonhexahydrocymolvalerate.*—This forms a white, hygroscopic powder and is recommended as a nervine and in the treatment of *painful menstruation.*

Mentha Aquatica L.—Under the name of *poco oil*, the volatile oil of this plant, which is a native of China, is used in the Island of Java as a popular remedy for *headache*, and also in *cholera.*

Mentha Pulegium L.—*European Pennyroyal. Pouliot commun*, Fr. *Polei*, G. *Pulegium vulgare* Mill. (Fam. *Labiatæ*).—This European labiate yields an oil which is known in England as the *oil of pennyroyal*, and must not be confounded with the American oil of the same name and which is yielded by *Hedeoma pulegioides* Pers. The oil, which is also known as the *oil of poley*, has been examined by Beckmann and Pleissner (*Ann. Ch. Ph.*, ccii, 1), who discovered as the most important constituent *pulegone*, $C_{10}H_{16}O$, an unsaturated ketone, which makes up 80 per cent. of the oil. The oil contains besides pulegone small quantities of l-limonene, dipentene, menthol and menthone. Its constants are sp. gr. 0.930 to 0.955; opt. rot. +15° to +25°; ref. ind. 1.4810 to 1.4865. The boiling point of pulegone is 221° C. Pulegone forms crystalline compounds with hydroxylamine and with hydrogen bromide. When reduced by sodium in ethereal solution pulegone is changed into menthol. Pulegone is most abundant in the Spanish oil, and less abundant in American and Algerian oils. (See also Wallach, *Ann. Ch. Ph.*, cclxxii, 122, and Semmler, *B. Chem. G.*, xxv, 3515.) Schimmel states that the oil is sometimes adulterated with eucalyptus oil. (*Schim. Rep.*, 1908, 67.) It is stated (*B. M. J.*, March, 1890) that the oil is largely used for the purpose of producing abortion, and is popularly believed to be safer and more certain than the other volatile oils. Taylor denies, however, that the oil is an abortifacient and it appears to be demonstrated that it is capable of causing fatty degeneration. (See *S. Jb.*, cclxvii, p. 230.)

Menthospirin. *Menthol Acetylsalicylate.*—It is a yellowish thick fluid, insoluble in water but soluble in alcohol, ether, and the fixed oils. It is used internally by Loewenheim (*Med. Klin.*, 1913) in the treatment of *colds* and various *catarrhs*, both acute and subacute, of the upper respiratory tract. It has also been employed locally in *laryngeal tuberculosis*. The *dose* is from eight to twelve grains (0.5–0.78 Gm.) several times a day, usually in capsules or pearls.

Menthyl Camphorate.—The camphoric ester of menthol, which forms a white powder which is insoluble in water and chloroform but soluble in alcohol and the fatty oils. Hot water decomposes it with the liberation of menthol. It is used in *tuberculosis.*

Menyanthes. *Buckbean. Marsh Trefoil. Bogbean. Water Shamrock. Folia trifolii Fibrini.*—The dried leaves of *Menyanthes trifoliata* Linné (Fam. *Gentianaceæ*). This perennial herb is a native both of Europe and Asia. It has become naturalized in North America, from Greenland to Alaska and south to Pennsylvania, Minnesota, and California. The leaves were formerly recognized by the N. F. They are collected in late spring and carefully dried.

It was described by the N. F. IV as "glabrous; petioles from 10 to 15 cm. in length, stout but soft and weak, the base more or less sheathed with broad, thin, and membranaceous, somewhat translucent stipules; blade ash-green, trifoliate; leaflets sessile or very short-petioled from 5 to 8 cm. in length and usually about two-thirds as broad, obovate, blunt, entire or occasionally coarsely and unequally crenate. Odor slight but characteristic; taste decidedly bitter. Menyanthes yields not more than 10 per cent. of ash." *N. F.* Its virtues depend on a bitter glucoside denominated *menyanthin,* which has a bitter taste, is soluble in alcohol and water, but not in pure ether, and is chemically neutral. Kromayer (1865) assigned to it the formula $C_{30}H_{46}O_{14}$, and stated that it breaks up on heating with diluted sulphuric acid into a fermentable sugar and *menyanthol,* a colorless difficultly volatilizable oil, with an odor like that of bitter almond. K. Leuderich (*A. Pharm.,* 1892, 38 and 48) has studied menyanthin, and gives it the formula $C_{33}H_{50}O_{14}$, and states that its decomposition products are a phenol-like body, menyanthol, $C_7H_{11}O_2$, a resinous product, and a left-rotatory sugar.

Vridevel (*P. J.,* 1910, lxxxv, p. 465) has separated a second glucoside from menyanthes, to which he gives the name of *meliatin.* It is a crystalline body, with a melting point of 217° C.

With the ordinary properties of the bitter tonics, menyanthes unites a cathartic power; in large doses it may cause vomiting. The *dose* of the powdered leaves or roots as a tonic is from twenty to thirty grains (1.3–2.0 Gm.); of an infusion, prepared with half an ounce to a pint of boiling water, from one to two fluidounces (30–60 cc.); and of the extract, ten or fifteen grains (0.65–1.0 Gm.), to be repeated three or four times a day. A drachm of the powder, or four fluidounces of the strong decoction, generally purges, and often occasions vomiting.

Merbaphen. *Novasurol.*—The double salt of sodium oxymercuric-chlorphenoxylacetate with diethylbarbituric acid. This organic compound is stated to contain 33.9 per cent. of mercury in a non-ionizable combination. It is marketed only in the form of a solution containing 10 per cent. of the drug.

This preparation was originally introduced for the treatment of *syphilis* by intramuscular injection. It has been claimed for it that it is much less toxic or locally irritant than the soluble mercurials and is better absorbed than the insoluble salts. More recently it has been observed that it possesses the diuretic powers of the mercurials and a number of clinicians have reported favorable results in *dropsies,* especially when due to cardiac insufficiency (see Neuhof, *T. G.,* January 15, 1924). The reports of Burwinkel (*M. M. W.,* 1922, lxix, 202) and others show, however, that while an active diuretic it is capable of causing serious mercurial poisoning in improperly selected cases.

It is recommended that the beginning dose be 0.75 cc. (12 minims) of the 10 per cent. solution which may be gradually increased if the patient shows no intolerance, up to 2 cc. (30 minims) once or twice weekly.

Mercuramine. *Mercury Ethylenediamin Citrate.*—This is a solution of 10 parts of mercury citrate and 4 parts of ethylenediamine in 86 parts of distilled water. Its 0.3 per cent. dilution is asserted to be equal in bacterial value to a 1 in 1000 solution of mercuric chloride.

Mercurialis. *Mercurialis annua* L. *Mercury Herb. French Mercury.*—An herbaceous European plant (Fam. *Euphorbiaceæ*) which has been employed from the most ancient times as a purgative, diuretic, and emmenagogue. When boiled, it loses its acridity, and in this condition has been used as an emollient. Another species, *M. perennis* L., or *dog's mercury,* also a native of Europe, is poisonous. Its leaves yield an unstable blue dye. Reichardt has discovered in *M. annua* a volatile alkaloid, which he named *mercurialine.* According to E. Schmidt (*P. J.,* vol. x, 29), *mercurialine* is identical with *methylamine,* CH_3NH_2, and is associated in the mercurialis with trimethylamine. It is a liquid of an oily appearance, narcotic odor, and alkaline reaction; boils at 140° C.; forms salts with the acids; absorbs carbon dioxide; has a strong affinity for water; on exposure to the air it is changed into a resin of a buttery consistence, and is said to be poisonous to man; but Hugo Schulz (*A. E. P. P.,* April, 1886, 88) found that neither the fluidextract nor the herb given as food was capable of killing either the pig or the rabbit, and that four and a half grains (0.29 Gm.) of the mercurialine hypodermically injected had no effect. Hoffmann (*P. J.,* 1919, cii, 426) has ascribed poisoning in horses to eating hay containing mercurialis. The urine is increased in quantity and colored reddish.

Mercuric Acetate. $(CH_3COO)_2Hg$.—Colorless, laminar crystals, soluble in 4 parts of water, also in alcohol and ether. Used internally as an antisyphilitic in *doses* of one-sixth to one grain (0.010–0.065 Gm.).

Mercurialized Serum. *N. N. R.* 1924.—In syphilitic diseases of the nervous system, especially of the spinal cord, mercury frequently fails to arrest the progress of the disease. This has been attributed to the inability of the mercury to penetrate into the central nervous system. With the idea of introducing mercury directly into the cerebro-spinal tract by intraspinal injection, a mercurialized serum has been prepared by treating normal horse serum with mercuric chloride and redissolving the precipitate in an excess of serum. (For method of preparation see Byrnes, *J. A. M. A.,* 1914, lxiii, p. 2182). It is upon the market only in the form of dosage packets which are made of various strengths, the stronger intended for intramuscular injection and the more dilute for intraspinal.

Mercuric Aminosuccinamate. *Mercury Asparaginate. Hydrargyri Aminosuccinamas. Asparagin Mercury.* $Hg(C_4H_7N_2O_3)_2$.—Made by dissolving mercuric oxide in a warm solution of amido-succinamic acid, or asparagin, and setting aside to crystallize. Colorless, needle-like crystals, insoluble in water, soluble in dilute acids. It is used hypodermically in the treatment of *syphilis* and is asserted to produce less irritation at the site of injection than other salts of mercury. The *dose* is one-twelfth to one-sixth of a grain (0.005–0.010 Gm.).

Mercuric Anilinate. *Hydrargyri Anilicum.* $Hg(C_4H_4.NH_2)_2$.—It is prepared by the action of a solution of bichloride of mercury on aniline and forms a white, micro-crystalline, odorless and tasteless powder containing 52.1 per cent. mercury. It is insoluble in water. Fedtscheutig has used this salt with success both hypodermically and by mouth in the treatment of *syphilis.* Hypodermically it may be given in a white oil suspension and by mouth, in a pill. It has also been used as an inunction with oleic acid and resorbin.

Dose, one-fourth of a grain (0.015 Gm.).

Mercuric Arsenate. $Hg_2H_2(AsO_4)_2$.—A yellow powder soluble in acids and insoluble in water. It is used in the treatment of *syphilis.* The *arsenite of mercury* (*mercurous arsenite*), Hg_3AsO_3, a brownish powder, soluble in acids and insoluble in water, is used in *syphilis.*

Mercuric Benzoate. *N. N. R.* 1924.—*Hydrargyri Benzoas,* $Hg(C_6H_5COO)_2 + H_2O$, is obtained by double decomposition between an alkaline benzoate and a mercuric salt; it is a white crystalline, odorless, and tasteless powder, which is sparingly soluble in water, but easily in alcohol as well as in aqueous solutions of sodium chloride, the latter effect being due to its property of forming easily soluble double salts with the haloids. E. Seger states that this solution quickly decomposes into mercuric chloride and sodium benzoate and is an incompatible mixture. (*Repertoire de Pharmacie,* 1919, ciii, 13.) R. W. Terry states that the mercuric benzoate of commerce is not a definite substance and confirms Seger's statement as to the reaction with sodium chloride (*Midland Druggist,* 1919, liii, 222). This salt is incompatible with acids, iron compounds and acid salts. It has been strongly recommended by Stukowenkow as a substitute for mercuric chloride, for intramuscular injections in *syphilis* and as a local remedy in *gonorrhea.* For urethral injections the solution may be 1 to 1000 or 2000, with an equal quantity of sodium chloride. The *dose* for intramuscular injection is from one-eighth to one-fourth of a grain (0.008–0.015 Gm.) every second day.

Mercuric Bromide ($HgBr_2$) *Mercury Dibromide.*—This is in the form of colorless crystals, or silvery lustrous scales, sparingly soluble in water, freely soluble in alcohol. Exposed to heat it melts and sublimes. This salt has been used in the treatment of *syphilis. Dose,* one-fifteenth to one-eighth of a grain (0.004–0.008 Gm.).

Mercuric Cyanide. *N. N. R.* 1924. *Hydrargyri Cyanidum. U. S.* 1890. $Hg.(CN)_2 = 252.62$. *Hydrargyri Cyanuretum. U. S.* 1850. The process for the preparation of this substance, given in the U. S. P., 1850, is based upon the following: Hydrocyanic acid is generated by the action of sulphuric acid on potassium ferro-cyanide, and, being received in a vessel containing water and a portion of mercuric oxide, reacts with the oxide, according to the reaction

$$(HCN)_2 + HgO = Hg(CN)_2 + H_2O$$

generating, by double decomposition, water, and mercuric cyanide which is held in solution. Sufficient mercuric oxide is not used at first to saturate the whole of the hydrocyanic acid generated, because should there happen to be any excess of the oxide there would be produced on evaporation, instead of the substance wanted, a peculiar salt composed of cyanide and mercuric oxide, which would crystallize in small acicular crystals. Hence a portion of the water still containing uncombined hydrocyanic acid is set aside, to be added to the liquid in which the acid had been completely saturated by the addition of mercuric oxide, and thus at least neutralize any mercuric oxide that might be present in it in excess. A surplus of hydrocyanic acid would not be detrimental, except for the loss of material incurred, as it is evaporated in the subsequent concentration. Mercuric cyanide should be kept in well-stoppered, dark amber-colored bottles.

It occurs as colorless or white, prismatic crystals, odorless, and having a bitter, metallic taste (the salt is exceedingly poisonous), becoming dark-colored on exposure to light. Soluble, at 15° C., in 12.8 parts of water, and in 15 parts of alcohol in 3 parts of boiling water, in 6 parts of boiling alcohol; very sparingly soluble in ether. It is often contaminated with the oxycyanide. The presence of the latter may be shown by the production of a white precipitate by ammonia.

Mercuric cyanide has been brought forward as a substitute for corrosive sublimate especially for germicidal purposes. The experiments of various investigators show that the antibacterial properties are much inferior to those of the bichloride. According to Hüne (*Desinfektion,* 1912, v), it requires a 1 in 1000 solution of mercuric cyanide to kill the staphylococci in thirty minutes, which corrosive sublimate will do in 1 in 10,000 solution, and Harrington (*B. M. and S. J.,* January 14, 1904) found that a 1 in 500 solution was not certainly fatal to the pus-forming organisms in thirty minutes.

Prochorow has used it hypodermically without causing local irritation, and with great asserted benefit, in *chronic syphilis.* Hill (*J. A. M. A.,* 1923, lxxx, 1365), however, was unable to observe any curative effect in experimental syphilis in rabbits. Chaleix (*Journ. de Méd. de Paris,* March, 1900) reports death from the use of a vaginal injection containing fourteen grains of mercuric cyanide. *Dose,* internally, from one-sixteenth to one-eighth of a grain (0.004–0.008 Gm.).

Mercuric Lactate. *Hydrargyri Lacticum.* $(C_3H_5O_3)_2Hg$.—It forms a white crystalline powder, soluble in water. This preparation has been used hypodermically in *dose* of one-sixth grain (0.010 Gm.) a day. Bouveyron (*S. M.,* 1905, p. 30) recommends that in cases of *syphilitic* lesions in the mouth, tablets of *mercury lactate* be allowed to dissolve slowly on the tongue.

Mercuric Oxycyanide. *N. N. R.* 1924. *Hydrargyri Oxycyanidum. Hydrargyri Oxycyanatum.* $HgO.Hg(CN)_2$.—This basic cyanide of mercury occurs as a white crystalline powder, soluble in 17 parts of water and turning litmus paper blue. The commercial preparations are frequently contaminated with the neutral cyanide of mercury. It has been brought forward as a substitute for mercuric chloride, both as a disinfectant and in the treatment of *syphilis.* The advantage is claimed for it as a germicide that it does not have an injurious effect upon steel instruments. Although Lehmann claimed that its germicidal power was equal to that of the bichloride, more recent experiments throw grave doubt upon this conclusion. Kruger, for example (*Desinfektion,* 1910, p. 456), reached the conclusion that its germicidal power was inferior to that of phenol. It is used in *syphilis* for hypodermic injection in the same doses as corrosive sublimate. Colombino (*G. Osp.,* 1917, xxxviii, 499) has irrigated the urethra with a 1 to 1000 solution for the abortion of *gonorrhea.*

Mercuric Pyroborate.—*Hydrargyri Pyroboras,* HgB_4O_7, is an amorphous, brown, insoluble powder, which has been commended by V. Tokayer (*Ph. Post,* 1892) as a local application in the treatment of specific and other ulcerations.

Mercuric Salicylarsinate.—*Hydrargyri Salicylarsinas. Enesol.*—By the interaction of molecular quantities of basic mercuric salicylate on methylarsenous acid, a white amorphous substance is formed which is difficultly soluble in water. The solution gives no reaction with hydrogen sulphide or with potassium iodide and may be sterilized without decomposition. The composition of the salt is mercury, 38.46 per cent., and arsenic, 14.4 per cent., with salicylic acid. Enesol is intended for subcutaneous injection in the treatment of *syphilis.* It is marketed in the form of a 3 per cent. solution.

The *dose* of the salt is from one-fourth to one grain (0.015–0.06 Gm.).

Mercuric Sozoiodolate. *Hydrargyrum Sozojodolicum.* $HgC_6H_2I_2OSO_3$.—This compound is a lemon-yellow powder, scarcely soluble in water, but more so in solution of sodium chloride. This preparation, which is said to contain 31 per cent. of mercury and 38 per cent. of iodine, has been especially recommended by Witthauer (*M. M. W.*, Aug., 1892) in the treatment of *syphilitic ulcerations, enlarged glands*, and *skin diseases*, in the form of a 1 per cent. ointment. The 1 per cent. solution is also used by Genzmer, as an injection into diseased joints, etc.

Mercuric Subsulphate, Yellow. *Hydrargyri Subsulphas Flavus. U. S.* 1890. *Mercuric Oxysulphate. Yellow Mercuric Subsulphate. Basic Mercuric Sulphate. Turpeth Mineral.* $Hg(HgO)_2SO_4$=729.87. *Hydrargyri Sulphas Flava. U. S.* 1870. *Hydrargyri Subsulphas.*

When normal mercuric sulphate is thrown into boiling or even warm water it is instantly decomposed, and an insoluble salt is precipitated, which is yellow mercuric subsulphate. Its composition is $Hg(HgO)_2SO_4$.

Yellow mercuric sulphate is a heavy, lemon-yellow powder, odorless and almost tasteless; permanent in the air. Soluble in about 2000 parts of water at 15° C., and in 600 parts of boiling water; insoluble in alcohol; readily soluble in nitric or hydrochloric acid. When heated, the salt turns red, becoming yellow again on cooling. At a red heat it is volatilized, evolving vapors of mercury and of sulphur dioxide, and leaving no residue. It was originally called *turpeth mineral*, from its resemblance in color to the root of *Ipomœa Turpethum*.

Yellow mercuric subsulphate is capable of acting as a mercurial and producing ptyalism. It is, however, in full dose violently emetic, and has been chiefly used in true *croup*. It is a dangerous remedy, especially with young children, several cases having been reported in which, failing to cause vomiting, it has produced death preceded by symptoms similar to those of corrosive sublimate poisoning. (See *M. News*, xliii, 1883; also, *London Med. Gaz.*, 1847.) Emetic *dose* for a child two years old, two or three grains (0.13–0.2 Gm.); for adult, three to five grains (0.2–0.32 Gm.), repeated in fifteen minutes if it does not operate. Alterative *dose*, one-fourth to half a grain (0.016–0.032 Gm.).

Mercuric Succinimide. *Hydrargyri Succinimidum. Hydrargol. N. N. R.* 1924. *Mercury Imidosuccinate.* $Hg[(CH_2.CO)_2N.]_2$.—This drug may be formed by heating together succinic acid, carbonic anhydride, and ammonia, which combine with mercuric oxide to form a compound which occurs as a white crystalline powder soluble in about 20 parts of water. This solution remains quite unchanged when kept. According to Vollert the solution of one and three-tenths grammes of this salt in one hundred of water is free from irritant properties, and when used hypodermically produces no disagreeable local or even secondary symptoms. (*Th. M.*, 1888.)

It was used by B. L. Wright with asserted extraordinary results in the treatment of *pulmonary tuberculosis*. Hartz (*J. A. M. A.*, 1911, lv, p. 915) and others were unable to see any beneficial effect from the drug in phthisical patients, except in those who were syphilitic. The *dose* employed was one-fifth of a grain (0.012 Gm.) injected intramuscularly every other day.

Mercuric Sulphate. *Hydrargyri Sulphas. Normal Mercuric Sulphate. Mercury Bisulphate. Sulfate Mercurique*, Fr. *Mercurisulfat*, G. $HgSO_4$ = 296.67.—Made by heating together 18 parts of mercury, 10 parts of concentrated sulphuric acid, 3 parts of water and 4 parts of 25 per cent. nitric acid, in a flask, on a sand bath, until reddish vapors cease to be given off, then drying with the aid of heat, in an open dish, constantly stirring. It is a heavy white crystalline powder, used in making turpeth mineral, and mercuric and mercurous chlorides. It has no use in medicine.

Mercuric Sulphide. *U. S.* 1880. *Hydrargyri Sulphidum Rubrum. Red Sulphide of Mercury. Cinnabar.* HgS=232.67.—This preparation, which was formerly official both in the United States and British Pharmacopœias, has been dropped from each. For process of making mercuric sulphide see *U. S. D.*, 19th ed., p. 1566.

Cinnabar is seldom prepared on a small scale, being made in large quantities for the purposes of the arts. Until within a few years it was nearly all manufactured in Europe, but it is now made to an enormous extent in this country. In Holland, where it is largely manufactured, the sulphur is melted in a cast iron vessel, and the mercury is added in a divided state, by causing it to pass through chamois leather. As soon as the combination has taken place, the iron vessel is surmounted by another, into which the cinnabar is sublimed. In the United States, Martin's method, consisting of the agitation together of quicksilver, sulphur, and an alkaline sulphide, appears to have the preference. Another process for its manufacture in the wet way very largely employed is Brunner's. (Wagner's *Chem. Tech.*, 13th ed., 1889, 552.)

Properties.—"Brilliant, dark red, crystalline masses, or a fine, bright scarlet powder, permanent in the air, odorless and tasteless, insoluble in water, alcohol, nitric or hydrochloric acid, or in dilute solutions of alkalies. It is dissolved by nitrohydrochloric acid with separation of sulphur. When heated, the salt becomes brown and then black, but, on cooling, it reassumes its red color. At a higher temperature it takes fire, burns with a bluish flame, emitting the odor of burning sulphur, and is finally volatilized without residue." *U. S.*, 1880. (For tests for purity, see *U. S. D.*, 19th ed., p. 1567.) In closed vessels at a red heat it sublimes without decomposition, and condenses in a mass, composed of a multitude of small needles. When duly levigated, it furnishes a brilliant red powder, which is the paint called *vermilion*. The same compound occurs native, being the sole ore—cinnabar—from which mercury is extracted. The preparation, if purchased in powder, should be carefully examined, as, in that state, it is sometimes adulterated with red lead, dragon's blood, or chalk. If red lead be present, acetic acid digested with it will yield a yellow precipitate (lead iodide) with potassium iodide. Dragon's blood may be detected by alcohol, which will take up the coloring matter of that substance, if present, and, if chalk be mixed with it effervescence will be caused on the addition of an acid.

Cinnabar is employed in medicine by fumigation, in *syphilitic affections*, when it is desired to obtain an immediate mercurial impression. Half a drachm may be thrown on a red-hot iron, in a close apartment, and fumes inhaled as they arise. These consist of sulphurous acid gas and mercurial vapor, the former of which must prove highly irritating to the patient's lungs. A better substance for mercurial fumigation is black mercurous oxide. It is also employed in the form of an ointment by Lassar (*Med. Klin.*, 1905, No. 3, 54), using red mercuric sulphide 1 Gm., sublimed sulphur 24 Gm., petrolatum 100 Gm., and oil of bergamot 30 drops. It is recommended in the treatment of *herpes tonsurans*.

Mercuric Sulphocyanate. *Hydrargyri Sulphocyanas.* $Hg(CNS)_2$.—This substance, formerly called *sulphocyanide of mercury*, is produced by mixing diluted solutions of mercurous nitrate and potassium sulphocyanate. The white precipitate which falls, after drying, swells up suddenly when ignited, giving off nitrogen, carbon disulphide, and poisonous vapor of mercury, leaving a voluminous gray residue, *mellon*, C_9H_{13}. The salt is used in the preparation of the toy, *Pharaoh's serpents*.

Mercuric Thymolnitrate. *Hydrargyri Thymolnitras.*—This salt, $(C_{10}H_{13}O)Hg.HgNO_3$, and *mercuric thymolsulphate* $[(C_{10}H_{13}O)Hg.Hg]_2SO_4$, have been used with asserted benefit in *syphilis*, in hypodermic *doses* of from one-twelfth to one-sixth of a grain (0.005–0.010 Gm.). (See *Merck's Jahresbericht*, 1891, 1892; also *W. K. W.*, March, 1892.) Besides these preparations *mercuric naphtholate*, a lemon-yellow powder, containing 30.8 per cent. of mercury, has been put upon the market; also under the name of *hydrargyrol*, *mercury paraphenylthionate* $(C_6H_4.OH.SO_3)_2Hg$, has been suggested as an antiseptic, but in proportion to its cost is probably of no practical value.

Mercuric Tribromphenol Acetate. *Hydrargyri Tribromphenol Acetas.*—A yellowish powder insoluble in water, containing 30 per cent. of mercury. It is employed as an antiseptic and antisyphilitic, best administered hypodermically in a white oil suspension containing about 25 per cent. of the salt. *Dose*, two grains (0.13 Gm.).

Mercuric and Zinc Cyanide. *Hydrargyri et Zinci Cyanidum.*—It is stated by Dunstan to be a true chemical compound, with the formula $Zn_4Hg(CN)_{10}$, but other authorities contradict this statement. It is a white powder, entirely insoluble in water. This substance has been very highly recommended by Lister as an antiseptic dressing, and is believed by him to be practically free from irritating or poisonous properties.

Mercurochrome. *Mercurochrome*-220 *Soluble. Mercuranine. N. N. R.* 1924.—The di-sodium salt of 2:7-dibromo-4-hydroxymercurifluorescein, containing from 23 to 24 per cent. of mercury.

This germicide was introduced by Young, White and Swartz (*J. A. M. A.*, 1919, lxxiii, 1483). The idea that led to its synthesis was that the combination of a stain with a potent germicide would carry the latter deeply into the tissues and thus reach bacteria which might have penetrated into the deeper layers of the mucous membrane. The compound that they called mercurochrome-220 is a combination of dibromfluorescein with mercury. Occurs as iridescent, green scales, slightly hygroscopic, readily soluble in water forming bright red solutions. Acids cause a precipitate. The original dye is an acid but is usually used in the form of the sodium salt. It is not precipitated by proteins nor by the normal acidity of the urine. In the strengths ordinarily used it is almost non-irritant.

Mercurochrome is a powerful germicide much less irritating than the chloride. Swartz and Davis (*J. A. M. A.*, 1921, lxxvi, p. 844) find that solutions as low as 1 in 4000 kill gonococci in five minutes, although it was less efficient against the *Bacillus coli*. Originally introduced as a urinary antiseptic, it has been extensively used in the treatment of *urethritis* and *cystitis* usually in strengths of about one per cent. It has also been employed as a general surgical disinfectant. Clapp and Martin (*J. A. M. A.*, 1920, lxxiv, 1224) have used it with favorable results in the treatment of *ophthalmia neonatorum*. They wash out the eyes with a 2 per cent. solution; this causes some burning sensation which, however, is only temporary. Gray and Meyer (*J. Inf. D.*, 1921, xxviii, 321) used it for the disinfection of the throat of *diphtheria* carriers with 98 per cent. of cures. It has also been used as a mouth wash in *gingivitis* and *pyorrhea alveolaris*.

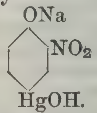
Swartz and Davis find that the solutions of mercurochrome, although undergoing no apparent change, become greatly weakened in their germicidal action on standing.

In 1924 Young and Hill (*J. A. M. A.*, lxxxii, 669) found by animal experimentation that the blood could be rendered bacterio-static by the intravenous injection of mercurochrome and reported a number of cases including general *septicemia, pyelitis, local abscesses*, etc., in which the intravenous injection was followed by prompt alleviation. The doses employed were from 3 to 5 milligrammes per kilo of body weight (approximately one-fiftieth to one-thirtieth of a grain per pound) usually in the form of a one per cent. solution.

Brill and Myers (*J. A. M. A.*, 1925, lxxxiv, p. 879) found, however, that 1 to 10,000 of mercurochrome in human blood did not prevent the growth of either streptococci or staphylococci, and when intravenously injected in cases of bacteremia had no apparent effect on the bacterial count of the blood nor the progress of the disease. Gatch, Trusler and Owen (*J. A. M. A.*, 1925, lxxxv, 894) find that it may exert a bacterio-static, though not a germicidal, effect in the blood and may in some cases be beneficial but that in large doses it is liable to do more harm than good.

One objection to the use of mercurochrome as a general surgical disinfectant is its vigorous staining qualities. It is said that the stains produced on the skin may be removed by the use of a 2 per cent. solution of potassium permanganate followed by 5 per cent. oxalic acid or by the use of solutions of the hypochlorites such as Dakin's Solution.

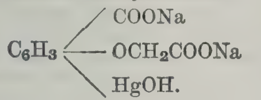
Mercurophen. *Sodium oxymercury-orthonitro phenolate.* Probably



This is an odorless, brick-red powder, sparingly soluble in water and freely soluble in hot water and yielding deep amber-colored solutions. It represents about 53 per cent. of mercury.

Mercurophen has been brought forward by Schamberg, Kolmer and Raiziss (*J. Inf. Dis.*, 1919, xxiv, p. 547) as a powerful disinfectant. They find that in strengths of from 1 in 400,000 to 1 in 2,000,000 it inhibits the growth of various bacteria; that its germicidal power is higher than that of mercuric chloride, especially in the presence of albumins. Moreover, it is much less irritant than the bichloride; a 1 to 1000 solution instilled in the rabbit's eye caused no visible effect and a 1 per cent. solution only slight congestion. They state that its toxicity is less than half that of corrosive sublimate and that it does not tarnish steel nor precipitate protein in germicidal strengths. Shivers (*J. of Urology*, 1922, viii, 35) has used it in *gonorrhea* in strengths of from 1 in 4000 to 1 in 10,000.

Mercurosal. *N. N. R.* 1924.—It is claimed to be di-sodium-mercuri-salicyl-acetate



$$\mathrm{C_6H_3}\begin{cases}\mathrm{COONa} \\ \mathrm{OCH_2COONa} \\ \mathrm{HgOH.}\end{cases}$$

This occurs as a pale yellow, almost white, amorphous powder, freely soluble in water and representing about 44 per cent. of metallic mercury. The solutions, if protected from light, remain unchanged for a limited time.

Mercurosal is intended for intramuscular or intravenous injection in the treatment of *syphilis.* The claims made for it are that it is free from corrosive property, that it does not precipitate blood serum and that it is only one-seventh as toxic as the mercuric chloride although it contains four-sevenths as much mercury. Smith (*Illinois Med. Jour.*, May, 1920), Marchand (*New Orleans Med. and Surg. Jour.*, May, 1921) and others have reported favorably on its clinical effects. It is marketed in sealed ampules of two sizes, containing 0.05 and 0.1 Gm. respectively (three-fourth and one and one-half grain).

Mercurous Acetate. *Hydrargyri Acetas. Mercury Acetate.* $Hg_2(C_2H_3O_2)_2$.—White, scaly crystals, soluble in about 330 parts of water, insoluble in alcohol and ether. It should be kept dry and away from light as it is decomposed, by boiling water and exposure, into mercury and mercuric acetate. Used internally in *doses* of from one-fifth to one grain (0.012–0.065 Gm.) for *syphilis.*

Mercurous Bromide.—*Hydrargyri Bromidum,* Hg_2Br_2, is formed by adding potassium bromide to mercurous nitrate. It falls as a white, curdy precipitate.

Mercurous Iodobenzolparasulphonate. *Anogon.*—It is a yellow, crystalline powder insoluble in all the ordinary solvents, representing 48.5 per cent. of mercury and 30.7 per cent. of iodine. It is used in suspension in olive oil, and as an intramuscular injection in the treatment of *syphilis.* The *dose* is fifteen minims (0.9 cc.) of a 10 per cent. suspension.

Mercurous Sulphide. *Hydrargyri Sulphidum Nigrum. Black Sulphide of Mercury. Ethiops Mineral.* Hg_2S.—This now disused remedy was prepared as follows: "Take of Mercury, Sulphur, each, *a pound.* Rub them together till all the globules disappear." *U. S.*, 1850 For properties, see *U. S. D.*, 14th ed., 1259.

Mercurous Tannate. *Hydrargyri Tannas.* $Hg_2.3(C_{14}H_9O_9).OH$. *Hydrargotin.*—*Mercurous tannate,* which was first brought forward by Lustgarten (*N. Y. M. J.*, March, 1892), has received some favor at the hands of syphilographers, and is official in the Austrian Pharmacopœia (1906), under the name of *Hydrargyrum tannicum oxydulatum.* It is declared that it has the especial advantage of being unabsorbed in the stomach, but decomposed by the alkaline juices of the duodenum, in such a way as to yield very minute globules of metallic mercury. It may be prepared either by precipitating concentrated solution of tannic acid and mercurous nitrate or by rubbing together tannic acid and mercurous nitrate. According to Lustgarten, the first process yields the better preparation. It is asserted that it does not irritate the alimentary canal. In *syphilis,* three grains (0.2 Gm.) may be given to the adult daily, increasing to five grains (0.32 Gm.) or more.

Mercury Atoxylate. *Mercury Paraminophenylarsenate. Atoxyl Mercury. Aspirochyl. Asiphyl.* $C_{12}H_{14}O_6N_2As_2Hg$.—This occurs as a white powder insoluble in water, and represents 31.8 per cent. of mercury. It has been introduced as an antisyphilitic with the idea that it would combine the effects of its two constituents. Manteufel (*Med. Klin.*, 1908, p. 1651) found it to be actively destructive to *spirilli, spirochete* and *trypanosomes,* and obtained favorable clinical results in *syphilis.* Bergrath (*D. M. W.*, 1910), however, reached the conclusion that it had no advantage over other forms of mercury. It is administered by intramuscular injection in the form of a 10 per cent. emulsion in olive oil. Of this emulsion from eight to fifteen minims (0.5–1.0 cc.) may be injected once or twice a week. It is also used in the form of an ointment (1 in 20).

Mercury Resorcinol Acetate. *Resorcinol Mercury Acetate.*—A yellow, crystalline powder containing 69 per cent. mercury. It is soluble in strongly alkaline solutions and in hydrochloric acid, but insoluble in alcohol and water. It is used as an antisyphilitic hypodermically in liquid paraffin and melted lanolin solution. Three minims (0.2 cc.) of a solution of eighty-five grains (5.6 Gm.) of the salt in the same amount of paraffin oil and thirty grains (2.0 Gm.) of anhydrous lanolin is injected twice weekly, the mixture being warmed to 25° C. before being used.

Mergal. *N. N. R.* 1924.—Under this name there has been introduced into medicine a mixture which is asserted to contain one part of *mercuric cholate,* $Hg(C_{24}H_{39}O_5)_2$, with two parts of albumin tannate. It occurs as a yellowish-white powder, practically insoluble in water, but dissolving in alkaline solutions. Mergal has been highly lauded by a number of authors as a satisfactory means of exhibiting mercury in the treatment of *syphilis.* According to Barges (*Fort. Med.*, 1907, No. 27) mercury appears in the urine within four hours after its exhibition by the mouth, and elimination —which is partially through the kidneys and partially through the intestinal glands—goes on with great regularity, so that the prolonged use of the remedy is less liable to lead to undesirable results than with the ordinary form of mercury. It contains approximately 4.4 per cent. of mercury and is dispensed in capsules, which contain 0.05 Gm. each (three-quarters of a grain) of mercuric cholate and one and a half grains (0.096 Gm.) of albumin tannate. Of these from five to ten may be given daily.

Meroxyl. *N. N. R.* 1925.—A mixture containing approximately 50 per cent. of the sodium salt of 2,4-dihydroxy-3,5-dihydroxy-mercuribenzophenone-2-sulphonic acid, with foreign matter consisting of ammonium-2,4-dihydroxy-benzophenone-2-sulphonate, sodium acetate and water. It represents about 27 per cent. of mercury.

It has been brought forward as a local germicide by Young, White, Hill and Davis (*Surgery, Gynecology and Obstetrics,* 1923, xxxvi, 508. It is used for wet dressings of wounds, and also for irrigation of wounds and infected bladders.

Meroxyl occurs as a pinkish powder easily soluble in hot water up to 10 per cent. Solutions of 2.5 per cent., or stronger, gel or form a deposit on cooling. The color of the solution varies with concentration; a 0.5 per cent. solution has a brownish pink color with greenish fluorescence, the color becoming browner in more concentrated solutions.

It is used in strengths of from 0.1 to 0.5 per cent.

Mesembryanthemum. *Mesembryanthemum crystallinum* L. *Ice Plant. Diamond Fig.*—A biennial plant of the Fam. *Aizoaceæ,* a native of the south of Europe, now distributed to the Canary Islands, Southern Africa, Australia and California. The stem and under surface of the leaves are covered with crystalline drops, which give the plant the appearance of being coated with ice. H. Mangon obtained as much as 43 per cent. of salts of potassium and sodium from the dried leaves. (*A. J. P.*, 1883, 370.) The herb is without odor, and has a saline, somewhat nauseous taste. It is considered demulcent, diuretic, and has been used in *inflammations* of the *pulmonic* and *genito-urinary* mucous membrane.

Holmes (*P. J.*, 1918, ci, 317) grew some seeds which were found in a Moroccan soap substitute called *ghassoul,* and found them to yield the *M. crystallinum* L. and the *M. nodiflorum* L. The cleansing power is due to the presence of saponin.

In the *Mesembryanthemum expansum,* Hartwich and Zwicky (*Ap. Ztg.*, 1914, xxix, p. 925) found an alkaloid *mesembrine,* $C_{16}H_{19}O_4N$, with a cocaine-like action.

Mesenna. *Musenna. Bisenna. Musena. Moucéna,* Fr. *Musennarinde,* G.—Under these different names has been brought into notice, as a powerful *tænifuge,* the bark of an Abyssinian tree, *Albizzia anthelmintica* Brongn. (Fam. *Leguminosæ*). The bark is in flat pieces from five to ten inches long, smooth, slightly fissured, of a rusty gray color exteriorly, and pale yellow and fibrous within. It consists of four layers, one of which contains very large cells, with thick coats and is supposed to be the active part. E. Caventou and Legendre found in the bark no alkaloid, but a peculiar, acid, acrid, resinous substance. The *musennin* of Theil is probably the same, although not as yet in a pure state. The Abyssinians employ the powdered bark, in the *dose* of about two ounces, suspended in water or other liquid, or mixed with flour in the form of bread, or made into a confection with honey, butter, etc. It is taken in the morning, three or four hours before breakfast, and no other precautions are used. It produces no pain nor any disturbance of the functions, not even purging actively. Fragments of the worm are voided the same evening, and the greater portion of it the next day.

Mesotan. *Salmester. Salicylic Acid Methyloxymethylester. Ericin. N. N. R.* 1924. $C_6H_4OHCOO(CH_2OCH_3)$.—This preparation is a yellow, clear fluid with a peculiar odor, miscible in all proportions with ordinary oils, sp. gr., 1.2, boiling point, 162° C. It has been brought forward as a local application in all forms of *rheumatism.* In from half an hour to an hour after its local application the presence of salicylic acid can be demonstrated in the urine. When applied pure to the skin and confined by waxed paper or other appropriate dressing it produces redness and sometimes pronounced burning pains, so that it should be diluted with olive oil, castor oil, petrolatum or liquid petrolatum. Even when diluted, mesotan may produce eczematous, urticarial, or other eruption upon the skin, requiring its removal or further dilution. From one and a half to two and a half fluidrachms (5.5–9.3 cc.) of an oily solution, containing 20 to 50 per cent. of mesotan, may be applied daily to the affected part.

Mesothorium.—This is the name which has been applied to the first product of the disintegration of thorium. It appears to give off, like radium, three types of rays and an emanation. It has been used by Voigts (*M. M. W.*, 1913, lx, 1186) in *uterine hemorrhages.* It is probable that mesothorium has therapeutic properties very similar to those of radium. See also Emsmann (*B. K. W.*, 1911, p. 2108), and *P. J.*, 1913, 608. Mesothorium is obtained from the monazite sand in Brazil.

Mespilus Germanica L. *Medlar.* (Fam. *Rosaceæ.*)—The fruit of this tree has been recommended by Mercier (*A. G. M.*, 1907) in the treatment of *chronic enteritis* and *colitis.* It may be either eaten fresh or preserved. The method he employed was to put the patient on a diet consisting of two quarts of milk and eight ounces of medlar daily, no other food being allowed.

Metaferrin.—This is an iron albumen combination representing 10 per cent. of iron. It is a brownish, odorless powder, insoluble in water and dilute acids, but soluble in alkalies. It is supposed to pass through the stomach unchanged, and be absorbed from the intestinal tract, and hence not to affect gastric digestion. It is used in *anemia.* The *dose* is four grains (0.26 Gm.) three times a day generally in tablet form. There is also a "liquid form of metaferrin," *metaferrose,* the *dose* of which is one tablespoonful.

Metaphen. Bisacetoxymercuri-4-nitro-2-cresol. $(CH_3COOHg)_2:(C_6H.CH_3.OH.NO_2)$. *N. N. R.* 1924.—This is a yellow, odorless, tasteless powder almost insoluble in water, but soluble in the presence of sodium hydroxide; it contains from 58 to 60 per cent. of mercury. According to Raiziss and Severac (*J. Lab. Clin. M.*, 1923, ix) it is a more powerful germicide than corrosive sublimate and is only half as toxic. Moreover it does not precipitate protein and is practically non-irritant to mucous membranes.

It is stated to be without deleterious influence on metallic instruments. It has been brought forward as a surgical disinfectant and as a local application in cases of gonorrheal *urethritis.* For disinfection of the skin instruments, etc., solutions of 1 in 1000, made with the aid of sodium hydroxide, may be employed, while for urethral irrigation solutions of from 1 in 5000 to 1 in 10,000 are recommended.

Methacetin. *Para-acetanisidine. Para-oxymethylacetanilide.* $C_6H_4(OCH_3).NHC_2H_3O$.—This differs from acetanilide in having an atom of the nucleus replaced by the oxymethyl group (OCH_3) or from acetphenetidin by having oxymethyl instead of oxyethyl as a replacing group. It forms lustrous crystals free from color, odorless, melting at 127° C., and distilling at higher temperatures unchanged. It is scarcely soluble in cold water, readily soluble in hot water, soluble in alcohol, acetone, chloroform, glycerin, and fatty oils. When triturated with chloral, bromal or phenol it liquefies and with resorcin it forms a mass. Its color and identity reactions are similar to those of phenacetin from which substance it may be distinguished, however, by the fact that when it is heated with a quantity of water insufficient for solution it melts to an oily liquid, while phenacetin does not. According to F. Manhnert, when given in toxic dose to rabbits, it causes convulsions and death through its action on the central nervous system, and is germicidal in 1 per cent.

solution. Methacetin appears to be a powerful antipyretic, producing in fever a very marked fall of temperature, with a slow afterrise; this effect being accompanied by a violent sweating, which especially in *phthisis* and allied diseases, greatly interferes with the practical use of the drug. It has also been much used in *acute rheumatism,* but is not as effective as the salicylates. As an analgesic, in *ataxic* and *neuralgic pains,* it appears to be distinctly inferior to phenacetin and antipyrine. No eruption from it has been noticed. During its administration the urine responds to Trommer's test, but does not contain sugar, nor is there hemoglobinuria. *Dose,* for adults, eight grains (0.5 Gm.).

Methanol. *Methyl Alcohol. Methylic Alcohol. Carbinol. Spiritus Pyroxylicus Rectificatus. Br.* 1864. *Pyroligneous Spirit. Pyroxylic Spirit. Wood Spirit. Wood Alcohol. Wood Naphtha. Alcool méthylique, Alcool formique, Alcool de Bois, Esprit de Bois, Esprit pyroligneux,* Fr. *Holzgeist,* G. CH_3OH.—Methyl alcohol was discovered in 1812 by Taylor. When wood is subjected to destructive distillation, there is formed, besides acetic acid, tar, and other products (see *Creosotum,* Part I), about 1 per cent. of an inflammable volatile liquid, which, when separated and purified, constitutes methyl alcohol. The crude liquor, derived from the wood, separates on standing into two liquids; the heavier containing the tarry matters, and the lighter consisting of water, acetic acid, methanol, etc. The lighter liquid is saturated with lime, and subjected to distillation, whereby the impure methyl alcohol first comes over, mixed, however, with various compounds, among which are aldehyde and pyroacetic spirit (acetone). This, after having been redistilled and deprived of water by repeated rectifications from lime, forms the methyl alcohol of commerce. The commercial spirit may be purified by adding to it as much calcium chloride as it can dissolve, and allowing the mixture to stand for a few days. The methanol unites with the calcium chloride, and the compound formed is subjected to distillation to separate certain contaminating substances, which distil over. Finally, the methanol is separated from the calcium chloride by the addition of water and a new distillation, and from water by rectification from dry lime. Methyl alcohol, like the other monatomic alcohols, can also be formed synthetically in a variety of ways—from marsh gas, from formic acid, and from formaldehyde. Pure anhydrous methanol is a mobile, colorless liquid, possessing a hot, pungent taste, and a peculiar odor. It mixes in all proportions with water, alcohol, and ether. It burns like alcohol, but with a less luminous flame. Its sp. gr. as a liquid is 0.8021 at 15.5° C. Its vapor is irritating to the eyes. It boils at 65° C. As a solvent it resembles alcohol, most substances soluble in that menstruum being likewise soluble in it.

It is desirable to be able to distinguish the presence of methanol in ethyl alcohol, and in preparations which may have been made from the methylated instead of the pure spirit. For this purpose the official test is the best which has been proposed. See test for methyl alcohol under *Alcohol* (Part I); see also *Ph. Centralh.,* 1913, No. 29.

Columbian spirit is simply a brand of wood alcohol of a high quality, free from empyreumatic odor and with only a slight trace of acetone as impurity. *Colonial spirit* is also a purified methyl alcohol.

Methylated spirit, much used in England, contains nine parts of ethyl alcohol to one part of methanol.

Crude methyl alcohol is very largely used in the arts as a solvent, especially in the manufacture of varnish and other resinous solutions. It is also considerably employed as a source of heat, but the ordinary varieties of the spirit during burning give off an offensive odor.

Methanol is capable of producing an intoxication similar to that caused by ethyl alcohol, but distinct in the slowness of the onset and the extraordinary duration of the symptoms, which may last from three to four days after the comparatively moderate dose of the drug. The symptoms which have been observed in methyl alcohol poisoning are marked fall of the body temperature, convulsions, sometimes of a tetanic character, at others of a choreic type, vomiting, dilatation of the pupil, frequently nystagmus. The reflexes at first are increased, but after a period of a day or two loss of sensation and also of reflex power may occur. Quite characteristic of the poisoning is the loss of vision which begins generally within twenty-four hours and may progress to complete blindness. *Per se* methyl alcohol is less toxic than ethyl alcohol and the severity of the symptoms which it causes indicates that the effects must be due to some decomposition product, and the present evidence is strong that this educt is formic acid. Krol (*A. E. P. P.,* 1913, lxxii) has called attention to the similarity of the symptoms of wood alcohol poisoning with those of acidosis. Harron and Benedict (*J. A. M. A.,* 1920, lxxii, p. 25) reports a case of methanol poison in which chemical examination of the blood showed a great diminution in the alkali reserve and the presence of considerable amount of both lactic and formic acid in the urine, as well as acetone bodies; the administration of large quantities of alkali caused, in this case, immediate relief from the acute symptoms, although the patient was left with permanent impairment of vision. Both Reid Hunt and Schmiedeberg have demonstrated that methanol is oxidized in the body to formic acid. Autenrieth (*M. M. W.,* Aug. 1, 1919) has recovered from the urine a quantity of formic acid equivalent to more than 5 per cent. of the ingested spirit.

The amblyopia is due to an inflammation of the optic nerve with eventually, in severe cases, complete optic atrophy. In 90 per cent. of cases there is permanent impairment of vision. It is probable that this predilection for the optic nerve is part of the general tendency towards the nerve trunks for Jelliffe (*M. News,* 1905, lxxvi, p. 387) reports a case of multiple neuritis. For review of the literature on this subject, see Holloway, *N. Y. M. J.,* 1911, xciii, p. 1030.

Many of the cases of poisoning have been due to the innocent use of liquor, or even essence of ginger, which have contained more or less wood alcohol. The use of this substance for the purpose of denaturing grain alcohol, although at present officially permitted by the U. S. Internal Revenue Service, is a dangerous practice. It should be noted that it is not necessary for this poison to be swallowed in order to produce its characteristic effects. A number of cases of permanent blindness have followed the inhalation of its fumes by workmen using varnish containing it or from various dyes in which it is a solvent. Several cases have also been reported in which the external application of methyl alcohol, either as a liniment or accidentally, has led to serious poisoning, and it is therefore highly probable that enough of it may be absorbed through the skin to exercise its injurious effects. (See case reported by Woods, *J. A. M. A.*, 1913, lx, p. 1762.)

In the treatment of wood alcohol poisoning the first step is to thoroughly empty the stomach, which is best accomplished by means of the stomach tube, and the intestines, with a saline purge. The probability that the toxic symptoms are due to acidosis strongly suggests the use of alkalies to combat subsequent symptoms and Isaacs (*J. A. M. A.*, April 10, 1920) has reported favorable results from the use of 45 grains (3 Gm.) of sodium bicarbonate every two hours, or in sufficient quantity to keep the urine alkaline. If the patient be comatose or the cyanosis very marked he recommends the administration of the alkali intravenously. Venesection is sometimes advisable. Haskell, Hillman and Gardner (*A. I. M.*, January, 1921), although they found an acidosis, were not greatly encouraged by the results of the alkaline treatment in experimental poisoning.

Methyl alcohol is a so dangerous remedy that its use for any medical or pharmaceutic purpose is unjustifiable and under no circumstance should it be employed by pharmacists as a menstruum or as a solvent for medicinal preparations of any kind.

Methyl Atropine.—Two salts are on the market, namely the bromide (*methyl-atropine-bromide* of *Mydriasine*), $C_{16}H_{20}O_3N(CH_3)_2Br$, and the nitrate (*methyl-atropine-nitrate* or *Eumydrin*), $C_{16}H_{20}O_3N(CH_3)_2NO_3$.

Atropine Methylbromide occurs as white crystals with a melting point between 222° to 223° C., freely soluble in either water or alcohol. *Atropine methyl nitrate* is a white, crystalline, odorless powder, soluble in both water and alcohol. Its solutions are permanent but have the incompatibilities of alkaloids in general.

Methyl-atropine closely resembles ordinary atropine in its effects on the system, but requires somewhat larger quantities to produce the same effect. As a mydriatic it is employed in strengths of from 1 to 4 per cent. The dilatation of the pupil comes on more promptly than after atropine and is of less duration. Hudovernig (*B. K. W.*, 1906) asserts that it has a marked analgesic action and is a useful remedy in various types of *headaches* and *neuralgia.* It has been found useful for many of the purposes in which atropine is employed especially for the control of *night sweats* and in the treatment of *gastric ulcer.* A spray containing 0.3 per cent. of methyl atropine bromide with 1 per cent. of anasthesin has been recommended as an inhalation for the relief of *asthma.* The dose of either salt is from one-sixtieth to one-twentieth grain (0.001–0.003 Gm.).

Methyl Chloride. *N. N. R.* 1924.—*Monochlormethane,* CH_3Cl, is obtained by the action of hydrochloric acid gas upon methyl alcohol, best in the presence of a little zinc chloride. It is a colorless gas, condensing to a liquid at –23° C., and is very soluble in alcohol, which dissolves thirty-five volumes of it, but is insoluble in water. On account of its extreme volatility, methyl chloride, when applied in the form of a spray, produces extreme cold and freezing of the part. It has been used in this way as a local anesthetic. At very low temperatures it forms with water a hydrate. According to Richet and Marcille (*S. M.*, 1902), methyl chloride acts upon the animal as an efficient anesthetic, which has practically no influence upon the circulation. Its usefulness seems to be limited by its failure to produce complete muscular relaxation. We know of no clinical reports upon its activity.

Methyl Iodide. *Iodomethane.* CH_3I. *Iodure de Methyl,* Fr. *Jodmethyl,* G.—This is a heavy, sweet-smelling liquid, boiling at 43° C., and has a sp. gr. of 2.23 at 15° C. In the cold it unites with water to form a crystalline hydrate, $CH_3I + H_2O$. It turns brown, gradually, on exposure to light. It is made by the action of dry hydrochloric acid gas upon a mixture of potassium iodide and anhydrous methyl alcohol.

R. Kirk (*L. L.*, Oct., 1885) commends *methyl iodide* as a vesicant, applied on lint under a watch glass, a drop or two of soda solution being added to neutralize the free iodine that may be present. It produces at once a tingling, burning, biting sensation, like pricking with a number of needle points. The maximum pain is reached in a few minutes, when the substance is to be removed. The blister produced is said to be as full of serum as that caused by cantharides.

Methyl Ether. $(CH_3)_2O$. *Methylic Ether. Methyl Oxide. Hydrate of Methylene. Ether méthylique, Oxyde de Méthyl,* Fr. *Methyläther, Holzäther Formäther,* G.—This substance was employed as an anesthetic by B. W. Richardson in 1867. He prepared it by mixing one part pure methyl alcohol with two of strong sulphuric acid, heating, collecting and washing repeatedly with potassium hydroxide solution the methyl ether which passes over. It is a gas even at low temperature. A saturated solution of the gas in ethyl oxide was at one time suggested as a surgical anesthetic under the name of *methyl-ethylic ether.*

Methylal. *Methylene Dimethyl Ester. Formal.* $CH_2(OCH_3)_2$.—This is made by distilling methyl alcohol with sulphuric acid in the presence of manganese dioxide, or by abstracting one molecule of water from a mixture of one molecule of formaldehyde and two of methyl alcohol. It is a limpid colorless liquid, of sp. gr. 0.855 at 17° C. and boils at 42° C. It is soluble in water, alcohol, ether, and fatty and ethereal oils. It was originally proposed as an anesthetic and hypnotic by B. W. Richardson in 1868. Richardson, Motrokhin, and Personali are in general accord as to its physiological action. It produces in man a sleep closely resembling the normal sleep; or, if the dose has been large enough, a profound coma in which reflex actions are suspended. Recovery is rapid on account of its rapid elimination. The arterial pressure is reduced, as is also, according to Motrokhin, the irritability of the cerebral cortex. Both Personali and Motrokhin found that it arrests the tetanic spasms produced by small doses of strychnine, although in Motrokhin's experiments, when large doses of strychnine were given, methylal seemed to accelerate rather than put off death. It has been employed as an hypnotic, and is said to be free from danger and unpleasant effects; but in most cases patients become so rapidly accustomed to it that its influence soon disappears, unless enormous doses are used. The *dose* is from one-half to one fluidrachm (1.9–3.75 cc.), given in emulsion.

Methylene Dichloride. *Methylene Chloride. Dichloro-methane. Bichloride of Methylene.* CH_2Cl_2.—It may be prepared by exposing to sunshine, in a glass globe, pure chlorine and gaseous methyl chloride. Methylene dichloride is a colorless liquid, of an odor resembling that of chloroform, of the sp. gr. 1.344, and the boiling point 40° C. The vapor is inflammable, burning with a brilliant flame, and yielding, as the result of combustion, carbon dioxide and hydrochloric acid. Methylene dichloride mixes readily with absolute ether, and, as the boiling points of the two approach nearly, they volatilize evenly and equably. It is neutral to test paper; an acid reaction in any specimen would be an evidence of the presence of hydrochloric acid, and should preclude its use. To prevent the generation of the acid, the liquid should be kept carefully secluded from the sunlight, and the addition of a small quantity of absolute alcohol is recommended.

Methylene dichloride was suggested by Richardson as a general anesthetic, the advantages of being quick and powerful. It enjoyed considerable popularity at one time but some years ago H. C. Wood examined a sample of methylene dichloride supplied by one of the most reputable English firms and found that it contained practically none of this compound and was largely chloroform. Gutzart, as the result of the examination of several German specimens, states that they are mixtures of alcohol, methylene dichloride and chloroform in varying proportions. Merck states that the product used by Richardson, which they call *methyl dichloride,* is really a mixture of one volume of methyl alcohol with three of chloroform.

As yet methylene dichloride cannot be regarded as a safe anesthetic. Even the mixture of methylene dichloride and absolute ether, which Richardson introduced under the name of *methylene ether* (*M. T. G.*, ii, 1872; i, 1873), has caused death. (*P. M. T.*, iii, 718; *M. T. G.*, July, 1873.) The methylene dichloride may be given internally in the *dose* of from ten to thirty minims (0.6–1.8 cc.), which may be dissolved in dilute spirit.

Metol. *Monomethylpara-amido-metacresol-sulphate.* $(C_6H_3[OH]CH_3[NH]CH_3)_2H_2SO_4$.—A white powder, soluble in water and extensively used as a developing agent in photography and in X-ray processes.

Micrampelis. *Micrampelis fabacea* (Naud.) Greene. (*Megarrhiza californica* Torr., *Echinocystis fabacea* Naud.) *Man Root. Big Root. Gerba marra.* (Fam. *Cucurbitaceæ.*)—J. P. Heaney has obtained a substance from this root of resinous character which he calls *megarrhizitin,* and another which he believes to be a glucoside and calls *megarrhizin.* It is said to be actively cathartic. (*A. J. P.*, 1876, 451.) A second glucoside was obtained by W. M. Young (*A. J. P.*, 1883, 195), to which the name of *megarrhin* was given. It resembles saponin, and possesses the property of dilating the pupil. Young also found two resins, one soluble in alcohol and the other soluble in ether.

Microcidin. *Betanaphthol Sodium.*—Under this name the varying compounds of *sodium naphtholate* with other naphtholates and phenates have been put upon the market, and used as surgical antiseptics in solution varying from three to five per cent. As a nasal or aural douche a 0.1 per cent. to 0.5 per cent. solution is recommended.

Micromeria. *Micromeria Chamissonis* (Benth.) Greene. *Yerba Buena.*—This sweet-scented labiate, which is popularly known as *yerba buena,* is a trailing perennial, indigenous to the Pacific Coast. Power and Salway have obtained besides 0.16 per cent. of a volatile oil with a mint-like odor, two new alcohols, which they named *micromol,* and *micromeritol,* and a phenol, *xanthomicrol.* (*J. Am. C. S.*, 1908, 251.) The fluidextract prepared from this plant has been used popularly as an emmenagogue. *Dose,* one-half to two fluidrachms (1.8–7.5 cc.).

Midrol. *Iodomethylate of Phenylpyrazolon.*—*Midrol* forms white, bitter and water soluble crystals. It is used as a mydriatic, in 5 to 10 per cent. strength. One drop of a 10 per cent. solution introduced into the conjunctiva causes at first contraction, then dilation, of the pupil which lasts about two hours.

Migrol. *Pyrocatechin-monoaceto-dimethylamidophenyldimethyl-pyrazolon.*—It forms colorless crystals of an intensely bitter taste, of slight acid reaction and soluble in water and alcohol. It is used in 0.5 gramme (8 grain) doses in *neuralgia* and *rheumatism.*

Miré.—This is a shrub found growing in Central Bolivia whose rhizome and roots, stems and leaves are used by the aborigines of that country as a muscular paralyzant and remedy for cutaneous parasites. H. W. Youngken investigated the gross and microscopic structure of the plant from material collected in 1921 by members of the Mulford Biological Exploration Party in Central Bolivia. He determined it to be a species of *Brunfelsia* belonging to the Fam. *Solanaceæ,* the structure of the stems and leaves of which bears a striking similarity to *Brunfelsia hydrangæformis* (Phol.) Benth. (See *Jour. A. Ph. A.*, 1925, p. 195.)

According to H. H. Rusby (*J. A. Ph. A.*, 1924, xiii. p. 101) the natives of the region in which this plant is found boil the drug to extract its active principle and claim the perspiration which follows the internal use of this drug is capable of killing cutaneous parasites, further that it paralyzes the voluntary muscles precisely like alcoholic intoxication.

T. S. Githens (*J. A. Ph. A.*, xiii, 102) states that miré causes paralysis of voluntary motion by its action on the spinal cord and that it stimulates the salivary and sweat mechanism as well as the peripheral motor apparatus.

Momordica. *Momordica Balsamina* L. *Balsam Apple. Balsamina.* (Fam. *Cucurbitaceæ.*)—An annual climbing East Indian plant, cultivated in our gardens for the sake of the ornamental fruit. The latter is ovate, attenuated towards each extremity, angular, warty, not unlike a cucumber in appearance, of a lively red or orange-yellow color, easily falling when touched, and spontaneously separating into several pieces. A liniment formed by infusing the fruit, deprived of its seeds, in olive or almond oil, is applied to *chapped hands, burns, piles, prolapsus ani,* etc.; and the mashed fruit is sometimes used as a poultice. According to Descourtilz, two or three drachms taken internally will kill a dog. An extract prepared from it is said to be useful in *dropsy. Dose,* six to fifteen grains (0.4–1.0 Gm.).

Monarda. *Monarda punctata* L. *Horsemint. Menthe de Cheval,* Fr. *Pferdeminze, G.*—This is an indigenous perennial or biennal labiate, growing in light gravelly or sandy soils from New York to Texas and west to Wisconsin. The whole herb is employed. It has an aromatic odor, and a warm, pungent, bitterish taste, and abounds in a volatile oil, which may be separated by distillation with water. Herman J. M. Schroeter (*A. J.*

P., 1888, 120) found the oil to consist of a hydrocarbon, $C_{10}H_{16}$ (56 per cent.), thymol, $C_{10}H_{14}O$ (25 per cent.), and higher oxygenated compounds, $C_{10}H_{18}O$. Kremers (*Ph. Rev.*, 1896, 223) examined the oil from authentic specimens and found it to yield from 56 to 61 per cent. of a phenol (thymol). Horsemint is stimulant and carminative, but is seldom used in regular practice. In the state of infusion it is occasionally employed as a domestic remedy for flatulent *colic* and sick stomach, and for other purposes to which the aromatic herbs are applied. *Monarda fistulosa* L., *wild bergamot*, an active diuretic (see *Proc. A. Ph. A.*, 1895, 256; 1896, 238), contains, according to J. W. Brandel and E. Kremers, *hydrothymoquinone, thymoquinone,* besides cymene, carvacrol and limonene. (*Ph. Rev.*, 19.) The oil of *Monarda citriodora* Cerv., or *prairie bergamot*, according to Brandel (*P. J.*, 1894, liii, 547), contains 65 per cent. of a phenol and 1.2 per cent. citral. See also *Midland Druggist*, 1910, 526, and a paper by Nellie Wakeman in the *Proc. A. Ph. A.*, 1910, 979. For the composition of monarda oils see *Ph. Archiv.*, 1899, 73.

Mon-Arsone.—This is di-sodium ethyl arsonate, hence related to sodium cacodylate and more nearly to arrhenal. It has been suggested as a substitute for arsphenamine in the treatment of *syphilis.* Nichols (*J. A. M. A.*, 1921, lxxvi, 1335) has found that while in rabbits it has some spirocheticide effect the dose required is large enough to kill the animal, *i.e., in* sub-lethal doses it has no value.

Monesia.—A South American vegetable extract, which is derived from the bark of *Pradosia latescens* Radlkofer. (Fam. *Sapotaceæ*), a tree of moderate size, growing in the forests near Rio Janeiro and elsewhere in Brazil. The bark, which has also entered commerce, is in pieces, some of which are three or six mm. thick, is very compact and heavy, of a deep brown or chocolate color, contrasting strongly with the grayish color of the epidermis when this remains, and of smooth fracture. The extract is of a dark brown almost black color, very brittle, the fracture neither very dull nor very shining, and of a taste at first sweet, then astringent, and ultimately acrid, the acridity being very persistent. It is entirely soluble in water. The bark contains glycyrrhizin and, according to Peckolt (*A. J. P.*, 1884, 626), a saponin, *monesin;* an acrid, amorphous body, *lucumin;* a peculiar tannin, *monesiatannic acid;* tartaric and citric acids, wax, etc. *Monesin*, $C_{32}H_{54}O_{18}$, was in transparent, yellowish scales, which were easily pulverized, forming a white powder. It was uncrystallizable, readily soluble in alcohol and water, to the latter of which it gave the property of frothing, and insoluble in ether. It was without odor, but had a slightly bitterish taste, followed by a decided and permanent acrimony in the posterior mouth and fauces. Monesia owes its activity probably to this principle and to tannic acid.

Monesia is stomachic and feebly astringent, and has been used with asserted advantage in *diarrhea, hemoptysis, menorrhagia, scrofula, scurvy,* also as a local remedy in *leucorrhea, ulcerations of the mouth and fauces* and *ulcers.* It is applied to ulcers either by being sprinkled in powder upon the surface or in the form of ointment made with one part of the extract and seven parts of simple ointment. The *dose* of the extract is from two to ten grains (0.13–0.65 Gm.), repeated every one to three hours. Monesin has been given internally in the *dose* of about half a grain (0.032 Gm.), and has also been applied to ulcers. It is said to be a powerful oxytocic, but is seldom used.

Mongumo Bark.—For analysis of this Madagascar bark, which is said by E. M. Holmes to resemble the bark of *Ochrosia borbonica* J. F. Gmel. (Fam. *Apocynaceæ*), see *P. J.*, ix, 816. It was examined by Dragendorff, who found *mongumic acid*, resin, waxy substance, a glucoside soluble in water and alcohol, metarabic acid, fatty matter, calcium oxalate and a substance insoluble in alcohol and soluble in water.

Monsonia.—According to John Maberly (*L. L.*, Feb., 1897; July, 1898), certain South African plants belonging to the family of *Geraniaceæ*, having large fleshy roots, are valuable remedies in the treatment of both acute and chronic *dysentery;* such are especially *Monsonia ovata* Cav. and *M. Burkeana* Planch., also certain *Pelargoniums.* Under the name of *t'Namie*, the natives of Namaqualand are said to use the root of *Pelargonium antidysentericum* Kostel. Maberly believes that the *Pelargoniums* are especially valuable in ulceration of the stomach and upper portions of the intestinal tract, and the *Monsonias* when the disease is low down in the intestines. The *dose* of monsonia is given as half an ounce (15.5 Gm.). It is believed that the plants are not poisonous.

Morinda.—From the wood of the *Morinda tinctoria* Roxb. (Fam. *Rubiaceæ*), or *Indian Mulberry,* Anderson (*P. J.* 1886) claimed to have obtained a glucoside *morindin,* which yielded on hydrolysis trihydroxy-methyl-anthraquinone. Oesterle (*A. Pharm.*, 1907, ccxlv), however, was unable to find this glucoside, but did obtain a monomethyl-ether of tri-oxymethyl-anthraquinone, $C_{16}H_{12}O_5$. *M. umbellata* L., *M. citrifolia* L., and the *M. longiflora* G. Don., all yield anthraquinone derivatives. (See Barrowcliff and Tutin, *Trans. British Chem. Soc.*, 1907.) The flowers of *M. citrifolia* contain a red, and the roots a yellow, coloring principle. These plants are used by the African aborigines as remedial agents, but there is no reliable evidence of their therapeutic value.

Morphine Hydrobromide, or *Morphine Bromide* ($C_{17}H_{19}O_3NHBr + 2H_2O$), is made by double decomposition between morphine sulphate and barium bromide (*A. J. P.*, xliv, 447.)

Morphine Meconate. *Morphine Meconas.* ($(C_{17}H_{19}O_3N)_2C_7H_4O_75H_2O$.—This is obtained by the interaction of morphine alkaloid and meconic acid. It occurs in minute, colorless crystals or a yellowish-white powder slightly soluble in water but more so in alcohol. It contains 66.3 per cent. anhydrous morphine and is used after the manner of other morphine salts.

Morphine Methyl Bromide. *Morphosan.* $C_{17}H_{19}O_3NBrCH_3$.—This occurs in needle-like crystals soluble in 20 parts of water. It is asserted that it is free from any of the unpleasant secondary effects of morphine and it has been suggested as a substitute for the latter in the treatment of the morphine habit. The *dose* is one twelfth to one-half of a grain (0.005–0.032 Gm.).

Morphine Stearate. $C_{17}H_{19}O_3N.C_{17}H_{35}.COOH$.—This is made by the combination of morphine hydrochloride with sodium stearate. It forms a white scaly product with a melting point of 85° C. A sweet almond oil solution (1 to 100) of this substance is known as *morphinol* and is used as an anodyne application.

Moxa. *Moxa,* Fr. *Brenncylinder,* G.—These are small combustible masses used to produce an eschar by being burned in contact with the skin. In Japan and China they are made from the leaves or the downy hairs on the leaves and stems of one or more species of *Artemisia. A. chinensis* L. and *A. indica* Willd. (*A. vulgaris* L.) were indicated by the Dublin College; but Lindley states that it is the *A. moxa* of De Candolle which is employed. A similar *moxa* has been made in France, by a similar process, from the leaves of *A. vulgaris.* Moxa were prepared by the Pawnee Indians of North America from the stems of an unidentified species of *Aster.* According to Percy, the dried stem of the ordinary sunflower may be used for moxa. Artificial moxas may be made by impregnating cotton with saltpeter.

Cauterization by fire has been used from time immemorial among savages, half-civilized, and intelligent communities, and is said to have been reintroduced into Europe by the early Portuguese navigators from the Far East. Though at one time much employed for the purposes of revulsion, this form of cauterization has fallen into complete desuetude. The details of its application are described in the 18th edition, *U. S. D.*

Muawin Bark.—This is the bark of a Mozambique tree, which in Eastern Africa is used as an ordeal poison. In appearance and structure it closely resembles the erythrophlœum bark obtained from numerous species of *Erythrophlœum* (Fam. *Leguminosæ*). An alkaloid, *muawine,* was discovered in it by E. Merck, 1891. The hydrobromide, a yellowish powder soluble in water and alcohol. The characteristic test is said to be that with vanadinsulphuric acid, which gives with muawine first a pale green, passing into a pale blue. (H. Jacobsohn, *In. Dis.,* Dorpat, 1892; see also *Merck's Jahresbericht,* 1891.) According to Jacobsohn, the hydrobromide when injected subcutaneously does not cause any irritation, but produces in frogs symptoms similar to those caused by digitalin, and in warm-blooded animals slowing of the pulse, increase of the heart action, elevation of blood pressure, and contraction of the arterioles. The action of muawine is, therefore, like that of digitalin, but is distinguished by being very temporary.

Mucuna. *Mucuna pruriens* De Cand. *Cowhage. Cowage. Setæ Siliquæ Hirsutæ. Pois velus, Pois à gratter,* Fr. *Kratzbohnen, Kuhkrätze,* G.—This is a leguminous climbing plant which grows in the West Indies and tropical countries of both hemispheres. The fruit is a coriaceous pod, shaped like the Italic letter *f*, about four inches long, and covered with brown bristly hairs, which easily separate, and when handled stick in the fingers, producing an intense itching sensation.

The spicula are said to be very destructive to the *round worm,* acting mechanically by penetrating their bodies. Neither the tincture nor the decoction is effective. Cowhage is efficient, but so disagreeable that it has passed out of vogue. The usual mode of preparing it is to dip the pods into syrup or molasses, and scrape off the hairs with the liquid, which is in a proper state for administration when it has attained the consistence of thick honey. The *dose* of this preparation is a tablespoonful (15 cc.) for an adult, a teaspoonful (3.75 cc.) for a child three or four years old, to be given every morning for three days, and then followed by a brisk cathartic.

Muira-Puama.—The dried root of *Liriosma ovata* Miers [*Dulacia ovata* (Miers) Lyons] (Fam. *Oleaceæ*), a Brazilian tree. (For a description of this drug see Youngken, *J. A. Ph. A.,* 1921, x, 690.) According to Th. Peckolt, it contains an alkaloid, *muira-puamine,* and is used by the Brazilian aborigines as an aphrodisiac, also in the treatment of *dysentery.* In *impotence,* ten to twenty minims (0.6–1.3 cc.) of the fluidextract may be taken three or four times a day. (See *M. R.,* 1902.)

Mulberry.—There are in the United States six species of which the three best known are the following: the indigenous *Morus rubra* L., with dark purple fruit; *M. alba* L., introduced from Europe, and at one time extensively cultivated as a source of food for the silk worm, having a white fruit; and *M. nigra* L., a tree of middle size, supposed to have been brought originally from Persia into Italy and widely cultivated. The fruit of the last species has a sweet, mucilaginous, acidulous taste, and abounds in a deep red juice having the sp. gr. 1.060. (*Mori Succus,* Br., 1885.) For analysis of mulberries see *U. S. D.,* 19th ed., p. 1573. In amount of grape sugar the mulberry is surpassed only by the cherry, 10.79, and the grape, from 10.6 to 19.0. Mulberries are refreshing and laxative, and serve to prepare a grateful drink well adapted to febrile cases.

Murexide. *Acid Ammonium Purpurate.* $C_8H_4(NH_4)N_5O_6 + H_2O$.—A fine purple dye-stuff, made by the reaction of nitric acid on uric acid. As resulting from the action of nitric acid on urine, it was supposed by Prout to consist of purpuric acid and ammonia (which belief has been confirmed by further investigation), and hence was named *ammonium purpurate.* It was later made from guano. This was first treated with hydrochloric acid to remove foreign substances, and then with soda to dissolve the uric acid, which is separated by neutralizing the soda with hydrochloric acid. The uric acid is dissolved in nitric acid, the solution is heated, and after it cools ammonia or its carbonate is added, which develops the purple color. Murexide is obtained in crystals, which have a square form, and are a rich green color by reflected, but of a purple-red by transmitted, light. It is slightly soluble in cold water, more so in boiling water and insoluble in alcohol and ether. With potassium hydroxide it forms a rich purple solution. It has been replaced as a dye by aniline colors.

Muscari. *Muscari comosum* (L.) Mill. *Grape Hyacinth* (Fam. *Liliaceæ.*)—In the bulbs of this plant, which grows in Europe and Asia, Curci (*Rép. de Pharm.,* March, 1889) has found *comosic acid,* which he believes to act physiologically like saponin.

Musculus. *Musculus venenosus.*—That certain mussels, or that mussels in a certain condition, are actively poisonous is well ascertained. F. Crumpe (*Dublin Q. J.,* Oct., 1873) has reported collapse with complete paralysis of the voluntary muscles as produced by the mussel. M. Breiger (*D. M. W.,* 1885) has isolated out of mussels the base *mytilotoxine* ($C_6H_{15}O_2N$), which he has demonstrated to possess physiological properties closely resembling those of curare. These poisonous principles are all probably ptomaines, and disappear when the mussel is boiled with sodium carbonate; so that boiling the mussel in an alkaline solution (three and a half grammes per liter of water) renders it harmless.

Musenna Abyssinica.—A substance known as *tœniol* which is claimed to be derived from the rind of the *Musenna abyssinica*, has been recommended as a vermifuge especially for the treatment of *anchylostoma*. According to Liermberger (*B. K. W.*, 1905, p. 390), it is an efficient and nontoxic anthelmintic. The only unpleasant symptom produced was slight giddiness. It is marketed only in the form of capsules of which 10 to 15 may be taken at intervals of ten minutes. After the sixth or seventh capsule there should be allowed an interval of an hour.

Mushrooms and Toadstools. (*Edible and Poisonous Fungi.*)—Notwithstanding the fact that it has been shown that edible fungi, when compared with other articles of food, do not possess a high food value, the interest in the study of the fungi, as well as the consumption of edible forms, is constantly increasing. The study of the fungi is one of the most highly specialized, as there have been up to the present time no less than 64,000 species described. From a food standpoint the differentiation of the edible from the poisonous is one of the most difficult that the novice can undertake, as it is almost impossible to lay down any invariable rules.

The fungi are divided into a number of classes, each of which is again subdivided into sub-classes, orders, and families. The class *Basidiomycetes* includes the largest and most conspicuous of the fungi and all of the mushrooms and toadstools.

The *Basidiomycetes* are divided into two subclasses, the *Hymenomycetes*, or those which have their spore-bearing surface exposed, and the *Gasteromycetes*, or those with their spore-bearing surface inclosed.

It is commonly believed that mushrooms are edible and that toadstools are poisonous; in reality, however, no such distinction should be made. The word "mushroom" is best used in application to any or all of the higher fleshy fungi whether good, bad, or indifferent in respect to edible qualities.

The sporophores (fruiting bodies) of the *Hymenomycetes* are characterized in general in that they arise from a mass of colorless threads, known as "mycelium" or "spawn," produced in the ground, bark of trees, etc. Their first appearance above ground is marked by the production of small solid balls (called buttons), which gradually enlarge, and at length shoot up into a stem or stipe bearing at its summit the umbrella top or "pileus," which is at first closed around the stalk like a closed umbrella and then expands more or less widely, according to the species. The under side of the pileus is the part which bears the spores, which correspond to the seeds of higher plants. In some cases the under surface consists of a series of gills resembling knife blades, which radiate from the top of the stalk to the circumference, like the spokes of a wheel, as in *Agaricaceœ;* in others it consists of a mass of small pores or tubes packed closely together, side by side, as in *Polyporaceœ;* in others of teeth, as in *Hydnaceœ;* in others only slightly wrinkled or undulated, as *Thelephoraceœ*, etc. The *Basidiomycetes* include about 14,000 species which are included in nine orders and subdivided into twenty-five families. A few of the important are the following:

1.—*Agaricaceœ* (the mushrooms and toadstools proper) comprises about 4600 species, some of which are poisonous, as the *Amanitas* (Fly and Deadly Agarics) *Lactarius* (with a milky juice), whereas others are edible, as *Agaricus campestris* L., the common mushroom, *Cantharellus cibarius*, Fr., the *chanterelle*, etc.

2.—*Polyporaceœ* (pore-fungi) includes about 2000 species, many of which are parasites on trees and destructive to timber; some are edible, as *Boletus edulis* Bull., whereas others are poisonous, as *B. satana* Lenz.

3.—*Hydnaceœ* (teeth-bearing fungi): Most of the species are too small and woody to be eaten. *Hydnum repandum* forms "fairy rings" in woods.

4.—*Thelephoraceœ:* Most of the species are small, and the larger species are tough and leathery.

5.—*Clavariaceœ* (coral-shaped fungi) includes some large fungi; none are poisonous and some, as *Clavaria flava* Schaeff, are palatable.

Of these, the most important group are the *Agaricaceœ* both from the point of view of the toxicologist and the epicure.

It is not possible in this limited space to even mention the various poisonous and edible fungi that experience has demonstrated as such. The number of species which have been eaten or experimented with, however, is small compared to the number recognized by botanists. Many students of fungi have formulated rules for distinguishing edible from poisonous fungi. "The different popular tests for distinguishing edible from poisonous fungi, such as, for instance, the blackening of a silver coin or spoon when placed in a mass of poisonous fungi while they are being cooked, are all absolutely worthless." The only safe rule is to use no mushroom which the collector is not absolutely sure from previous experience is edible.

The *common mushroom* (*Agaricus campestris* L.) is practically the only species cultivated in this country, and is the only fresh species sold in the northern markets during the winter months. It is found wild in open grassy fields and pastures in great abundance in August and September. It is not common on the mountains, never found in woods, and never grows on trees or fallen trunks. The color of the stalk and pileus varies from a whitish shade to drab, but the color of the gills, a point which should never be overlooked, is at first pinkish and then a brownish-purple. The stalk is cylindrical and solid, and has, rather more than half way up, a membranous collar called the ring; but there is no membrane or scales found at the base of the stalk, which appears to come directly out of the ground. "In specimens which are not fully expanded there is a thin membrane or veil which extends from the stalk to the margin of the pileus. When the veil is ruptured, exposing the gills behind, a part remains attached to the stalk forming the ring already referred to. In older specimens the ring shrinks, but generally a mark remains showing where it has been attached."

Two of the most poisonous forms resembling the common mushroom, and which have been eaten in mistake for it, are the deadly agaric and fly agaric.

The *fly agaric* (*Amanita muscaria* (L.) Pers.), so called because decoctions have been used for killing flies, is in some localities much more abundant than the common mushroom. It is seldom found in the grassy pastures preferred by the common mushroom, but more generally in poor soil, especially in groves of coniferous trees. "It grows singly and not in groups and differs from the common mushroom in having gills which are always white, never pink or purple and in having a hollow stem, which is bulbous at the base and clothed with irregular fringy scales on all the lower part.

The pileus varies in color from a brilliant yellow to orange and a deep red, the yellow and orange being more frequent than the red. The surface is polished, and has scattered over it a larger or smaller number of prominent, angular warty scales which can be easily scraped off. The gills and stalks are white, and there is a large membranous collar which hangs down from the upper part of the stem."

The *deadly agaric* (*Amanita phalloides* (Pers.), Fr.), so named because it probably has been more frequently the cause of death than any other fungus, prefers a damper and less sandy soil than the fly agaric and is not pre-eminently an inhabitant of grassy pastures. It is common in woods and like the fly agaric grows singly. "The pileus is often a shining white, but may be of any shade from a dull yellow to olive, and when wet is more slimy than the common mushroom or the fly agaric. It has no distinct scales and only occasionally a few membranous patches on the pileus. The gills and stalks are white, and the latter has a large ring like the fly agaric and is hollow, or when young, is loosely filled with cottony threads, which soon disappear. The base of the stalk differs from that of the fly agaric in having more bulbous volva, the upper part bordered by a sac-like membrane."

The list of edible and poisonous fungi are relatively long, and while most belong to the *Hymenomycetes*, some are also yielded by the *Gasteromycetes*, as the puff-balls and carrion fungi. The *giant puff-ball, Lycoperdon bovista* (*L. giganteum* Batsch), found in the region of San Francisco Bay, is not rarely forty inches in diameter.

We may conveniently consider the poisonous mushrooms in four groups following the divisions of Kobert. (*Ueber Pilzvergiftung*, 1891.)

In the first group is the genus *Lactarius* which owe their toxic properties to the presence of an irritant resin. Some of this genus, as *L. deliciosus*, are stated to be edible, but most of them produce severe or even fatal gastric enteritis.

The second group contains species belonging to the genus *Helvella*, whose juice contains *helvellaic acid*, isolated by Boehm. It is asserted that these fungi, when thoroughly dried, are not poisonous, and that hot water also extracts from them the poisonous acid, so that boiling makes them edible. The chief physiological action of the acid seems to be to destroy the red blood corpuscles, and, probably by such action, to produce vomiting, hemoglobinuria, jaundice, irritation of the kidneys, etc.

The third and most important group are the *Amanitas*. They are the most common source of mushroom poisoning, not only because of their resemblance to many of the edible species, but also because of the virulence of their effects. The most important of this species is the *A. phalloides*, or *skunk mushroom*. According to Ford (*J. P. Ex. T.*, 1910, 1, p. 275), they contain two poisonous substances, one being hemolytic, and the other causing degenerative changes in the various internal organs, especially the liver, kidneys, spleen and muscles. The *amanita-hemolysin*, which is probably identical with the *phallin* of Kobert, appears to be glucosidal, and because it is destroyed by heat, probably plays little part in human poisoning. The nature of *amanita-toxin* is not yet determined, but poisons of a similar nature appear to be widespread throughout the whole of the genus.

In the fourth group are included those which contain *muscarine*. This alkaloid was first obtained from the *Amanita muscaria*, but is also found in the *A. pantherina*, the *Russula emetica*, in *Boletus luridus*, *B. Satanus*, and, according to Ford (*J. P. Ex. T.*, 1911, ii, p. 549), occasionally also in the *Clytoscybe dealbate*, which has by some been classed as an edible fungus. Decoctions of the *Amanita muscaria* are used to poison flies, whence the common name of the *fly agaric*. The inhabitants of the Caucasus also use this fungus as an intoxicant. The *A. pantherina* is used in Japan for like purposes.

Muscarine was first obtained in a state of purity by Schmiedeberg and Koppe. (*Das Muscarin*, Leipzig, 1869.) The alkaloid may be produced artificially by gently heating choline platino-chloride with strong nitric acid. Potassium chloride is used to decompose the muscarine platino-chloride and produce muscarine hydrochloride; treatment with moist silver oxide yields the muscarine as a hydrate ($C_5H_{15}O_3NH_2O$). Muscarine is closely related in its chemical composition and structure to betaine and choline. Muscarine resembles pilocarpine in its physiological action, and is antagonistic to atropine. It increases the secretions of the sweat, salivary and lachrymal glands, contracts the pupil, slows the pulse, and causes motor weakness. The reduction in the pulse rate is due to stimulation of the pneumogastric nerve, and after very large doses diastolic arrest of the heart occurs. If atropine be given so as to paralyze inhibition the cardiac movements reoccur. The vasomotor nerves are said to be paralyzed. There is a stimulation of the muscles of the intestines, bladder and spleen. The abdominal secretions are greatly increased.

The symptoms of mushroom poisoning will vary greatly according to the special fungus which has been ingested. In the case of the deadly agaric (*Amanita phalloides*) which is the most common source of toadstool poisoning, the symptoms usually do not appear for several hours after the fungus has been eaten. They consist of great prostration and collapse, cold sweats, stupor, sometimes preceded by delirium, convulsions, frequently cyanosis and not rarely icterus. There is usually, also distinct fever, and either hemoglobinuria or methemoglobinuria, and evidence of irritation of the kidney is shown by the presence of albumen, or partial suppression of the urine. When the poisoning is produced by fly agaric, to these symptoms will be added those of muscarine poisoning, namely, profuse salivation, contracted pupils and slowing of the pulse. In the poisoning by the lactarii the symptoms are those simply of violent inflammation of the alimentary tract, vomiting, purging and collapse. In poisoning by the *Helvellæ* the symptoms resemble those produced by the *Amanitas*.

After the poison has once entered the system but little can be done to save the patient. Our utmost efforts should be directed to preventing absorption. A promptly acting emetic, such as apomorphine, should be administered to produce vomiting. Secheyon (*P. J.*, 1910, liiiv, p. 492) highly recommends animal charcoal for the purpose of adsorbing the poison, and thus preventing its entrance into the system. At least a tablespoonful, stirred up in water, should be administered, and repeated libitum. It is also advisable to administer atropine hypodermically in one-sixtieth-grain doses (1 mgm.), as it is the physiological antagonistic to muscarine, and may prove a life-saving remedy in poisoning by fly agaric, and by its general stimulant effect will also exercise a feeble influence in combating the collapse even although due to other forms of poisoning. A rapidly acting cathartic should also be administered to cleanse the intestinal tract. Aside from these measures, the treatment is purely symptomatic—the use of opium if necessary to check the diarrhea and vomiting, and various stimulants to maintain the circulation and respiration.

Musk. *Moschus* U. S. IX, *Deer Musk. Musc,* Fr., *Bisam,* G., *Muschio,* It., *Almizcle,* Sp.—"The dried secretion from the preputial follicles of *Moschus moschiferus* Linné (Fam. *Moschidæ*). Preserve it carefully in glass-stoppered bottles." *U. S. IX.*

Musk is no longer recognized by either the U. S. or British Pharmacopœia.

The *musk-deer* is a small animal about 20 inches in height, differing from other deers in that there are no antlers in either sex. It is an extremely wary animal of a deep iron gray color, inhabiting the mountainous districts of Central Asia where it is hunted for its hide as well as for the peculiar secretion known as musk. This latter is contained in an oval, hairy, projecting sac, found only in the male, situated between the umbilicus and the prepuce, from two or three inches long, and from one to two broad, opening by a small hairy orifice at its anterior part, and marked posteriorly by a groove or furrow which corresponds with the opening of the prepuce. It is lined internally by a smooth membrane, thrown into a number of irregular folds, forming incomplete partitions. In the vigorous adult animal, the sac sometimes contains six drachms of musk; but in the old, seldom more than two drachms, and none in the young. As soon as the animal is killed, the sac is cut off, dried, and sent into the market.

The so-called *Tonquin musk* (which really comes from the province of Sze-Chuen in China) and the *Tibetan musk,* which are the preferred varieties, appear in commerce as flattish, circular or oval cakes called "pods," of about 5 to 7 centimeters in diameter and 2 or 3 cm. in thickness. They are convex and hairy on one side, flat and destitute of hair on the other. The hairs are brownish-yellow, grayish, or whitish, stiff and short, and arranged concentrically around the orifice of the sac. The pods of the *Yunan musk,* which is obtained in the Chinese province of that name, may easily be distinguished by their more nearly spherical outline. The *Assam* and *Nepaul musk* are in spherical pods which are much smaller than those of the Tonquin variety. A variety known as *Cabardine musk* is exported from China into Japan, but does not appear to enter this country.

Fresh musk is an unctuous, brownish, semi-liquid—but in the dried condition, as it appears in our markets, is in grains or lumps concreted together, soft and unctuous to the touch, and of a reddish-brown or ferruginous color resembling that of dried blood. Some hairs of the pod are generally mixed with it. It was officially described as "usually in small irregular granules, not more than 2 mm. in thickness, blackish with a few brown fragments and becoming somewhat grayish on aging; glistening and somewhat oily; odor peculiar, penetrating, powerful and peristent; taste somewhat bitter. Add a few granules of Musk to 2 mils of water in a watch crystal and stir with a glass rod; a light brown solution is obtained. The undissolved portion consists of irregular fragments containing a finely granular substance, numerous rod-like bacteria and occasionally the hyphæ of a fungus. Add a drop of iodine T.S. to a few granules of Musk on a slide and examine it under the microscope; the particles are not colored blue or bluish-black (*starch*). Add a few granules of Musk to 2 mils of alcohol contained in a watch crystal; the grains sink to the bottom, and upon stirring with a glass rod, a pale brown, slightly cloudy solution is obtained, leaving a somewhat oily stain upon the upper portion of the watch crystal as the alcohol evaporates; the undissolved portion or residue resembles that obtained with the aqueous mixture, except that the particles are less disintegrated. Add a few granules of Musk to 2 mils of chloroform in a watch crystal; the grains float on the surface and upon stirring with a glass rod, the solution remains nearly colorless, and as it evaporates there separates around the particles a small quantity of a whitish, oily or fatty substance. Not less than 50 per cent. of Musk is soluble in water, the solution having a strong, distinctly characteristic odor, and a slightly acid reaction. Not less than 10 per cent. of Musk is soluble in alcohol, the solution being of a light, yellowish-brown color and becoming slightly turbid upon the addition of water. Musk loses not more than 15 per cent. of moisture when dried to constant weight in a desiccator over sulphuric acid. Musk yields not more than 8 per cent. of ash." *U. S. IX.*

The odor is strong, penetrating and so diffusive that one part of musk communicates its odor to more than 3000 parts of inodorous powder. (Fée.) In some delicate individuals it produces headache and other disagreeable symptoms, and it has even caused convulsions. The color of the powder is reddish-brown. Musk is inflammable, burning with a white flame, and leaving a light spongy charcoal. It yields, upon analysis, a great number of proximate principles. Among these are fatty substances—such as stearin, olein and cholesterin—various proteins, various inorganic salts, and a small amount of a thick, colorless oily substance, apparently related to the ketones; this, which has been called *muskone,* possesses a powerful musk-like odor. Geiger and Reinman found a peculiar bitter resin, a peculiar substance in part combined with ammonia, and lactic acid both free and in combination. The action of potassium hydroxide upon musk is accompanied with the extrication of ammonia and an increase of its peculiar odor. By the influence of heat and moisture long continued, ammonia is developed, which acts upon the fatty matter, producing a substance resembling adipocere. When kept in glass bottles, in a situation neither moist nor very dry, it remains for a great length of time without material change. The odor of musk is very much diminished by mixing it with emulsion or syrup of bitter almond, or with cherry-laurel water. From the experiments of Wimmer, it appears that musk loses its odor when rubbed with golden sulphide of antimony, and reacquires it on the addition of a little solution of ammonia. Camphor rubbed up with musk is also said to destroy its odor.

The price of this medicine is so high, and its sources are so limited, as to offer strong temptations to adulteration, and little genuine unmixed musk is to be found in the market. A common practice in the East is to open the sac and to introduce all sorts of substances as dried blood, sand, resins, lead shot, etc. Some of these adulterations are obvious on even a casual observation but others are difficult of detection. The only safe rule is to purchase the musk in the sac, which should present no evidence of having been opened. The slit is sometimes carefully sewed up, sometimes glued together. The former condition may be discovered by close inspection, the latter by immersion in hot water. When the bag is made from any other portion of the skin, the difference may be detected, according to Neligan, by the microscope. The genuine hairs exhibit innumerable cells, which are wanting in the spurious. (*Chem. Gaz.*, Feb., 1846, p. 79.) Musk which burns with difficulty, has a feeble odor and a color either pale or entirely black, feels gritty to the finger, is very moist so as to lose much weight in drying, or contains obvious impurities, should be rejected. For an account of the effects of numerous reagents on musk, and other modes of identification, as well as of detecting adulterations, see Bernatzik (*A. J. P.*, 1861).

There are a number of other animals that secrete substances with strong odors, more or less resembling that of true musk. Among these is the beaver (see under *Castor*) and civet cat (see *Civet*). Under the name of *American musk* a product of the *musquash* or *muskrat* (*Fiber Zibethicus*) has been used as a substitute for true musk in perfumery, although the odor is not identical.

By the preceding generation of physicians, musk was one of the most highly esteemed remedies; of recent years, however—whether because of difficulty in obtaining it or the lack of real virtue is uncertain—it has very largely passed out of vogue. It was attributed with remarkable restorative powers in the nervous exhaustion of *low fevers*, such as *typhoid* or *adynamic pneumonia*. It was also highly esteemed for its antispasmodic action, especially in *hiccough* and in *laryngysmus stridulus*. According to some authorities, musk rapidly loses its power of influencing the nerve centers, and for this reason, and on account of its costliness, its employment should always be delayed until severe nervous exhaustion becomes alarming. It may be given in pill or emulsion. The U. S. IX recognized a 5 per cent. tincture made with a menstruum of diluted alcohol.

Dose, from five to fifteen grains (0.32–1.0 Gm.).

Musk, Artificial. *Moschus Factitius.*—An artificial musk introduced as a patented preparation, called "*Musk Baur*," from the name of the discoverer, A. Baur, is *trinitrometabutyltoluene*, $C(CH_3)_3.C_6H(NO_2)_3CH_3$. It is prepared by adding tertiary metabutyltoluene slowly in the cold to five times its weight of a mixture of concentrated nitric and sulphuric acids, and afterwards heating the mixture for from eight to nine hours on a water bath. There are several closely related compounds, all derived from butyltoluene, which are commercially known as "artificial musk." They melt at temperatures ranging from 89° C. to 96° C. They are insoluble in water but soluble in alcohol, ether, benzene, chloroform, and petroleum benzin.

Artificial musk has been esteemed to be antispasmodic and has been highly commended in *whooping cough* and *spasm of the glottis* of children. *Dose*, ten grains (0.65 Gm.); for a child two years old, from half a grain to a grain (0.032–0.065 Gm.), every two or three hours.

Mutisia. *Mutisia viciæfolia* Cav.—This composite, a native of Chile, is stated to be a valuable anti-spasmodic, useful in *hysteria* and *croup;* it is also a cardiac tonic.

Myrtus. *Myrtus communis* L. *Myrtle.* (Fam. *Myrtaceæ.*)—This is a handsome shrub with strongly scented leaves and flowers, indigenous to Mediterranean countries. From the leaves of this plant is distilled a volatile oil which, under the name of *myrtol*, is employed in medicine. This oil contains pinene, cineol and a characteristic alcohol, *myrtenol*. The mixture usually known as *myrtol* is collected between 160° and 180° C. Myrtol has been recommended as an antiseptic and a powerful stimulant to the pulmonic and genito-urinary mucous membranes, and useful in chronic *bronchitis*, *cystitis*, or *pyelitis*. Barker and Rowntree (*J. H. H. B.*, 1918, xxix, 215) have described cases of poisoning from myrtol with symptoms similar to those caused by oil of eucalyptus. *Dose*, from one to two minims (0.06–0.13 cc.), given in capsules, from four to eight times a day. A. de Vevey (*R. T.*, lxiii, 1896) has used the 10 per cent. solution in sterilized olive oil hypodermically in doses of eighty to one hundred and sixty minims (5–10 cc.) once or twice in twenty-four hours.

Nabalus. *Prenanthes alba* L. *Rattlesnake Root. White Lettuce. Cancer Weed. Gall of the Earth. Lion's Foot.* (Fam. *Compositæ.*)—In certain portions of Virginia and North Carolina, where this perennial herb grows, great value was attached to it in *rattlesnake bite*. The milky juice is taken freely internally, and its leaves steeped in water which is locally applied and frequently changed. The plant is also used in *dysentery*, and N. B. Williams has found tannin in the rhizome. (*A. J. P.*, 1887.)

Nance Bark.—This bark is believed to be obtained from the *Malpighia glabra* L. (*Barbados Cherry*) (Fam. *Malpighiaceæ.*), a glabrous shrub with opposite, ovate to elliptic leaves and umbels of red flowers, found growing from South Texas to northern South America and in the West Indies. It is much used in Mexico for tanning, and, according to F. Holberg, contains 26.2 per cent. of tannin. (*A. J. P.*, xvi, 239.)

Naphthalan. *Naftalan.*—This is a greenish-black soft mass, prepared by the fractional distillation of naphtha obtained from the Armenian highlands, having a slightly empyreumatic odor, a neutral reaction, and a specific gravity of 0.89. It melts at 70° C., is insoluble in water and glycerin, but mixes readily with fats and oils, and is soluble in ether and petroleum benzin. It has been recommended by Rosenbaum and others as very efficacious in the treatment of *pruritus* and *burns*, as well as in *chronic eczema*, *sycosis*, and other parasitic skin affections, and as having a range of usefulness closely parallel to that of the oil of cade. Applied as a paste, 50 per cent. naftalan, 25 per cent. each of zinc oxide and of starch, with or without 2 to 5 per cent. of menthol. (See *Praktitchesky Vratch*, vol. i, No. 31.)

Kupzis recommends a naftalan which is a combination of the higher boiling portions of Caucasus naphtha from the naphtha residues, having a sp. gr. 0.94–0.97, and deprived of odor by vacuum distillation, by dissolving from 6 to 8 per cent. of perfectly neutral stearine soap in it. (*Ph. Ztg.*, 1905, 499.)

Naphthalene. *Naphthalenum. U. S. VIII. Naphtalin. Naphthalin. Tar Camphor.* $C_{10}H_8 = 128.06$.—"A hydrocarbon obtained from coal-tar, and purified by crystallization. It should be kept in well-stoppered, amber-colored bottles." *U. S. VIII.*

This may be obtained by subjecting coal-tar to distillation, when it passes over in the middle oil and heavy oil; in the fractions of the latter it often constitutes the main constituent, causing it to become almost solid on cooling. It is frequently produced during the dry distillation of organic bodies. It is made very extensively and cheaply at present, the sublimed commercial product being nearly pure. It is a white, shining, crystalline substance, fusible at 80° C. and boiling at 218° C., but volatilizing with vapor of water. According to Kopp, its sp. gr. in the liquid state is 0.9774; according to Alluard, at 98.8° C., 0.9628.

It was officially described as in "colorless, shining, transparent laminæ, having a strong, characteristic odor resembling that of coal-tar, and a burning, aromatic taste; slowly volatilized on exposure to air; by exposure to light acquiring a brownish color. Insoluble in water, but when boiled with it, the water acquires a faint odor and taste; soluble in 13 parts of alcohol at 25° C. and very soluble in boiling alcohol; also very soluble in ether, chloroform, carbon disulphide, and fixed or volatile oils. Naphthalene volatilizes slowly at ordinary temperatures, but rapidly when heated. It also volatilizes with the vapors of water or alcohol. At 80° C. it melts, and at 218° C. it boils. Its vapor is inflammable, burning with a luminous but smoky flame. When ignited, it is consumed, leaving no residue. Naphthalene is neutral to litmus paper moistened with alcohol. On shaking a small portion of naphthalene with concentrated sulphuric acid, the acid should remain colorless, and should not acquire more than a pale reddish tint if the mixture be heated for five minutes on a water-bath (absence of *impurities derived from coal-tar*)." *U. S. VIII.*

Naphthalene is possessed of antiseptic properties, and is poisonous to most fungi and probably to most insects. Under the name of "*tar camphor*," it has largely supplanted true camphor as a means of preventing the deposition by moths of eggs in woollen clothing, and of preventing the destruction by insects in natural history museums. Castellani and Jackson (*Jour. of Tropical Medicine and Hygiene*, 1915, xviii, p. 253) rank naphthalene as the most practical insecticide powder for the protection of the body against vermin and hence against the diseases, such as *typhus fever*, carried by them; fleas exposed to its vapors were killed within 30 to 60 minutes and although it required a longer time to kill lice it seems to exercise a strong deterrent effect. Blaschko (*B. M. W.*, 1915, xli) highly recommends the use of a 5 per cent. naphthalene petrolatum as protective against typhus fever. It has been used for its antiseptic action in various *skin diseases* and to a less extent as a surgical dressing. In internal medicine it has been employed with asserted excellent results both as vermifuge and as an intestinal antiseptic in *enteritis*. For these latter purposes, however, it has been almost entirely superseded by its derivative, naphthol. *Dose*, one to five grains (0.06–0.3 Gm.) Eighty grains are said to have been given in a day without deleterious effects, but J. A. Otte (*Chinese Med. Missionary Journ.*, xi, 1897) violently poisoned himself by eight grains of naphthalene. The symptoms were excessive vomiting and purging and great abdominal pain, followed by nephritis. Moreover, employees in gutta-percha works, where it is largely used, are said to be occasionally thrown into a peculiar condition of delirious intoxication.

Narcissus. *Narcissus Pseudo-narcissus* L. *Daffodil. Trumpet Daffodil. Narcisse des prés, Porillon*, Fr. *Gelbe Narcisse*, G. (Fam. *Amaryllidaceæ.*)—Both the bulb and the flowers of this common and widely cultivated popular European garden plant have been used in medicine. The bulb is tunicated and averages one and one-half to two inches in diameter. The flowers are about two inches long, pale yellow, the corona crenate to somewhat crenate-fimbriate, the six stamens inserted near the base of the perianth and much shorter than the corona. The flowers have a feeble peculiar odor, and both have a bitter mucilaginous taste. They are an uncertain emetic. It is probable that the flowers of the wild European plant are more powerful than those of the cultivated. Gerrard found in 1877 in these bulbs a crystalline neutral principle and an alkaloid *narcissine* (*pseudonarcissine*). This base, which occurs in a number of the *Amaryllidaceæ*, has been shown by Asahina and Sugii (*A. Pharm.*, 1913, ccli, 357) to be identical with *lycorine*, $C_{16}H_{17}O_4N$, found by Morishima (*A. E. P. P.*, 1897, xl). It crystallizes in colorless prisms with a melting point of 270° C. According to Ruiger, the alkaloid obtained by Gerrard from the bulb of the flowering plant dries the mouth, checks perspiration, dilates the pupil, especially when applied locally, quickens the pulse, and acts on the heart of the frog antagonistically to muscarine and pilocarpine, while the alkaloid taken from the bulb after flowering causes salivation and perspiration, internally taken contracts the pupil, and topically applied dilates it slightly. (*J. P.*, i, 436.) In France, narcissus flowers have been used as an antispasmodic. The *dose* of the powder, to produce an emetic effect, varies, according to the statements of different physicians, from twenty grains to two drachms (1.3–7.7 Gm.); while the extract is said to cause vomiting in the *dose* of two or three grains (0.13–0.20 Gm.). The bulb is most powerful in the recent state.

Narcophine. $C_{22}H_{23}O_7N.C_{17}H_{19}O_3N.C_7H_4O_7 + 4H_2O$.—This is a double salt containing one molecule of morphine and one of narcotine united to meconic acid. Although it corresponds to only 38 per cent of morphine hydrochloride, according to Straub (*Biochem. Zeit.*, 1912, xlii, p. 316), it equals the latter salt in narcotic power. On the other hand Zehbe (*M. M. W.*, 1912) finds that it is somewhat weaker in equal dose than morphine, but the dose may be safely increased without the production of the common secondary effects of morphine. It is given in *doses* of from one-sixth to one-half grain (0.010–0.032 Gm.).

Narcyl. *Ethyl-narceine-hydrochloride.* $C_{25}H_{31}O_8N.HCl$.—It is sparingly soluble in cold water, readily soluble in alcohol; its solubility in water is greatly increased by the presence of organic acids. The various alkaloidal reagents precipitate it and the addition of chlorine water followed by ammonia will show a cherry-red color with a fresh solution of this compound. The precipitate formed by the addition of sodium hydroxide redissolves in an excess of the precipitant (distinction from narceine). According to Pouchet and Chevalier (*B. G. T.*, 1904, p. 779), its physiological action is very similar to that of codeine. It has been used as a cough sedative in *phthisis*, *bronchitis*, and *whooping cough*. *Dose*, half to one and a half grains (0.032–0.096 Gm.).

Nard.—Several aromatic rhizomes were known to the ancients under the name of *nardus*, distinguished, according to their origin or place of growth, by the names of *Nardus indica*, *Nardus celtica*, *Nardus montana*, etc. They are supposed to have been derived from different valerianaceous plants. Thus, the *Nardus indica* is referred to *Nardostachys Jatamansi* (Roxb.) DC. (*Valeriana Jatamansi* Roxb.), of Bengal, the *Nardus Celtica* to *V. celtica* L., inhabiting the Alps, Apennines, etc., and the *Nardus montana* to *V. tuberosa*, which grows in the mountains of the south of Europe. The *Indian nard*, sometimes called *Syrian nard*, is still occasionally to be found in commerce under the name of "*Nardus Root*." It is a dark gray, short rhizome from one to three inches long, beset with a tuft of soft, light brown, slender fibers, of an agreeable odor, and a bitter aromatic taste. It was formerly very highly esteemed as a medicine, but is now almost out of use. Its properties are analogous to those of valerian.

Naregamia. *Goanese Ipecacuanha.*—The root of *Naregamia alata* Wight and Arn. (Fam. *Meliaceæ*), of Western India, has been employed as an emetic, as an hepatic stimulant in *dysentery*, and in small doses as an expectorant in *bronchitis*. Drasche, of Vienna, confirms the value of the drug. (*Cb. G. T.*, 1890.) In it Hooker has found an alkaloid, *naregamine*, an oxidizable fixed oil, and a wax. (See *P. J.*, vol. xv, 1887.) The *dose* of a concentrated tincture (1 to 4) is from five to ten minims (0.3–0.6 cc.); as an emetic, from fifteen to thirty minims (0.9–1.8 cc.).

Nastin.—This substance which was originally prepared by Deycke and Reschad (*D. M. W.*, 1907, p. 89) from a culture of the bacilli of leprosy is stated by the discoverers to be a peculiar paraffin-like substance of fruity odor and composed of a glycerin ester and *nastinic acid* (a fatty acid of high molecular weight). It was at one time thought to be characteristic of these bacteria, but has been found in the bodies of other bacteria. It is claimed that the injection of this substance causes the death of the leprosy germs and hence arrests the disease. It is not claimed for it that it will cure the lesions which are already present, but simply that it prevents further progress of the disease. It is employed in the form of a 1 per cent. solution in warm sterile olive oil of which at first eight minims (0.5 cc.) and later 1 cc. is injected weekly. Kupffer (*Cb. G. T.*, 1909, p. 311) has also obtained favorable results from its employment.

Neopyrin. *Valinopyrin. Valeryl-amino-antipyrine.*—This is in the form of odorless crystals, of very bitter taste, and a melting point of 203° C. It is sparingly soluble in water, more so in alcohol, and freely so in chloroform.

Bachem (*Th. M.*, 1909, p. 588) has experimented upon the lower animals with valeryl-amido-antipyrine and also with its bromine derivative. The latter, however, he finds is too toxic to give promise of therapeutic usefulness, although it exercises a marked antipyretic action. He finds *neopyrine* is less poisonous than antipyrine and believes that it may prove a useful antipyretic. *Dose*, five to ten grains (0.32–0.65 Gm.).

Nerium. *Nerium Oleander* L. *Oleander*, *Rose Bay*. *Laurier Rose*, *Laurose*, Fr. *Oleander*, *Rosenlorbeer*, G. (Fam. *Apocynaceæ.*)—This widely cultivated ornamental evergreen shrub is a native of the Mediterranean region and Asia. It flowers in summer, the blooms being salver-shaped, variously colored and arranged in terminal cymes. Its leaves are lanceolate and are arranged in whorls of 2 or 3. It is affirmed to have been used from time immemorial in portions of Southern Europe for destroying rats, and a number of cases of poisoning by it have been reported. (For collection, see *T. G.*, July, 1888.) The symptoms have been vomiting, abdominal pain with frequent cries, dilatation of the pupil, vertigo, convulsive movements, insensibility, small, very slow pulse, and in fatal cases epileptiform convulsions with coma ending in death. The action on the heart has in some cases in which death has not ensued, been very pronounced, the pulse for five days remaining as low as forty per minute. The infusion made from four ounces of the root is affirmed to have taken life.

The active principle of oleander seems to be the glucoside *oleandrin*, discovered by Leukowsky, but more closely studied by Schmiedeberg (*A. E. P. P.*, 1883, xvi, 145), who proved its glucosidal character and found it to be a powerful cardiac poison of the digitalis type. A number of other supposedly active principles have been described but their existence cannot be considered as definitely established. Among these may be mentioned the *neriodorin* of Greenish (*A. J. P.*, 1881, 350), the *neriin* of Schmiedeberg and the *karabin* of Bose (*P. J.*, 1901, 553). Dubigadoux and Durieu affirm that they have obtained strophanthin from the oleander of Algeria. Leulier found in oleander bark a glucoside which seems to be identical with the lævo-strophanthin of Thoms. (*P. J.*, lxxxvii, p. 407.) Pieszczek obtained from oleander bark a principle which he named *rosaginin*, which was very poisonous, resembling strychnine in its action. (*A. Pharm.*, ccxxviii, 352.) (See also *M. R.*, 1911, and *J. P. C.*, 1912, 108.)

Pouloux (*B. G. T.*, May 15, 1888) and Freiherr (*Aerzt. Rund.*, 1899) have used oleander clinically in the treatment of *heart disease* as a substitute for digitalis with asserted success. Its diuretic action is said to be very marked, and not rarely it acts as a cathartic. Freiherr asserts that it is safer than digitalis in atheromatous diseases. Freiherr used it in infusion or tincture, representing as the daily dose from three-quarters to one and a half grains (0.048–0.096 Gm.) of the dried oleander bark, one and a half to three grains (0.096–0.2 Gm.) of the fresh bark, one and a quarter to three and a half grains (0.08–0.23 Gm.) of the dried fruit. Pouloux's dose of the extract was three-quarters of a grain (0.048 Gm.). Orfele has used the dried flowers—dose, three grains (0.2 Gm.) in substance, or from ten to twenty minims (0.5–1.0 cc.) of a 10 per cent. tincture—with success.

Nervocidine.—This is a yellow, amorphous, hygroscopic powder, readily soluble in water, which is affirmed to be an alkaloid, obtained from the East Indian plant, *Gasu Basu*, and to be a powerful local anesthetic, its 1 per cent. solution producing marked anesthesia of the cornea. It is stated to be so irritant that its 2 per cent.

solution will cause in dogs and rabbits an ulcerative keratitis along with an anesthesia which lasts for days. It is affirmed, further, to be a paralyzing poison, causing such symptoms as to almost invalidate its usefulness and render it unsafe. (*L. L.*, 1902, 1.)

Neuraltein. *Neraltein. Sodium p-ethoxyphenyl-amino-methane-sulphonate.* $C_2H_5O.C_6H_4NH.CH_2SO_3Na + H_2O$.—This is in the form of white crystals which are soluble in 10 parts of water, and very soluble in boiling water.

It is claimed that it has the advantage over other derivatives of paramido-phenol of being much less toxic. Astalfoni (*W. K. W.*, 1909, p. 119) has found that it causes an increase in the blood pressure with slowing of the pulse. The primary phase of hypertension lasts about an hour and is not followed by depression. Gottlieb (*Cb. I. M.*, 1909, xxx, p. 1049) has employed it in a number of febrile conditions. He finds that it exercises in many cases a distinct antipyretic effect but that its analgesic action is much inferior to that of other coal-tar antipyretics. Skutetzki (*M. M. W.*, 1909, p. 2314) on the other hand has obtained a marked relief of pain in *rheumatic fever* and believes that it is of value rather as an analgesic than an antipyretic. It may be given in *doses* of eight grains (0.5 Gm.) three to six times a day.

Neurodin. *Acetoxane. Acetyl-p-oxy-phenyl-urethane.* $C_6H_4(OCOCH_3)NH.COOC_2H_5$.—Forms colorless, odorless crystals, fusing at 87° C., soluble in 1400 parts of cold water. It is used as an anodyne in *neuralgia* in *doses* of from fifteeen to twenty grains (1–1.3 Gm.).

Neurolæna. *Neurolæna lobata* R. Br.—From the leaves of this composite plant, used in the Windward Islands as a substitute for quinine, and in *dysentery*, B. H. Paul and A. J. Cownley obtained an uncrystallizable alkaloid. (*P. J.*, ix.)

Neuronal. *Acetobromal. Diethylbromacetamid.* $Br(C_2H_5)_2CO.NH_2$.—A crystalline substance slightly soluble in cold water, but decomposed in hot water. It possesses a camphoraceous odor and a bitter cooling taste. Melting point 66° to 67° C. It has been used as a somnifacient by a number of clinicians with more or less satisfactory results. While apparently a useful drug in the treatment of the milder forms of *insomnias*, it does not seem to possess sufficient power in the severer cases. Heineicke (*Med. Clin.*, 1906, 572) observed that when used repeatedly, the remedy is liable to lose its power. The *dose* is from fifteen to thirty grains (1–2 Gm.).

Neutral Red. *Dimethyldiamidotoluphenazine Hydrochloride.—Toluylene red* has been employed by Schlaepfer (*M. M. W.*, 1908, No. 36) as a means of testing the motor function of the stomach. Nine cc. of a one-half per cent. solution of the dye is mixed with a meal and the passage of the gastric contents through the pylorus is indicated by the coloration of the urine. The remainder of the contents of the stomach are then siphoned out and the activity of the digestion may also be approximately ascertained by a degree of change in the color of from red to yellow which is caused by the gastric secretions.

New Sidonal. *Neusidonal.*—This preparation is asserted by its promotors to be the inner anhydride of quinic acid, but analysis has proved it to be irregular proportions of quinine, $C_7H_{10}O_4$, and quinic acid, $C_7H_{12}O_5.H_2O$, usually containing 75 per cent. of the former and 25 per cent. of the latter. It is administered in the treatment of *gout*, one hundred and fifty grains (9.8 Gm.) being given daily in divided *doses*.

Nickel. *Niccolum.*—T. P. A. Stewart (*A. E. P. P.*, Bd. xviii, 154) finds that in frogs soluble preparations of nickel produce palsy with convulsive movements which are due to an action upon the nerve centers, the muscles remaining intact, the heart also being affected, as it is believed, by an action upon its motor ganglia. In mammals the chief symptoms produced by nickel are paralysis, with motor disturbance bearing some resemblance to chorea, with convulsions and great irritation of the gastro-intestinal tract, and a marked fall of the blood pressure, due to paralysis of the vasomotor center. Large doses of *nickel* seem, however, to be necessary for a toxic influence, and the use of nickel in culinary instruments appears to be entirely safe. Riché (*B. A. M.*, 1888), as the result of experiments made upon dogs and guinea-pigs, reaches the conclusion that nickel is not more poisonous than iron. Thus, a dog absorbed over five drachms of it in sixty days, and increased in weight. The results obtained by Riché have been confirmed in Germany by von Hamel Roos and by Schulz. (*P. J.*, Dec., 1887.)

Nickel Bromide.—*Nickelous Bromide*, $NiBr_2$, is a greenish-yellow powder, of a sharp, almost burning taste, freely soluble in water, and making a grass-green solution. It was first brought forward by J. M. da Costa as a remedy for *epilepsy* and kindred disorders, and its value has been confirmed by R. Leaman. (*Med. Gaz.*, April 18, 1885.) It has been physiologically investigated by H. A. Hare, who finds (*T. G.*, vol. ii, 297) that it is a powerful paralyzant to the spinal cord, the motor and sensory nerve trunks, and also to the voluntary muscle. In sufficient dose it causes immediate diastolic cardiac arrest. In smaller doses it lessens the arterial pressure by depressing the heart and the vasomotor center.

Dose, five to ten grains (0.3–0.6 Gm.).

Nickel Carbonate. *Nickelous Carbonate. Niccoli Carbonas.* $NiCO_3 + Ni(OH)_2$.—Made by precipitating the solution of a nickel salt with potassium carbonate. It is from pale green to dark green, of variable composition. At one time it was employed in *anemia* in *doses* of two grains (0.13 Gm.).

Nickel Carbonyl. *Carbonic Oxide Nickel. Nickel-Kohlenoxyd*, G. $Ni(CO)_4$.—This substance is of interest because of the toxicity of its vapors. (See A. Mittasch, *A. E. P. P.*, xlix, 367; *L. L.*, 1903, i). Langlois (*C. R. S. B.*, 1891), also McKendrick and Snodgrass (*B. M. J.*, June, 1891), have shown that it acts by being broken up in the body and yielding carbon dioxide to the hemoglobin. For physical properties and methods of preparation, see authors quoted.

Nickel Chloride. *Niccoli Chloridum. Nickelous Chloride.* $NiCl_2 + 6H_2O$.—A green, very deliquescent salt. The anhydrous chloride is yellow and sublimes in yellow scales, without melting.

Nickel Sulphate. *Niccoli Sulphas*, $NiSO_4.7H_2O$.—It is in the form of emerald-green crystals efflorescent in the air, soluble in three parts of water, but insoluble in alcohol and ether. It has a sweet, astringent taste. Simpson found this salt to act as a gentle tonic, useful in *migraine* in *doses* of from half a grain to one grain (0.032–0.065 Gm.) three times a day. In large doses it is liable to produce nausea and vomiting, especially when the stomach is empty. (See *Braithwaite's Retrospect*, xxvii, 446.) Kolipinski (*J. A. M. A.*, 1911, lvii) states that *nickel sulphate* has a strong parasiticidal effect, that in solutions from one to two per cent. it is a useful application in *impetigo contagiosa, tinea,* and other parasitic skin diseases.

Nicotine Salicylate. *Nicotinæ Salicylas.* $C_6H_4(OH)COOH.C_{10}H_{14}N_2$. *Eudermol.*—This substance occurs in colorless crystals, soluble in water and alcohol, fusing at 118° C. Under the name of *eudermol* a substance composed chiefly of lanolin, containing 0.1 per cent. *nicotine salicylate,* has been put upon the market and highly commended for the treatment of *scabies* and other parasitic diseases of the skin, also of *itching eczema.* Ointments containing a larger per cent. are said to be dangerous. (*Th. M.*, 1898.) The application of the ointment should be followed after some hours by a soap bath. L. C. Fettich has used the 1 per cent. lanolin ointment of nicotine salicylate in cases of *mange* of dogs. When the mange is of the acaridic variety the treatment should be assisted by baths containing 2 to 4 per cent. of potassium sulphide.

Nierenbergia Hippomanica Miers. *Cup-flower. Chus-chu.*—This solanaceous plant is the not infrequent source of poisoning to cattle in Argentine where it is a native. Laveuir and Sanchez (*J. P. C.*, 1907, xxvi) have isolated a poisonous alkaloid to which they give the name *nierenbergine.* Apparently this alkaloid resembles saponin in some of its properties. They were not able to find the glucoside *hippomanin* which had previously been reported.

Nigella. *Nigella sativa* L. *Nutmeg-flower. Small Fennel-flower. Faux Cumin,* Fr. *Schwarzkümmel,* G. (Fam. *Ranunculaceæ.*)—A small, annual plant, growing wild in Syria and the south of Europe, and cultivated in various parts of the world. The seeds, *semen nigellæ,* are ovate, somewhat compressed, from 2.5 to 3.5 mm. in length, and less than 2 mm. in thickness, usually three-cornered, with two sides flat and one convex, black or brown externally, white and oleaginous within, of a strong, agreeable, aromatic odor, like that of nutmegs, and a spicy, pungent taste. (*P. J.*, 1882, 681.) Their chief constituents are a volatile and a fixed oil (1.5 per cent. of the former and 35 per cent. of the latter), and an amorphous glucoside, *melanthin,* which is decomposed by diluted hydrochloric acid into *melanthigenin* and sugar. This seems to be an acid saponin and Schulz (*Arb. Pharmacol. Inst. Zu Dorhat,* 1892, xiv, 112) has shown that it is extremely poisonous, the fatal dose for the cat intravenously being 1.5 milligrammes. The *nigellin* of Reinsch does not seem to have been a pure substance. Rochebrune has found a powerful paralyzing alkaloid, to which he gives the name of *nigelline.* (*Toxicol. Africaine,* vol. i.). In India the seeds are considered as stimulant, diaphoretic, and emmenagogue, and are believed to increase the secretion of milk. They are also used as a condiment, and as a corrigent or adjuvant of purgative and tonic medicines. In the seeds of the *Nigella Damascena* L., Schneider (*Ph. Centralh.*, 1890, xxxi, p. 173) found an alkaloid which he called *damascenine,* $C_{10}H_{15}O_3N$, whose construction was studied by Pommerehne and Keller. (*A. Pharm.*, 1904, ccxlii, p. 295.) They were unable to find any alkaloid in *N. sativa.* (See also Ewins, *Tr. Chem. Soc.*, 1912, ci, 544.)

Nigrosine. *Aniline Black. Coupier's Blue.*—A series of blue to black dyes prepared by oxidizing various proportions of nitrobenzene, aniline and toluidine. The process is purely empirical and admits of great variation in the resulting product. It is used as a black dye and in the manufacture of aniline inks.

Ninhydrin. *Triketol.*—This is phenyl-1:2-triketo-cyclopropane hydrate. It occurs in the form of colorless, water-soluble crystals. It is not employed therapeutically, being used solely as a reagent to demonstrate the presence of albumen, peptone, polypeptid, and amino acids, especially in the diagnosis of pregnancy after Aberhalden's method.

Nirvanin. *Glycocaine.*—The *hydrochloride of diethylglycocoll-p-amido-o-oxybenzoic-methylester.* It occurs in colorless prismatic crystals, with a melting point of 185° C., affording a violet reaction with ferric chloride, and soluble in water.

Nirvanin has been brought forward as a local anesthetic, with a claim that it is only about one-tenth as toxic as cocaine, and is as effective as a local anesthetic. It is also alleged to be actively antiseptic, the 1 per cent. solution effectively preventing the growth of bacteria. The 5 per cent. solution placed in the eye produces a temporary irritation followed by lasting anesthesia. It has been used to a considerable extent as a substitute for cocaine in infiltration anesthesia, the strength of the solution used varying from one-tenth to one-third of 1 per cent. Nirvanin has also been used to a considerable extent in dentistry; eight grains (0.5 Gm.) are stated to have been given to an adult, hypodermically without the production of toxic symptoms. (Elsberg, *Ther. Prog.*, April, 1900.)

Nirvanol. *Phenyl-ethyl-hydantoxin.* — This should not be confounded with nirvanin (see above). In its chemical composition this compound is analogous to that of barbital, glycolyl-urea, however, being substituted for malonyl-urea. It occurs as a colorless, odorless, crystalline powder insoluble in water, but is usually employed in medicine in the form of its soluble sodium salt. It is intended as a hypnotic. Although a number of cases of poisoning by this agent have been reported, Gelma and Schwartz (*Paris Méd.*, 1922, xii, 162) have found it a powerful and satisfactory somnifacient. The *dose* is from five to ten grains (0.3 to 0.7 Gm.).

Nitrated Alcohols.—The following substances of the possible series of nitrated alcohols have been studied by J. B. Bradbury (*B. M. J.*, 1895, ii):

Methyl Nitrate, (CH_3NO_3), *Glycol (Ethylene) Dinitrate* $C_2H_4(NO_3)_2$, *Glycerol Trinitrate (Nitroglycerin)* $C_3H_5(NO_3)_3$, *Erythrol Tetranitrate* $C_4H_6(NO_3)_4$, *Arabinol Pentanitrate* $C_5H_7(NO_3)_5$, *Mannitol Hexanitrate* $C_6H_8(NO_3)_6$.

Of the group the first three are liquid. The others are crystalline, colorless solids, stable in the dark at a moderately low temperature, turning yellow and exploding when heated above 150° C., or percussed. Of slight solubility in water, soluble in alcohol and ether, responding when heated to the meta-phenylene-diamine test.

Bradbury has shown that all these substances have similar physiological action, differing among themselves and from amyl nitrite simply in the rapidity and fugaciousness of influence. Glycol dinitrate in one-hundredth-grain (0.0006 Gm.) *doses* markedly influences arterial tension in the human being, but its effect is not maintained longer than sixteen minutes. Erythrol and mannitol nitrates were found to be slow in action but of remarkable permanence and influence, their effect on the lower animals lasting more than four or five hours. Methyl nitrate was feeble and fugacious in its influence.

Both erythrol and mannitol nitrates have been used by Bradbury and others in *angina, aneurism, Raynaud's disease, asthma, headache,* and various other affections for which nitroglycerin has been employed. Erythrol nitrate, as more soluble, appears to be preferable to mannitol nitrate. It is less easily exploded than nitroglycerin, but great care must be practised in any attempt at powdering, as a very serious explosion has occurred from rubbing it in a mortar with sugar of milk. It is usually administered in tablet form in *doses* of one-half to two grains (0.03–0.12 Gm.). The *dose* of the 1 per cent. alcoholic solution of mannitol nitrate is one and a half fluidrachms (5.5 cc.).

Nitrobenzene. *Nitrobenzole. Oil of Mirbane.* $C_6H_5NO_2$.—*Nitrobenzene* is formed by the action of strong fuming nitric acid upon benzene,

$$C_6H_6 + HNO_3 = C_6H_5 + H_2O.$$

The product, after having been washed with water, is an oily, yellowish, intensely sweet liquid, with an odor like that of oil of bitter almond. Its sp. gr. is 1.186, and boiling point 209° C. It has become of commercial importance, being produced as an intermediate product in the manufacture of aniline oil, and, under the name of *artificial oil of bitter almonds,* or *oil of mirbane,* being employed for scenting soaps and pomades. Its use in articles of food and for flavoring, as a substitute for bitter almond oil, is properly forbidden under pure food regulation. For method of detecting nitrobenzene in oil of bitter almond, see *Oleum Amygdalæ* (Part I). It is of commercial importance, as being used in the manufacture of aniline.

In manufactories where nitrobenzene is made, headaches, with sleepiness, are not infrequently produced by inhalation of the fumes; much more serious poisoning is liable to occur, and there have been a number of deaths produced by nitrobenzene. The symptoms may come on almost immediately, or they may be delayed for some hours. According to Filehne (*A. E. P. P.*, Bd. ix), the slowness of action is chiefly dependent on the fact that nitrobenzene, when mixed with the contents of the stomach and intestines, is absorbed with very great slowness; for if the drug be injected directly into the blood of the rabbit, it produces death in convulsions in less than a minute. The first symptoms of poisoning are headache, with muscular weakness, and a peculiar bluish color of the face, and disturbance of consciousness. In the fully developed poisoning the whole surface of the body is a deep bluish color, and the mucous membranes a bluish-gray; the pupils are dilated; the muscular relaxation is complete, except that sometimes the jaw is rigidly set; consciousness is lost; respiration rapid, but shallow and irregular; pulse rapid and thready, or entirely absent. The urine contains urobilin, indican, and acetone. Recovery may occur, as in a case reported by Stevenson (*Guy's H. R.*, vol. xxi, 1876), after many hours of unconsciousness, the bluishness of the skin and the headache remaining for several hours longer. After death, the blood is of a deep chocolate brown.

There have been a number of cases of nitrobenzene poisoning recorded from its use for various purposes in the arts. Apparently it can be absorbed through the skin in sufficient quantity to cause poisoning as in the series of cases reported by Stifel (*J. A. M. A.*, 1919, lxxii, 395) from the use of shoe dye containing nitrobenzene. Poisoning has also been caused by inhalation of the vapors.

The symptoms of nitrobenzene poisoning are due in part to the action of the poison on the nerve centers and in part to its destructive effect upon the blood. After death the blood is found of a deep, chocolate-brown color similar to that of methemoglobin but there is some doubt as to whether the compound formed is methemoglobin or some other chemical compound as some authorities report a different spectrum from that of methemoglobin. Loeb and Fitz (*Am. J. M. S.*, 1921, clxi, 539) in two cases of human poisoning found a very striking reduction in the oxygen-carrying power of the blood. Not only is there change in the chemical composition of the hemoglobin but also actual destruction of the red blood cells. According to Caspar, death from prussic acid and nitrobenzene may be distinguished by the fact that when the body is left open for some hours, the odor of prussic acid leaves, while that of nitrobenzene persists. The minimum fatal dose is not known; according to Taylor, fifteen drops (0.75 cc.), taken by the mouth, have proved fatal, and in Stevenson's case, twenty-three minims (1.42 cc.), taken in seven doses, in forty-eight hours produced unconsciousness and respiratory arrest, so that death would probably have occurred if treatment had not been instant.

In the treatment of nitrobenzene poisoning the first thing is to prevent further absorption by washing out the stomach, or removing the patient into fresh air, or removing the poison from the skin, according to the source of its entrance. Remembering the reduced hemoglobin, the use of oxygen inhalations naturally suggests itself. Both Werner (*B. K. W.*, 1884, xxi) and Loeb and Fitz have reported remarkable results from venesection followed with transfusion of blood. Circulatory and respiratory stimulants such as strychnine and atropine should be used as required.

Dinitrobenzene, Dinitrobenzol. 1–3 $C_6H_4(NO_2)_2$.—On boiling benzene with fuming nitric acid, there is formed chiefly *metadinitrobenzene,* fusing at 90° C., with small amounts of the ortho and para compounds. By crystallizing out of alcohol, the meta compound can be obtained pure. Dinitrobenzene has attracted considerable attention on account of the number of cases of poisoning by it occurring among the workmen in aniline works. The symptoms are said to be jaundice, enlargement with tenderness of the liver, diarrhea with colorless stools, and dark brown urine in which dinitrobenzene can be located by the phenylenediamine test. The toxicology has been especially studied by Strassmann and Strecker (*Friedreich's Blätt. f. Gerich. Med. u. Sanitätspolizei,* Heft iv, 1896), who add to the symptoms already given, headache, a peculiar bluish discoloration of the face and general surface, a tendency to fainting, with excessive sweating, vomiting, fall of temperature, great muscular weakness, and finally collapse. It is noted also that in animals experimentally poisoned there has been destruction of the red blood corpuscles with consequent hemoglobinuria and wide-spread fatty degeneration.

According to White and Hay (*L. L.*, 1901, ii) chemically pure dinitrobenzene is less poisonous than the commercial substance which contains the mononitrobenzene because the latter acts as a solvent for the dinitrobenzene and increases its absorption through the skin. The fact that the dinitrobenzene is absorbed through the skin of the workmen is so generally recognized that in most commercial laboratories the workmen are required to wear specially close fitting clothing over the body and head, and to practise absolute cleanliness.

Nitro-Propiol.—*Ortho - nitro - phenyl - propiolic acid,* when heated with grape sugar in the presence of soda, forms indigo, according to the following equation:

$$2C_6H_4(NO_2).C \equiv C—COOH + 4H = C_{16}H_{10}N_2O_2 + 2CO_2 + 2H_2O$$

The formation of indigo is rendered evident by a blue coloration of the fluid. The compound therefore serves as a qualitative test for the glucose in urine. Von Gerhardt recommends the following method for carrying out the test: Place 10 to 15 drops of the urine under examination in a test tube, add one hundred and sixty minims (10 cc.) distilled water and a *nitro-propiol tablet,* and carefully heat the mixture for two to four minutes. In the presence of sugar the fluid first becomes green and subsequently intensely blue. This reaction is sufficiently sensitive to indicate with certainty 0.3 per cent. of sugar and possesses the advantage that it only takes place if grape sugar is actually present in the urine.

Nizin. *Zinc Sulphanilate.* $Zn[C_6H_4(NH_2)SO_3]_2 + 4H_2O$.—It is intended as an astringent and antiseptic injection in the treatment of chronic gonorrheal *urethritis.* It is recommended to be employed in about one-half per cent. aqueous solution.

Njimo Wood.—The wood of *Sarcocephalus esculentus* Afzel. (Fam. *Rubiaceæ*), known as *Njimo,* was introduced into Germany from the Cameroons with the statement that it had digestive properties similar to those of pepsin. Schulz (*Ph. Ztg.,* June 12, 1886), however, was unable to perceive any digestive action. The bark of this same plant called "Dundaki," according to Heckel and Schlagdenhauffen (*Compt. Rend.,* 1885, 69) contains an alkaloid, *dundakine.*

Nosophen. *Tetraiodophenolphthalein. Iodophen.* $C_{20}H_{10}I_4O_4$.—*Nosophen* is obtained by the action of iodine on solutions of phenolphthalein. It is an impalpable, yellowish-gray, odorless, tasteless powder, containing 61.7 per cent. of iodine in combination. It may be heated up to 220° C. without decomposition. It is insoluble in water and acids, soluble with difficulty in alcohol, glacial acetic acid, ether, and chloroform, but readily soluble in alkalies, with the last of which it forms salts from which it is easily freed at low temperature by carbon dioxide. In the presence of heat it liberates carbon dioxide from its alkaline salts. By virtue of its two hydroxyl groups, nosophen is an acid, readily soluble in alkalies with replacement of the hydrogen atoms of both hydroxyl groups by a metal. Three of the salts of nosophen have been put upon the market—the sodium salt (antinosine), the bismuth salt (eudoxine), and the mercury salt (apallagin).

Antinosine has the following formula:

$$(C_6H_2I_2ONa)_2C.O.C_6H_4O.$$

It is a dark blue, amorphous powder which is readily soluble in water and alcohol.

Eudoxine, $(C_6H_2I_2OBi_2)_3C.OC_6H_4O$, is a reddish-yellow, tasteless, odorless powder, insoluble in water, which is decomposed by alkalies into bismuth oxide and a soluble salt of tetra-iodophenol-phthalein. It contains 52.9 per cent. of iodine and 14.5 per cent. of bismuth.

Apallagin. Mercury Tetra-iodo-phenol-phthalein.—A gray powder which is recommended as a powerful antiseptic.

Medicinal Properties and Uses.—Nosophen and its derivatives are asserted to possess disinfectant and local alterative powers. Nosophen, itself, is used especially as a surgical dusting powder, the advantages over iodoform being claimed for it not only being due to its lack of odor but also that it is non-toxic. It has been especially recommended as a dusting powder in nasal and laryngeal conditions. It has also been used internally as an intestinal antiseptic in *doses* of 5 to 8 grains (0.32 to 0.5 Gm.).

For intestinal use, however, eudoxin is usually preferred because it combines the action of bismuth with that of nosophen. This compound is believed to be decomposed by the alkaline juices of the intestines, liberating its constituent parts, and is used in *diarrhea* and various gastric and intestinal inflammations. *Dose,* five to eight grains (0.3–0.5 Gm.).

Antinosine, being soluble, may be applied where a non-toxic, antiseptic wash is desired as in *gonorrhea, cystitis, otitis media* and the like. It is used in strengths ranging from ½ to 2 per cent.

Novaspirin. *Salicitrin. Methylene-citric-acid-ester of Salicylic Acid. N. N. R.* 1924.—This is a white, crystalline powder representing 62 per cent. of salicylic acid. It is almost insoluble in water, but dissolves readily in alkaline solutions or alcohol. Its melting point is 150° to 152° C. This substance is used for those various conditions in which aspirin has been found of service, such as acute and chronic *rheumatism, neuralgia,* etc. It is stated that it is better borne by the stomach than aspirin and less likely to produce excessive sweating and the other undesirable sequelæ sometimes seen after the older remedy. Lehmann (*D. M. W.,* 1907, No. 10) has found, however, that it is less powerful in its effects than aspirin, especially in acute *rheumatic fever.* Gresic (*K. T. W.,* 1908, No. 4) has found it also of service in the treatment of *asthma,* both to prevent and to relieve the paroxysms. It is incompatible with iron compounds and with acids or strongly acid salts. The *dose* of novaspirin is from ten to thirty grains (0.65–2 Gm.) three or four times a day or oftener if needed.

Noviform. *Tetrabrom-pyrocatechin-bismuth.*—This is a yellow, insoluble powder. It is used as a surgical dressing in much the same way that iodoform has been employed.

Nuclein. *Nucleinum. Nucleol.* $C_{29}H_{49}N_9P_3O_{22}$.—The term *nuclein* is applied to a group of substances containing proteins which possess a *nucleinic acid* group in their structure, $C_{40}H_{54}N_{14}O_{27}P_4$. These proteins are derived from tissues rich in cell nuclein. The nuclein, however, probably does not exist as such in the cell but is produced by decomposition of the nucleo-proteids. It may be separated by digesting the cells with artificial gastric juice by which means the investing protoplasm is dissolved leaving the nuclein unaffected. The term *pseudonucleins* or *paranucleins* is applied to a group of bodies somewhat resembling the real nucleins, which are produced by the peptic digestion of proteins containing phosphorus but not nucleinic acid. *Nucleinic,* or *nucleic acid,* may be obtained from nuclein by the action of alkalies or by tryptic digestion. It occurs as an amorphous, white powder, strongly acid in reaction, sparingly soluble in water, but readily soluble in alkalies, and insoluble in alcohol or ether.

When nuclein-containing foods are taken, the nuclein is partly separated but not destroyed by the gastric digestive juices. In the intestines, however, the nuclein is broken up and nucleic acid liberated. Some of this may be further destroyed in the intestines but the larger part is absorbed. The nuclein absorbed is partially eliminated as purin bodies—allantoin, uric acid, etc.—and probably in part broken up into urea. As an almost constant accompaniment of the introduction of nucleic acid into the system, whether from the ingestion of food rich in nuclein or from the parenteral absorption of nucleinic acid or its salts, there is a great increase in the number of white blood corpuscles. Renner (*Mitt. Grenz. M. C.*, 1905, xv, p. 89) has reported as high an increase in the number of leucocytes as 452 per cent., and several authors have noted more than double the number of normal. This leucocytosis is usually preceded by a hypoleucocytosis of six or eight hours' duration. Fox and Lynch (*A. J. M. S.*, 1917, cliii, 235, 571) were unable to maintain the leucocyte count high by repeated injections.

Nucleinic acid has a distinct bactericidal effect; according to Kossel 0.5 per cent. of nucleinic acid kills streptococci *in vitro* in two hours and staphylococci after six hours. As has been shown by Vaughan and confirmed by Parlavecchio (*A. K. C.*, 1909, xc) and others, nucleinic acid also possesses bacteriolytic properties and even precipitates bacterial toxalbumins and in the body increases the formation of agglutinins and alexins. Chantemesse (*B. A. M.*, 1907, lvii) and others have noted an increase in the opsonic index.

These effects of nuclein should tend to increase the bodily resistance to bacterial infections and the drug has consequently been largely used in the treatment of *septicemia, furunculosis, tuberculosis, diphtheria*, and other diseases of bacterial origin. While the clinical reports have not been uniformly flattering they have been sufficiently encouraging to justify the further trial of this remedy in infectious conditions. In addition to this it has been used to a lesser extent for its influence upon metabolism in *anemia, neurasthenia*, and similar diseases. Donath (*M. M. W.*, 1912) asserts that it is a useful drug in parasyphilitic diseases, such as *general paresis*. He injects from eight to fifteen grains (0.5–1.0 Gm.) of *sodium nucleinate*, in the form of a 10 per cent. solution, gradually increasing the *dose* to sixty to seventy-five grains (3.9–5.0 Gm.), or until there is a febrile reaction.

Nuclein is frequently used in the crude form as found in various foods, such as yeast (see *Cerevisia*). There are, however, a considerable number of proprietary preparations more or less purified. Some of these are as follows:

Nuclein from yeast, a grayish-white, amorphous powder, sparingly soluble in water, but soluble in alkaline solutions. *Dose*, eight grains (0.5 Gm.) four to six times a day.

Protonuclein.—This is stated by the manufacturers to be prepared from the lymphoid structures and glandular organs of the body. *Dose*, three to ten grains (0.2–0.65 Gm.).

Nucleol.—This is stated to be pure nuclein. It occurs as a white powder, readily soluble in water.

Neucleic Acid (*Nucleinic Acid*).—There are several varieties of nucleic acids, all related but differing somewhat in their exact chemical composition. They are insoluble in either water, alcohol or ether but form salts with the alkalies which are water-soluble. When pure they do not give the biuret reaction characteristic of the albumins.

Nucleinic acid from yeast is a white or grayish-white powder obtained from yeast nuclein; it is practically insoluble in water, but is readily soluble in alkalies. *Rhomnol* is a trade name for *nucleinic acid.*

The ordinary *dose* of nucleic acid is from one-half to two grains (0.03–0.06 Gm.).

Animal Nucleinic Acid.—A yellowish powder prepared from the thymus gland and other similar animal glands containing nuclein; it has almost the same solubility as nucleinic acid from yeast.

Sodium Nucleinate.—A yellowish-white powder prepared from nucleinic acid from yeast. It is readily soluble in water and contains approximately 4.5 per cent. of sodium.

Sodium Tritico-nucleinate. Sodium Nucleate from Wheat.—Another form of sodium nucleinate is prepared by treating the aqueous extract of the wheat germ with sodium chloride and hydrochloric acid; the precipitate formed is digested with pepsin, neutralized with sodium hydroxide and precipitated with alcohol. This is marketed in the form of an aqueous solution—*Liquor Sodii Tritico-nucleinate*—containing about 10 per cent. of the salt.

Quinine Nucleinate.—A yellowish-white powder, slightly soluble in water, rather more soluble in alcohol (50 per cent.) and in dilute glycerin. It contains 40 per cent. of quinine.

Copper Nucleinate, Cuprol.—Cuprol occurs as a greenish powder, soluble in water, containing about 6 per cent. of metal. It is used as an astringent application in all those cases in which the older copper salts have been employed. In *conjunctivitis* a 5 to 10 per cent. solution has been recommended.

Ferric Nucleinate. Ferrinol.—Ferrinol is a brown powder, freely soluble in water, containing about 6 per cent. of iron.

Mercury Nucleinate. Mercury Nucleide.—Two forms of this compound are known to medicine, the one a direct combination of mercury with nucleinic acid known as *mercurol*, and the other known as *levurargyre*, made by acting upon yeast with mercuric chloride.

Mercurol is a colorless or brownish-white powder, containing 10 per cent. of mercury, soluble in water with a weak alkaline reaction, and has been used both internally and locally as a substitute for corrosive sublimate, over which it has the advantage of not coagulating albumin. In *syphilis* from half to one grain (0.032–0.065 Gm.) of *mercurol* may be given hypodermically. Two grains (0.13 Gm.) are said to have produced salivation. Another preparation similar to mercurol is called *Rhomnogyre.*

Levurargyre.—*Nuclein mercurate* is a grayish-white powder, soluble in water, and unaffected in solution by hydrogen sulphide. It is given in the treatment of *syphilis*, usually hypodermically, in *doses* of one-sixth to one-half grain (0.010–0.032 Gm.).

Mercedan is a proprietary preparation asserted to be a mercury-sodium paranucleinate.

Argentic Nucleinate. Nargol. Silver Nucleinate.—This is a light, brownish-white powder, readily soluble in water, contains 10 per cent. of silver. It has been recommended as a local application in those conditions for which silver

UNIVERSITY OF ILLINOIS LIBRARY-CHEMISTRY

nitrate has been used. It may be used in solution up to 25 per cent. on most mucous membranes. The solution should be recently made, as it undergoes change after a few weeks.

Nymphæa.—The terms *water lily*, or *pond lily*, are popularly applied to two genera of the Fam. *Nymphæaceæ*, of which several species have been used more or less in medicine. These are aquatic perennial herbs with thick horizontal rootstocks and usually floating leaves and solitary showy flowers. The petals are numerous; in the Nymphæa small and stamen-like, in the Castalia large and white but gradually passing into stamens.

Castalia odorata (Dryand.) Woodv. and Wood (*Nymphæa odorata* Ait.) is popularly called *Sweet-scented Water Lily*, *Water Nymph* or *Water Cabbage*. It has large flowers which are deliciously fragrant; the numerous white petals, sometimes tinted with rose, afford an attractive contrast with the bright yellow of the stamens. The orbicular or reniform floating leaves are from four to twelve inches in diameter, green and shining above, purplish beneath. The plant grows in ponds and sluggish streams throughout the eastern United States. The root contains, according to Bigelow, large amounts of tannic and gallic acid. It was formerly used as an astringent in application in *sore-throat* and *leucorrhea*, also internally in *diarrhea*. The *dose* employed in the latter condition was about thirty grains (2 Gm.).

Castalia alba Presl. (*Nymphæa alba* L.); the European white water lily, was formerly official in the French Codex under the name of *Nenuphar blanc*. The root (*Rhizoma Nymphææ*) contains, according to Grüning (*A. Pharm.*, 1882), an alkaloid closely related to nupharine (see below) and several astringent principles including *nymphæatannic acid*. It was used not only as an astringent but was at one time supposed to possess anaphrodisiac properties. The flowers of this species were also recognized by the Codex. They are astringent and apparently also sedative, and were used locally in gonorrhea and leucorrhea.

In the seeds of the *Nymphæa lutea* L. (*Nuphar luteum* Sibth. and Smith), European *Yellow Pond Lily* or *Spatterdock*, Grüning (*A. J. P.*, 1883, 96) found an amorphous, bitter alkaloid, *nupharine*. The presence of this alkaloid has been confirmed by Goris and Crété (*J. Chem. S.*, 1910) who demonstrated its occurrence in the fresh rhizome. They assign to it the formula $C_{18}H_{24}O_2N_2$. The rhizome also yields a large amount of a tannin, *nuphar-tannic acid*, $C_{56}H_{56}O_{37}$. This, like the previous species, was attributed with power of allaying sexual irritability and used in spermatorrhea, as well as for its astringent effects in diarrhea.

Nyssa. *Nyssa aquatica* Marsh. *Tupelo. Sour Gum. Swamp Tupelo.* (Fam. *Cornaceæ.*)—A large tree growing in deep swamps in the Southern United States. The root, known as *Tupelo root*, has been recommended for surgical tents. (*A. J. P.*, 1883.)

Ochres.—These are native mixtures of argillaceous or calcareous earth with iron and manganese oxides, employed in painting. They are prepared for use by elutriation. The color of the *ochres* varies with the state of oxidation of the iron, and with the proportion which the iron bears to the other ingredients, and is sometimes artificially modified by the agency of heat. Several varieties are known in commerce under different names, according to their color or place of origin. Such are *brown ochre*, *yellow ochre*, *red ochre*, *Roman ochre*, which is of a brownish-yellow color, changing by heat to a purple-red, *Oxford ochre*, of a brownish-yellow color less deep than the Roman, and *French ochre*, which is yellow. The *Indian red*, from the Persian Gulf, and *Spanish brown* and *Venetian red* may also be ranked in this class of pigments. Sometimes ochres come in powder, and sometimes in hard masses known as *stone ochres*.

Ocimum. *Ocimum Basilicum* L. *Basil. Sweet Basil. Grand Basilic*, Fr. *Basilienkraut*, G. (Fam. *Labiatæ.*)—An annual, aromatic plant, a native of India and Persia, and cultivated in Europe and in this country in gardens. It yields by distillation from 0.02 to 0.04 per cent. of a yellowish, volatile oil. The French and German oil have a penetrating odor resembling estragon, the Réunion has a camphor-like odor, a higher specific gravity and is dextrogyrate. Basil has the ordinary properties of the aromatic plants, and is used as a condiment. The seeds are said by Ainslie to be used in India in *gonorrhea*.

Œnanthe. *Œ. crocata* L. *Water Hemlock. Water Dropwort. Dead Tongue.*—A perennial, umbelliferous, aquatic, European plant, exceedingly poisonous both to man and inferior animals. The root, which has a sweetish not unpleasant taste, is sometimes eaten by mistake for other roots, often with fatal results. The symptoms produced are those of irritation of the stomach, besides failure of circulation, and great cerebral disturbance, indicated by giddiness, convulsions, and coma. (See *P. J.*, 1874, 202.) Externally applied, the root produces redness and irritation of the skin, with an eruption. It is said to be sometimes used empirically as a local remedy in *piles*. Other species of *Œnanthe* are poisonous, and the whole genus should be suspected. We have two or three indigenous species. In cases of poisoning, the stomach should be at once evacuated, and symptoms met as they arise. A peculiar resinoid principle, denominated *œnanthin*, has been found by Gerding in *Œnanthe fistulosa* L., the common water hemlock of Europe, of which half a grain (0.032 Gm.), given to an adult, produced long-continued irritation of the fauces, and a grain (0.065 Gm.), occasional vomiting. (See *A. J. P.*, xxi, 68.) Poehl (*A. E. P. P.*, 1895, xxxiv, p. 258) claimed to have isolated a toxic principle, to which he gave the name of *œnanthotoxin*, and assigned a formula $C_{17}H_{22}O_5$. Tutin, however (*P. J.*, Aug. 26, 1911), asserts that this body is not a pure principle but a mixture of neutral resins of unknown nature. He confirms the conclusions that the resin is an active poison. He also examined the tuberous roots of *O. crocata* and found *triacontane*, $C_{30}H_{62}$, and *hentriacontane*, $C_{31}H_{64}$. In the *P. J.*, vol. xvi, 357, is a paper by Henry William Jones upon the recognition of *Œ. crocata* in cases of suspected cattle poisoning; he found that the starch granules possessed characters which enabled him to distinguish the tubers from all others.

Œnanthe aquatica Lam. (*Œnanthe Phellandrium* Lam., *Phellandrium aquaticum* L.) *Fine-leaved Water Hemlock. Water Fennel. Fructus Phellandrii. Wasserfenchel*, G. *Phellandrie aquatique, Fenouil d'Eau*, Fr.—A biennial or perennial, umbelliferous, European water plant, the fresh leaves of which are said to be injurious to cattle, producing a kind of paralysis when eaten. By drying, they lose their deleterious properties. The cremocarp fruits are from 4 to 5 mm. in length (about 2 mm. broad), ovate-oblong, narrow above, somewhat compressed, marked with ten delicate ribs, and crowned with the remains of the calyx, and with the erect or reverted styles. Their color is yellowish-brown; their odor peculiar, strong, and disagreeable; their taste acrid and aromatic. Among their constituents is a volatile oil, upon which their aromatic flavor depends. C. Fronefield found a volatile alkaloid, analogous to, if not identical with, coniine. (*A. J. P.*, May, 1860, 211.) The ethereal oil of water fennel which is present to the extent of 1 to 2½ per cent. is a yellow liquid of strong, pleasant characteristic odor and burning taste. It has a sp. gr. of 0.85–0.89 and is dextrorotatory. It contains about 80 per cent. of phellandrene, $C_{10}H_{16}$. In overdoses the seeds produce vertigo, intoxication, and other narcotic effects. They have been used in chronic pectoral affections, such as *bronchitis, pulmonary consumption*, and *asthma;* also in *dyspepsia, intermittent fever*, obstinate *ulcers*, etc. The *dose* of the seeds, to commence with, is five or six grains (0.32–0.4 Gm.), so repeated as to amount to a drachm (3.9 Gm.) in twenty-four hours. They should be given in powder. *Dose*, of the alcoholic extract, three grains (0.2 Gm.). (*P. J.*, xii, 591.)

Œnothera. *Œnothera biennis* L. (*Onagra biennis* (L.) Scop.). *Evening Primrose. Night Willow-herb. Tree Primrose. Sun-drop. Onagre*, Fr. *Nachtkerze*, G. (Fam. *Onagraceæ*).—This is a native, annual, or biennial herb from one to several feet in height with more or less pubescent stem and lanceolate sessile leaves. The bright yellow flowers are composed of four petals and are one to two inches broad, usually opening about dusk of the evening.

The stem contains considerable tannin as well as mucilage.

Many years ago R. E. Griffith highly recommended a strong decoction of the plant in *tetter* and other skin diseases; an ointment made by boiling the herbage in lard or tallow was also used for the same purpose. Internally the drug was used as a gastro-intestinal demulcent and astringent; it was also attributed with antispasmodic properties and recommended in *whooping cough* and spasmodic *asthma. Dose*, of fluidextract, from a half to one fluidrachm (1.8–3.75 cc.). The ointment may be made by incorporating four ounces of the fluidextract in a pound of vaseline or lard.

Oil of Akee.—This is a yellow, non-drying, butter-like fat obtained from *Blighia sapida* Kon. (Fam. *Sapindaceæ*), a tree with paripinnate leaves and axillary racemes of white flowers, native to Guinea, but cultivated in Jamaica and South Florida. (*P. J.*, lxv, p. 691.)

Oil of Aleurites Triloba.—The *Aleurites triloba* Forst., or *Candle-Nut*, is a small tree belonging to the *Euphorbiaceæ.* It is widely diffused throughout the tropics. The fruit is a nut nearly as large as a walnut, consisting of a thick shell enclosing a kernel containing much protein and rich in oil, of which it is said to yield nearly one-half its weight by expression. The nuts strung together on the fibers of the palm leaf were formerly used in many Pacific islands as a substitute for candles. The oil has been long known in the various countries inhabited by the plant, being called in Jamaica *Spanish walnut oil*, in India *Belgaum walnut oil*, in Ceylon *kekune oil*, and in the Hawaiian Islands *kukui* oil. It is very fluid, of an amber color, without odor, of a nutty, pleasant taste, congealing at 0° C., insoluble in alcohol, readily saponifiable, "and very strongly drying." It is said to be a mild cathartic, acting like castor oil, but more promptly and without griping effects. (*J. P. C.*, 3e sér., xxiv, 228.) The *dose* is from one-half to one fluidounce (15–30 cc.), the smaller quantity generally answering. The cake left after the expression of the oil, given to a dog in the *dose* of about half an ounce (15 Gm.), produced no vomiting, but acted strongly as a purgative.

The oil of the *Tung Tree, Aleurites cordata* R. Br., is used to a large extent in the arts in China, under the name of *Chinese wood oil* or *tung oil.* (This must not be confounded with the Indian "oil of wood," see *Oil of Gurjun.*) It is prepared in China by a crude process of expression from the seeds which contain about 53 per cent. of oil. It occurs in two forms, *white oil*, a moderately thick, yellowish, transparent liquid, and the *black oil*, which is thick, black, and opaque; the latter is considered an inferior grade. Wood oil is used in China and Japan either as a direct application to wood or mixed with various substances, as lacquer varnish, or paint. Its most remarkable characteristic is its extraordinary drying property, which is said to exceed that of any known oil. When applied to wood it forms a resinous layer which is affirmed to be impermeable by water and ordinary solvents. Wood oil is largely imported into this country, where it is used in the making of varnishes and linoleum.

According to R. H. Davies, its sp. gr. at 15.5° C. is 0.94015; it remains liquid at –13.3° C. (*P. J.*, 1885, 636.) E. M. Holmes believes that the dark colored oil is made by boiling the kernels previous to expression, the cold drawn oil being colorless, inodorous, and nearly tasteless. The latter, according to Cloëz (*C. R. A. S.*, 1875, vol. lxxxi, 469), has the sp. gr. 0.9362, congeals at –18° C. to a transparent mass, solidifies rapidly when exposed to light in a closed vessel, and is the most drying oil known. (*C. D.*, May, 1902.) (See also *Proc. A. Ph. A.*, 1897, 677; and *Chem. News*, 1912, 14.) The official requirements of the Hong Kong Government, according to Browne (*Chem. News*, 1916, civ, 123), are: Spec. grav. (at 15° C.) not less than 0.9400; refractive index not less than 1.5204 at 15° C. He also gives the iodine value as 167 and saponification value as 191. It has been used in *ulcerations* and *skin diseases.* The seeds of the tung tree are used in China for killing rats, and are also affirmed to have emetic properties.

Oil of Anda.—A fixed oil procured by expression from the seeds of *Joannesia princeps* Vell. (*Anda gomesii* Juss.) (Fam. *Euphorbiaceæ.*) The bark of *J. princeps*, growing in the maritime provinces of Brazil, yields on being wounded a milky juice, which is said to be poisonous, and to be used for stupefying fish. The fruit, which is about as large as an apple, ash-colored, with two larger and two smaller ridges, encloses a two-celled nut, containing two seeds, about the size of a chestnut. Like the seeds of other euphorbiaceous plants, these are actively purgative, one seed, according to Martius, being the *dose* for a man. By expression these seeds yield a pale yellow, transparent oil, with little odor or taste, which is said to be used in Brazil for burning and painting. It has a sp. gr. 0.927, and in properties belongs to the class of semi-drying oils. (*P. J.*, 1905, 910.)

Mello Olliveria has found in it an alkaloid, *johannesine,* which Couty affirms to be inert. (*N. R.*, 1881, 260.) Norris, who tried the oil at the Pennsylvania Hospital, found it to operate on the bowels moderately in the *dose* of fifty drops (2.5 cc.), and copiously when more largely given. Maneol de Castro and other Brazilian physicians assert that in *doses* of from one-half to one fluidrachm (2–4 cc.) it acts in a manner very similar to castor oil, over which it has the great advantage of not being nauseous to the taste.

Oil of Anise Bark.—There has appeared in the European markets a bark, closely resembling Massoi bark, and is supposed to be derived from a species of *Illicium,* probably *I. parviflorum* Michaux, growing in Madagascar, which yields fully three and a half per cent. of a light, yellow oil, the odor of which slightly resembles safrol. It has a spicy taste, but is only slightly sweet. Its specific gravity is 0.969 at 15° C. Optical rotation –0° 46′ in a 100-mm. tube. Refractive index at 16° 1.52510. It contains a small quantity of ordinary anethol, but consists principally of the isomeric fluid anethol, the *methylchavicol* of Eykman, $CH_3O.C_6H_4.CH_2.CH:CH_2$.

Oil of Ben. *Behen Oil.*—This is a fixed oil extracted from the seeds of *Moringa arabica* Pers., and from *M. pterygosperma* Gaertn. (*M. Oleifera* Lam.) (Fam. *Moringaceæ*). It should not be confounded with oil of benne from *Sesamum indicum* L. (Fam. *Pedaliaceæ*).

These trees inhabit different parts of India, Arabia, Syria, etc., and have been introduced into the West Indies. The pungent taste of the root, which is sometimes eaten, has given the name of *horseradish tree* to *M. pterygosperma.* According to Henry Schachan (*Nouv. Rem.*, 1890), the tincture of the root is very actively diuretic and useful in cardiac *dropsy.* The oil of the seeds has long been known, though used in the arts rather than in medicine. It is prepared in Europe from the seeds brought from Egypt; and it would appear, from the statements of Macfadyen, that the idea generally prevailing that it is also extracted in the West Indies is incorrect. The oil has a sp. gr. of from 0.912 to 0.917; it solidifies at about 0° C.; indeed at 7° C. it begins to deposit the solid fats. It is inodorous, clear, and nearly colorless, and keeps long without becoming rancid. It resembles olive oil, and is used for similar purposes. Mérat and De Lens say that it is purgative; but most of the fixed oils are so in sufficient doses. According to Völcker, the oil contains palmitin, olein, and a peculiar fatty matter yielding an acid by saponification, which he names *benic* (or *behenic*) *acid* (*J. P. C.*, xvi, 77); this is one of the normal fatty acid series, possessing the formula $C_{22}H_{44}O_2$.

Oil of Callitris.—The genus *Callitris* (Fam. *Pinaceæ*) includes about 15 species of trees and shrubs which are native to Australia, New Caledonia and Africa. The wood of these plants is of great value as building timber because of the fact that it is not attacked by white ants. According to Baker and Smith ("Research on the Pine Trees of Australia," 1910) this protection is due to the presence of a phenol-like body, to which they give the name *callitrol.* The constitution of this substance which they have obtained from the wood of *C. glauca* R. Br., they have not as yet determined. Several of the Australian species yield a resin with the same properties as those of sandarac, but at present they have not been employed commercially as sources of this resin. The term *cypress pine* is applied in Australia to a number of these trees.

Oil of Cavete.—This is obtained from the seeds of the *Omphalea diandra* L. (*O. megacarpa* Hemsl.), Fam. *Euphorbiaceæ,* a Brazilian tree. It acts as a brisk cathartic in about three hours after taking, without pain or much continuance. (*P. J.*, 1918, ci, 95.) Cash (*J. P.*, 1911, xxxvi, p. 488) obtained from the *Omphalea triandra* L. seed, 56 per cent. of a pale yellow oil, with a specific gravity of 0.924, which, in doses of 0.5 Gm. exercised a cathartic and diuretic action. From the *O. diandra* L., he obtained an oil, somewhat darker in color than the preceding, which had a specific gravity of 0.922 and a saponification value of 190.3 and an iodine value of 119.7. This oil was also a cathartic and diuretic, although somewhat larger doses were required than in the oil from the *O. triandra* L. From the allied plant, *Garcia nutans* Rohr., he also obtained a cathartic oil.

Oil of Chione.—The bark of this West Indian tree, *Chione glabra* DC. (Fam. *Rubiaceæ*) yields on distillation 1.5 per cent. of a light yellow volatile oil, consisting chiefly of *o-oxyacetophenone,* C_6H_4-$OH.CO.CH_3$. A compound obtained synthetically from *o-nitrocinnamic acid* proved to be identical with that isolated from the oil. (See *J. Chem. S.*, vol. lxxv, 1899.)

Oil of Citronella.—There are a group of closely allied grasses which yield sweet-scented volatile oils. Of these volatile oils, which are sometimes spoken of collectively as *Indian Grass Oils,* there are at least five commercial varieties, namely, *Oils of Citronella, Lemon Grass, Palmarosa, Ginger Grass,* and of *Vetiver.* The botany of the sweet-scented grasses from which perfumery oils are obtained, has been somewhat confused. Stapf (see *Schim. Rep.*, April, 1907, p. 20) divides them into three groups, the *Cymbopogon, Andropogon* and *Vetiveria.*

Andropogon nardus L. (*Cymbopogon Nardus* Rendle) (Fam. *Gramineæ*) yields *citronella oil.* It grows in Ceylon, the Malaccan Peninsula, India and to some extent in tropical East Africa. There are two principal varieties, the one, *Lana Batu,* grows widely in Ceylon and yields an oil relatively poor in geraniol and is the principal source of the oil of commerce. The second variety, known as *Maha pangiri,* is generally cultivated in the Straits Settlements and in Java. This latter oil has a lower specific gravity, a lighter color and is claimed to be superior in quality.

Oil of citronella is produced in Ceylon, the Straits Settlements, close to Malabar, the Malay Peninsula and Java, the last named being the most highly esteemed. Oil of citronella is of a yellowish-green color, having a characteristic odor and pungent taste. Its sp. gr. is, according to Gildemeister and Hoffmann, 0.886–0.900. It mixes with alcohol in all proportions, and the test for purity given by Schimmel and Co. is based upon its behavior towards alcohol of 80 per cent: "One volume of the oil must form an absolutely clear solution with two, or at least two and a half, volumes of 80 per cent. alcohol at a temperature not below 20° C. A cloudy mixture indicates the presence of turpentine, certain fixed oils, and other essential oils which are sometimes used to adulterate it." The most important ingredients in this oil are *geraniol* and *citronellal* which together may make up as much as 93 per cent. of the oil. It is not used in medicine, but is largely used in the arts, for perfuming cheap soaps, especially so-called honey soap. An ointment containing 25 per cent. of the oil of citronella affords an excellent protection against the bites of mosquitoes and other insects.

Oil of lemon grass is official in the British Pharmacopœia (1914). (See *Oleum Graminis Citrati*, Part I.)

The *Palmarosa oil* is produced chiefly in India. It was formerly attributed to the *Cymbopogon Schoenanthus* Spreng. but Stapf (*Kew Bulletin*, No. 8, 1906) maintains that it is from a new species, *C. Martini* Stapf.

The *ginger grass oil* closely resembles palmarosa oil but contains a much smaller percentage of geraniol. It appears to be obtained from a variety of the *C. Martini* (Pearson, *P. J.*, 1916, xcvii, 251).

From the roots of the *vetiver* or *cus-cus grass, Vetiveria zizanoides* Stapf. (*A. muraticus* Retz), which grows in the island of Rèunion and in the Philippine Islands, is distilled a volatile oil. The odoriferous principle of this oil is at present unsettled. It has been attributed by Genivesse and Landlois to a peculiar alcohol which they named *vetivenol*, but this has been denied by Bacon. (*Philippine Journal of Science*, 1909, iv, p. 118.)

Various other allied grasses, such as the *Cymbopogon polyneuros* Stapf., or *Delft Grass*, and the *C. Coloratus* Stapf., etc., yield sweet-scented oils which have, however, not become commercially important.

Oil of Coconut. *Coconut Oil. Cocoanut Butter. Oleum Cocos*, P. G. *Oleum Cocois. Beurre de Coco*, Fr. *Kokosnussöl*, G.—This must not be confounded with the fixed oil of the chocolate nut, which is often called *cocoa butter.* (See *Oleum Theobromatis*, p. 797.) The substance here considered is the fixed oil of the coconut, which is the seed of the cocoanut palm, *Cocos nucifera* L., universally known as the *coconut tree*, or *cocoanut tree.* The oil is obtained either by expression or decoction, often by insolation—*i.e.*, exposing the rasped nuts to the heat of the tropical sun. It is of a fine white color, of the consistence of lard at ordinary temperatures, becoming solid, like suet, between 4.4° C. and 10° C., and liquid at about 26.7° C., of a bland taste, and a peculiar, not disagreeable odor. It is readily dissolved by alcohol. It contains large quantities of the glycerides of myristic and lauric acids, with smaller quantities of the glycerides of palmitic and oleic acids. It has also been found to contain several volatile acids, as caproic, caprylic, and capric acids. (Lewkowitsch, *Chemical Analyses of Oils, Fats, and Waxes*, 2d edition, 1898, 538.)

The oil has been used for various purposes in medicine and pharmacy. It has been employed as a substitute for cod liver oil—especially in the form of a proprietary preparation, *coco-olein*—a most unfortunate substitution as it contains neither the vitamines nor the peculiar fatty acids to which cod-liver oil owes its unique value. In Germany it has been used in pharmacy, to a considerable extent, as a substitute for lard, to which, according to Pettenkofer, it is preferable on account of its lesser tendency to rancidity, its more ready absorption when rubbed on the surface of the body, and its lesser liability to produce chemical changes in the substances with which it is associated. Besides, it takes up one-third more water, which is a useful quality when it is desirable to apply saline solutions externally. To prepare it for use, nothing more is ordinarily necessary than to melt it at a moderate heat, and strain it through linen. If colored, it may be digested with powdered animal charcoal, and subsequently filtered through paper. (*A. J. P.*, xxix, 331.) When chilled and pressed, a solid residue, which is *coco-stearin*, is obtained. This is extensively used as a substitute and adulterant of the genuine cocoa butter in the confectionery trade. Coconut oil is employed in the manufacture of soap, particularly of the transparent varieties, and the so-called "*marine soaps*" and *filled soaps;* it is also largely used for giving firmness and lathering qualities to the ordinary soap; this property also permits of the addition of a large quantity of water to the soap. Unfortunately, coconut oil soap is very apt to contain free caprylic acid; and the persistent rancid odor, resembling that of infants' vomit, left upon the skin after washing with its soap is an effectual bar to its very extended use. Besides the oil itself, the dried pulp of the coconut is sent to European and American markets in large amounts under the name of *copra.*

According to Parisi, the endocarp or meat of the coconut is a powerful tenicide. The patient should drink the milk and then eat the flesh of the nut. The coconut is said to be largely used in India as a vermifuge and the matter appears to have practical importance.

Powdered coconut shells were at one time largely used in America as an adulterant for spices. Their débris is readily recognized under the microscope by the peculiar elongated stone cells which have brownish-yellow walls and dark-brown contents.

Oil of Colza.—An oil expressed from the seed of *Brassica campestris* L. var. *oleifera* DC., or *field cabbage*, a cruciferous plant which is largely cultivated in France and Germany for the sake of this oil. *Colza oil* is used in Europe as a burning oil, as a lubricating oil, and, after purification by heating with starch, as a table oil. The raw oil has a sp. gr. of 0.915, and the refined oil 0.9136. Chilled to –4° C. stearin separates out, and at –6° C., it becomes a yellowish buttery mass. The oil contains the glycerides of stearic, *erucic* (or *brassic*) *acid*, $C_{22}H_{42}O_2$, and an acid isomeric with, but differing in some respects from, ordinary oleic acid. A similar oil is derived from *rape-seed* (*Brassica napus*). For analysis of commercial samples, see *C. D.*, 1894, 140.

Oil of Cypress. *Oleum Cupressi. N. N. R.* 1924.—An oil derived from the leaves and young branches of the Cypress tree, *Cupressus sempervirens* L. (Fam. *Pinaceæ*), an evergreen tree indigenous to S. Europe and W. Asia. It has a specific gravity of 0.88 to 0.89 at 15° C. and an optical rotation of + 4° to + 18°. It contains furfural, d-pinene, d-camphene, cymene, d-sylvestrene, d-terpineol, and esters of the same, l-cadinene and cypress camphor.

It has been strongly recommended by Bravo in *whooping cough;* it is used by sprinkling the oil upon the clothes, bed, etc., of the patient.

Winterseel (*In. Dis.*, Bonne, 1908) has studied *cypress oil* physiologically and finds that its action is similar to the other essential oils, but is of relatively low toxicity. When the reflexes are excited by spinal stimulants it acts as a depressant to the spinal cord. He confirms the favorable results of its inhalation in cases of *whooping cough.*

Oil of Dœgling. *Oleum Chœnoceti. Dœgling Oil. Dœgling Thran. Huile de Rorqual Rostré,* Fr.—The oil derived from the Norwegian whale, *Balœna rostrata,* is said by Gustave Guldberg to possess a lower specific gravity than any other animal oil (0.876 at 15° C.), and also remarkable penetrative properties. It is affirmed that if mixed in equal quantities with chloroform it carries the latter agent through the skin, and enables it to act as a local anesthetic in *pruritus, neuralgia,* etc. Mixed with wax, it is highly recommended as a basis for ointments by the same authority.

Oil of Egg Yolk.—A fatty oil obtained by expression from the yolks of fresh eggs. It has been used in lotions and as a popular remedy on the continent in the treatment of *corneal opacities.*

Thorpe's Dictionary gives the following composition and properties of egg oil: specific gravity, 0.9144; solidification point, 8°–10° C.; melting point, 22°–25° C.; acid value 1.2; saponification value 184.4–190.2; iodine value 68.5–81.6; insoluble fatty acids and unsaponifiable matter 95.16 per cent.

Benedikt states that the refractive index of egg oil is 1.4655 and that it gives the elaidin reaction. It is also stated that the oil obtained by expression differs from that extracted by solvents in that the latter contains cholesterol and lecithin.

Oil of Eulachon.—The fish known by the North Pacific Indians under the name of *Eulachon* or *Oulachon* and by the English as *Hoolakins* or *Candle fish,* the *Thaleichthys pacificus* of scientists, yields a great abundance of an oil which has been proposed as a substitute for cod liver oil. According to the editor of *N. R.* (1881, 356), this oil first begins to congeal and become opaque at −7° C., although authorities state that at ordinary temperatures it grows solid and lard-like. Specific gravity at 15.5° C., 0.907; mixed with one-half its volume of nitric acid, specific gravity 1.37, it develops a beautiful pink color which fades slowly to amber, and after standing fifteen hours it is considerably thickened and its color is changed to a deep amber of a reddish cast. It contains about 20 per cent. of palmitic and stearic acids, and 60 per cent. of oleic acid and 13 per cent. of an unsaponifiable substance, which resembles the similar constituent of sperm oil. (*T. G.*, Sept. 15, 1884.)

Oil of Euphorbia.—A fixed oil, obtained from the seeds of *Euphorbia Lathyris* L. (Fam. *Euphorbiaceœ*), or *Caper Spurge,* an annual plant naturalized in eastern U. S. A., though indigenous to Europe. It is often found near gardens and in cultivated fields, and is generally called *mole plant,* under the impression that moles avoid the ground where it grows. It is the *caper plant* of England. Like the other species of *Euphorbiaceœ,* it contains a milky juice which is extremely acrid, and the whole plant possesses the properties of a drastic purge; but the oil of the seeds is the only part used in medicine. This may be extracted by expression, or by the agency of alcohol or ether. In the first case, the bruised seeds are pressed in a canvas or linen bag, and the oil which escapes is purified by decanting it from the whitish flocculent matter which it deposits upon standing, and by subsequent filtration. By the other process, the bruised seeds are digested in alcohol, or macerated in ether, and the oil is obtained by filtering and evaporating the solution. According to Soubeiran, however, the oils obtained by these different processes are not identical. That procured by expression is probably the purest.

Oil of euphorbia is colorless, inodorous, and, when recent, nearly insipid; but it speedily becomes rancid, and acquires a dangerous acridity. Soubeiran has ascertained that it has a complex composition, containing, besides the pure oil, four distinct proximate principles. (*J. P. C.*, xxi, 259.) From 40 to 44 parts are obtained by expression from 100 of the seed. It is a powerful purge, but in *doses* of from five to ten drops is stated by continental physicians to act kindly upon the bowels. In this country, however, it has been found very uncertain in its effects, and very liable to cause vomiting. (*A. J. P.*, iv, 124.)

Oil of Gurjun. *Wood Oil. Gurjun Balsam.*—This oil must not be confounded with the *Chinese* wood oil, which is used as a varnish. (See *Oil of Aleurites*, p. 1515.) It is obtained from *Dipterocarpus turbinatus* Gaertn. f., and several other species of *Dipterocarpus* growing in East India (Fam. *Dipterocarpaceœ*), large trees which form forests in Pegu and other parts of Farther India. A large notch is cut in the trunk of the tree, between two and three feet from the ground, and a fire made so as to char the wound. The juice then begins to flow, and is received in suitable vessels. Every three or four weeks the charred surface is cut off and burned anew. A single tree sometimes yields forty gallons in a season. *D. tuberculatus* Roxb. yields a liquid known in Burma as *In oil,* which is sometimes sold as gurjun balsam. (*Proc. A. Ph., A.* 1913, 223.) It is at first turbid, but may be clarified either by filtration or deposition.

After filtration, it is a clear, dark brown liquid, of the sp. gr. 0.964 (Hanbury), and, in consistence, odor, and taste, bears a close resemblance to copaiba for which it was at one time substituted and in which it is still occasionally used as an adulterant.

Gurjun oil is soluble in two parts of alcohol, with the exception of a very small proportion of darkish flocculent matter, which subsides on standing. According to Lowe, it contains 65 per cent. of volatile oil, 34 of resin, and 1 of acetic acid and water. A characteristic property noticed by Lowe, by which it may be distinguished from copaiba, is that, when heated in a closed vial to 266° F., it becomes slightly turbid and coagulates, so that the vial may be inverted without changing the position of its contents, and this consistence is retained when the liquid cools. By a gentle heat with agitation the fluidity returns; but the liquid again coagulates if heated to 266° F. According to D. Brandis, this property of coagulation is characteristic of the wood oil from *D. alatus* Roxb. (*P. J.*, xxv), a wood oil which is further to be distinguished by the greenish opalescence of its surface.

Guibourt states that wood oil does not solidify, like copaiba, with one-sixteenth of magnesia, and the two separate on standing. (*J. P. C.*, xxx, 192.) According to De Vrij, with an equal volume of the wood oil, benzene forms a turbid mixture, from which, after a long time, a resinous matter is deposited in flocculi; with copaiba it forms a transparent solution.

The volatile oil from gurjun balsam is a yellow, somewhat thick liquid, of sp. gr. 0.915 to 0.930, and has at times a high optical rotation—viz., −35° to −130°. The oil boils in larger part at 255° to 256° C. and consists of a sesquiterpene, $C_{15}H_{24}$. With hydrochloric acid it yields a deep blue color. The resin left after distilling off the volatile oil is essentially *gurjunic acid,* $C_{22}H_{34}O_4$. This when purified dissolves readily in ether and strong alcohol, and slowly in benzene. It melts at 220° C. and congeals again at 180° C. Flückiger has also described a neutral resin from gurjun balsam, which is insoluble in caustic potash, fuses at 126° C., and is of the composition $C_{28}H_{46}O_2$. Flückiger (*A. Pharm.*, 1876, 420) noticed that wood oil may be recognized by the violet color it assumes if dissolved in twenty parts of carbon disulphide and mixed with a drop of a cold mixture of equal parts of concentrated sulphuric and nitric acids.

According to O'Shaughnessy, the oil of dipterocarpus is little inferior to copaiba in the diseases for which that medicine is employed. It has been used in *gonorrhea* given in the *dose* of a teaspoonful two or three times a day. It probably has a remedial influence similar to the different turpentines. The juice may be given in emulsion, in *doses* of from fifteeen to forty minims (0.9–2.5 cc.); the volatile oil from ten to twenty minims (0.6–1.3 cc.).

Oil of Jasmine.—This oil is obtained from the flowers of the *Spanish jasmine* (*Jasminum grandiflorum* L.). Alternate layers of the fresh flowers, and of cotton saturated with the oil of ben or other fixed oil, are exposed in a covered vessel to the warmth of the sun, the flowers being renewed until the oil becomes impregnated, when it is separated from the cotton by pressure. This method is necessary, as the flowers do not yield their aroma by distillation. According to Gildemeister and Hoffmann, jasmine oil contains 65 per cent. of benzyl acetate, and in addition linalyl acetate, benzyl alcohol, and linalool. The oil is used only as a perfume. W. H. Hall records (*M. S. Rep.*, Jan., 1861) the case of a child poisoned by the fruit of a jasmine, probably the common white species. The symptoms were coma, widely dilated pupil, and snoring respiration, with a cold pale surface, and slow and feeble pulse, followed by violent convulsions, with rigidity of the muscles about the head and throat.

Oil of Kuromoji.—Under this name there have entered commerce two fragrant Japanese oils—one, *Kouro motsi*, said to be obtained from the *Lindera sericea* Bl., and one, *Kuro matsi*, yielded by *Lindera umbellata* Thunb. (Fam. *Lauraceæ*). (See *Schim. Rep.*, 1904.)

Oil of Linaloe.—This volatile oil which is produced in Mexico, according to Seyffert (*Schim. Rep.*, Oct., 1907), is obtained from the wood of two species of *Bursera*, one of which is known in the Spanish as *Linaloe*, and the other as *Copal limon.* The latter tree is probably the *B. aloexylon* Engl. Better grades of this oil have a pleasant odor resembling a mixture of lemon and jasmine, while the poorer grades have a caraway-like odor. It is important in perfumery as the source of *linalyl acetate,* and is used as a substitute for oil of bergamot.

Oil of Maize. *Corn Oil.*—Our American maize or Indian corn yields a bright golden-yellow oil, of peculiar pleasant odor and taste. It is moderately thick, and has a sp. gr. at 15° C. of 0.916 to 0.924. It consists of olein and palmitin, and solidifies at –10° C. The oil is contained in the germs of the seed alone. Reckoned on the whole weight of the seeds the oil constitutes about 5 per cent., reckoned on the weight of the germ itself, after separation from the starchy body of the seed, the oil amounts to nearly 50 per cent. It is now being extensively produced in connection with the working of starch and glucose factories. It is used as a lubricant and for soap making, and as a substitute for cotton seed oil.

Oil of Neat's-foot. *Oleum Bubulum. Oleum Pedum Tauri. Axungia Pedum Tauri. Huile* (*Graisse*) *des Pieds du gros Bétail*, Fr. *Klauenöl, Ochsen Klauenfett*, G.—This formerly official oil is obtained by boiling for a long time the feet of the ox, previously deprived of hoofs. The fat and oil which rise to the surface are removed and introduced into a fresh portion of water, heated nearly to the boiling point. The impurities having subsided, the oil is drawn off, and, if required to be very pure, is again introduced into water, which is kept for twenty-four hours sufficiently warm to enable the fat which is mixed with the oil to separate from it. The liquid being then allowed to cool, the fat solidifies and the oil is removed and strained, or filtered through layers of small fragments of charcoal free from powder. The oil is clear and yellowish in color, of sp. gr. 0.916 at 15° C., and, when properly prepared, inodorous and of a bland taste. It thickens or congeals with great difficulty, and is, therefore, very useful for greasing machinery. It is also used for softening leather and in grinding metals. It was formerly given as a substitute for cod liver oil in scrofulous diseases but is no longer used in medicine.

Oil of Palm. *Palm Oil. Huile* (*Beurre*) *de Palme*, Fr. *Palmöl, Palmbutter*, G.—This highly valuable fixed oil is the product of *Elœis guineensis* Jacq., a palm growing on the western coast of Africa, and cultivated in the West Indies and South America. It is among the handsomest trees of its graceful family which flourish in the tropical regions of Africa. The oil is obtained by expression from the fruit. It is brought to this country chiefly from Liberia and other places on the African coast, although prepared also in the West Indies, Cayenne, and Brazil. It is not improbable that various species of *Palmaceæ* contribute to the supply of this article of commerce. At present the chief ports for its shipment are Cape Palmas and Lagos, prima and secunda Lagos being the choicest varieties.

Palm oil has the consistence of butter, a rich, orange-yellow color, a sweetish taste, and an agreeable odor, compared by some to that of violets, by others to that of the Florentine orris. By age and exposure it becomes rancid and of a pale yellow or nearly white color. It melts with the heat of the hand, and when perfectly fluid passes readily through blotting paper. Highly rectified alcohol dissolves it at common temperatures, and in ether it is soluble in all proportions. Its constituents are *tripalmitin* and *triolein*, $C_3H_5(C_{16}H_{31}O_2)_3$ and $C_3H_5(C_{18}H_{33}O_2)_3$. Palm oil undergoes more rapid spontaneous hydrolysis than any other fixed oil, as much as 75 per cent. of the oleic acid present being liberated within a few months. This makes the oil more easily saponifiable and may account for the preference given it by soapmakers in the days of empiric soap manufacture. Palm oil is said to be frequently imitated by a mixture of lard and suet, colored with turmeric, and scented with Florentine orris. It is much employed in the manufacture of toilet soap, which retains its pleasant odor. It is sometimes used to impart a yellow color to mixtures of fats or manufactured products, such as oleomargarine. In the latter case it is considered as an artificial coloring matter which necessitates the payment of ten cents per lb. additional tax. It is detected in the presence of other fats by a color reaction developed when sulphuric acid is added to a mixture of the suspected oil and an equal volume of acetic anhydride. This is known as Crampton-Simons test for palm oil, but it has been attacked by A. G. Gill (*J. I. E. C.*, 1917, p. 136) as being fallacious due not to a specific substance present in palm oil only, but to the presence of *carotin*, which is present in butter and some other constituents likely to be normally present in oleomargarine, to which this test is usually applied for the purpose of detecting the palm oil as an added coloring matter. Subsequently the method was improved and now consists of two separate tests, both of which must be positive. As now recommended it is carried out as follows:—Preparation of Sample: The sample should be kept in a cool dark place until tested, as exposure to light and air or the presence of water, alcohol, ether or similar reagents, interferes with the tests. Immediately before testing, the sample is filtered as quickly as possible at a temperature not exceeding 70° C. First Test: Dissolve 100 cc. of the fat in 300 cc. of petroleum ether and shake out with 50 cc. of a 0.5 per cent. potassium hydroxide solution. Draw off the aqueous layer, make distinctly acid with hydrochloric acid and shake out with 10 cc. of pure carbon tetrachloride. Separate the carbon tetrachloride solution, transfer a portion to a porcelain crucible, add 2 cc. of a mixture of one part colorless, crystallized phenol and two parts of carbon tetrachloride, then 5 drops of hydrobromic acid (sp. gr. 1.19) and mix by gentle agitation. The almost immediate development of a bluish-green color is indicative of palm oil. Second Test (usually preferred): Shake out 10 cc. of the melted and filtered fat with an equal volume of colorless, chemically pure, acetic anhydride, add 1 drop of sulphuric acid (sp. gr. 1.53) and shake the mixture for a few seconds longer. If palm oil is present the lower layer, on settling, will be found to be colored blue with a tint of green. The color in this as well as in the preceding test is transient.

Oil of Patchouli.—The genuine oil is obtained from *Pogostemon Patchouli* Pellet (*P. Heyneanus* Benth.) (Fam. *Labiatæ*), a plant cultivated in the Straits Settlements and in Penang. The plant has also been cultivated in the West Indies and in Paraguay. A small amount of oil is also obtained from *Microtæna cymosa* Prain, a plant cultivated in the mountainous districts of Assam. The patchouli herb is sometimes dried and sent into commerce. It is not infrequently adulterated with a number of other plants, the latter being present to the extent of 80 per cent. The oil as found in commerce is of two kinds. The best is that distilled in the East in the neighborhood of the patchouli plantations, from selected fresh leaves; the other kind is distilled in Europe from imported leaves; the latter often arrive in a more or less damaged condition, and are frequently adulterated. *Oil of patchouli* is a thick, brownish-yellow oil with a green tint and was shown by Gladstone to contain cœrulein, the blue compound found in oils of absinthium, matricaria, etc. The oil has the sp. gr. 0.970–0.990 at 15° C., and is lævorotatory. Rodie states that the odor improves by age and hence perfumers prefer the older oils. It deposits a solid, *patchouli alcohol*, $C_{15}H_{26}O$, which crystallizes in hexagonal prisms, melts at 56° C., and boils at 206° C., while cadinene, $C_{15}H_{24}$, remains; oil of cedar and oil of cubeb are frequently used to adulterate the oil. They may be detected by fractional distillation. Oil of patchouli is used in perfumery mainly for its valuable property of conferring upon other odors lasting qualities; its characteristic and persistent odor when uncombined is usually not popular among Caucasians.

Oil of Perilla.—This valuable oil is produced from seed of the *Perilla ocymoides* L., an Asiatic mint commonly grown in Japan and Korea. The oil is used in Japan in the manufacture of paints, paper umbrellas, and for similar purposes for which boiled linseed oil is used in the United States. It is claimed that it is superior to the latter for use in paints. It is also used as a food stuff.

Oil of Turtle. *Turtle Oil.*—In South America an oil is prepared from the eggs of turtles, and in the Seychelle Islands and in Jamaica from the fat of the turtle itself. These oils are said to be of equal value with cod liver oil for strumous persons and others in whom the nutritive processes are defective. (See *P. J.*, vol. xv, 573.) C. E. Sage examined *Turtle oil* as sold in London drug auctions and found the sp. gr. 0.919 at 25° C. The oil was yellow and semi-solid, having an odor of beef-drippings. (*C. D.*, 1906, 691.)

Oil of Ylang Ylang. *Cananga Oil. Oleum Anonæ. Oleum Unonæ.*—This is a volatile oil obtained from the flowers of *Cananga odorata* Hook. f. and Thoms (Fam. *Anonaceæ*), a large tree inhabiting most parts of Southern Asia; the oil from the Philippine Islands is especially esteemed. According to Schimmel & Co. (*Schim. Rep.*, April, 1897), it contains pinene, linalool, geraniol, esters of acetic and benzoic acids, cadinene, and para-cresol-methyl ester. It is used only as a perfume. The so-called *Macassar hair oil* is said to be a solution of it in coconut oil. (See *A. J. P.*, 1881, 123; also *A. J. P.*, 1893, 529.)

Ointment of Casein. *Unguentum Caseini Unna. Caseinsalbe*, G.—Prof. Francis Hemm quotes Dr. Unna's formula for casein ointment as follows: Take milk from which the cream or fat has been entirely removed and curdle it by the addition of rennet at a temperature of 30° to 40° C. Collect the coagulum and wash freely with cold water until the washings are no longer acid. Dry carefully and reduce to powder. Dissolve 34.5 parts of caustic potassium hydroxide and 8.5 parts of caustic sodium hydroxide in 5000 parts of water and dissolve 1400 parts of casein in this solution. Now add 700 parts of glycerin and 50 parts of phenol, and when dissolved incorporate 2100 parts of white petrolatum and 50 parts of zinc oxide and finally enough water to make 10,000 parts. (*M. B. D.*, 1906, 192.) It has the consistence of thick cream, is incompatible with acids and acid salts, but mercury, tar, balsam of Peru, zinc oxide, resorcinol, pyrogallol, and ichthyol may be incorporated with it. Certain forms of casein creams are known as rolling creams because when rubbed over the surface of the skin they take the dirt out of the pores by rolling up into small particles which can be brushed off. They are extensively used as cosmetics.

Ointment of Cucumber. *Cucumber Ointment.*—Emollient ointments prepared from the common cucumber (fruit of *Cucumis sativus* L., Fam. *Cucurbitaceæ*), were formerly considerably employed in irritated states of the skin. They have been largely superseded by non-fatty cosmetics. Several formulas for cucumber ointments are given in the *U. S. D.*, 20th ed., p. 1524.

The most frequently used preparation of cucumber at the present time is the cosmetic preparation known as *cucumber jelly,* which is used as a soothing application in roughness of the skin, etc. It consists of a jelly of tragacanth, quince seed, or some similar mucilaginous drug flavored with cucumber juice which imparts to the preparation a characteristic odor.

Olibanum. *Thus. Oliban, Encens,* Fr. *Weihrauch,* G.—*Olibanum,* the *frankincense* of the ancients, was erroneously ascribed by Linnæus to *Juniperus phœnicea* L. (*J. lycia* L.), but really is derived from several species of *Boswellia,* viz., *B. Carterii* Birdw. (furnishes what is known as *Luban Bedowi* or *Luban Sheheri*), and *B. Frereana* Birdw. (furnishes *Luban Meyeti* or *Luban Matti*). These are small trees of the Family *Burderaceæ,* growing in Somaliland and Arabia. They contain schizogenous gum-oleo-resin reservoirs in this bark. The natives incise the bark and collect the gum resin as soon as this exudation has dried. The drug is carried to Aden and thence to Bombay from which it enters commerce. It appears that the resin of *B. papyrifera* Hochst. is not gathered at all. The product of *B. serrata* Roxb. (known as *Salaigugul*) is not sent into general commerce, but is employed medicinally only in India.

The Arabian or African frankincense is in the form of yellowish tears, and irregular, reddish lumps or agglutinated masses. The tears are generally small, oblong, ovoid, clavate or pyriform, brittle, with a dull and waxy fracture, softening in the mouth, and bearing some resemblance to mastic, from which, however, they differ in their want of transparency. The odor is aromatic, balsamic; the taste slightly bitter. When triturated with water, the drug forms a milky emulsion. The reddish masses soften in the hand, have a stronger taste and odor than the tears, and are often mixed with fragments of bark and small crystals of calcium carbonate which are visible under the microscope.

The Indian frankincense, or olibanum, consists chiefly of yellowish, somewhat translucent, roundish tears, larger than those of the African, and generally covered with a whitish powder produced by friction. It has a balsamic resinous odor, and an acrid, bitterish, somewhat aromatic taste. When chewed it softens in the mouth, adheres to the teeth, and partially dissolves in the saliva, which it renders milky. It burns with a brilliant flame and a fragrant odor. Triturated with water, it forms a milky, imperfect solution. Alcohol dissolves nearly three-fourths of it, and the tincture is transparent.

Tschirch (*Harze und Harzbehälter,* 1900, p. 253) found in olibanum: resins 65 per cent.; volatile oil 6 per cent.; water soluble gum, 20 per cent.; bassorin, 6–8 per cent.; plant residue, 2–4 per cent. The resins were composed of *boswellic acid,* $C_{32}H_{52}O_4$, a resin acid of which well crystallized salts were obtained, and *olibanoresin,* $C_{14}H_{22}O$, a neutral resin. In the essential oil Wallach identified 1-pinene and dipentene, while the chemists of Schimmel & Co. found in addition phellandrene.

Olibanum is stimulant like the other gum-resins, but is now very seldom used internally. Delioux has obtained advantage from the inhalation of its fumes, when heated, in chronic *bronchitis* and *laryngitis.* (*B. G. T.*, Fév. 28, 1861.) It is chiefly employed for fumigation and in unofficial plasters. *Dose,* fifteen grains (1.0 Gm.), which may be increased to a drachm (3.9 Gm.) or more.

Canadian olibanum is reported by Karl Dieterich to be an American substitute for olibanum, which formerly came into the drug market from Hamburg. Its melting point is 77–78° C. Thus occupies a place about midway between Canadian olibanum or gum thus. It is a valuable American pine resin, which, however, containing no gum and therefore is not a gum resin. (*Ph. Centralh.*, 1912, 652–654.)

Omorol.—A compound of albumin and silver. It is a yellow powder, said to represent 10 per cent. of silver. It is insoluble in water, but soluble in physiological saline solution, and in the various body fluids. This silver compound is used as an antiseptic in the treatment of *catarrhs* of various mucous membranes, such as *pharyngitis, conjunctivitis,* etc., and also for its antiseptic influence on infected *wounds* and old *ulcers.* It is claimed that it is non-irritating and because of its relative insolubility the powerfully antiseptic effect is much more persistent than the ordinary preparations of silver. Viett (*Med. Klin.*, 1906, p. 436) has found it useful in the treatment of *diphtheria;* he dusts a finely powdered preparation on the infected area for one or two hours after previous cleansing of the throat with a gargle.

Onion. *Cepa.*—The bulb of *Allium Cepa* L. (Fam. *Liliaceæ.*) Fourcroy and Vauquelin obtained from the ordinary onion a white, acrid, volatile oil containing sulphur; also albumen, much uncrystallizable sugar and mucilage, phosphoric acid, both free and combined with lime, acetic acid, calcium citrate, and lignin. The expressed juice is susceptible of the vinous fermentation. The oil is essentially the same in chemical composition as the oil of *Allium sativum* L., and consists largely of allyl sulphide, $(C_3H_5)_2S$. (See *A. Pharm.*, 1892, 434.) Perkin and Hummel found *quercetin* in the outer skin of onion bulbs, and the skins have been used in dyeing.

The onion is sometimes used in domestic medicine as an expectorant in subacute *bronchitis,* and the onion poultice is sometimes employed as a mild irritant.

Ononis. *Radix Oncnidis. Rest Harrow. Ononis spinosa* L. (Fam. *Leguminosæ*).—This common European plant has the root more or less flattened, twisted and slightly branched; from 10 to 60 cm. in length and 1 to 2 cm. in thickness; externally it is grayish-brown, deeply wrinkled; the odor resembles that of licorice, the taste being sweetish, mucilaginous, afterward bitter. Kobert (*Pharm. Weekblad.*, 1918, lv, 49) has found in the ononis two saponins closely related to glycyrrhizin, one of which was previously described by Reinsch under the name of *ononin. Onocerin,* a di-secondary alcohol, $C_{26}H_{42}(OH)_2$, was isolated by Thoms, who proposed to change its name to *onocol.* (*A. Pharm.*, 1897, 28.) Cow (*A. E. P. P.*, 1912, lxix, p. 393) has found that in the dog, the aqueous extract of *ononis* exercises a diuretic effect approaching in power that of juniper, which conclusion has been clinically confirmed by Breitenstein. It also contains tannin.

Ophioxylon. *Radix mustelæ. Rauwolfia serpentina* Benth. (*Ophioxylon serpentinum* L.) (Fam. *Apocynaceæ.*)—In the root of this plant, which is used in East India as a purge and anthelmintic, Wefers-Bettink found a yellow crystalline principle, *ophioxylin*, melting at 72° C., and possessing the formula $C_{16}H_{12}O_6$; also a volatile oil. (*A. J. P.*, 1890.) It is widely used in India as an antidote against bites of serpents, stings of insects, etc.

Opopanax.—A concrete juice or oleo-gum-resin of *Opopanax chironium* Kch. (*Pastinaca Opopanax* L.) (Fam. *Umbelliferæ*), a plant closely allied to the common *parsnip*. It is a native of the Levant, and grows wild in the south of France, Italy and Greece. When the base of the stem is wounded, a juice exudes, which, when dried in the sun, constitutes the *opopanax* of commerce. Some authors state that it is obtained from the root. A warm climate appears necessary for the perfection of the juice, as that which has been collected from the plant in France, though similar to opopanax, is of inferior quality. The drug is brought from Turkey.

It is sometimes in tears, but usually in irregular lumps or fragments, of a reddish-yellow color, speckled with white on the outside, paler within, and when broken, exhibiting white pieces intermingled with the mass. Its odor is strong, peculiar, and unpleasant, its taste bitter and acrid. Its sp. gr. is 1.622. It is inflammable, burning with a bright flame. It is a gum-resin, with an admixture of other ingredients in small proportion. Tschirch found opopanax to consist of resin, 19 per cent.; ethereal oil, 6.5 per cent.; gum and plant tissues, 70 per cent.; water and loss, 4.5 per cent. (*A. Pharm.*, 1895, 209.) Schimmel states that the oil consists of an alcohol with a sesquiterpene as the chief constituent. (*Schim. Rep.*, 1904, 67.) Water by trituration dissolves about one-half of the gum-resin, forming an opaque milky emulsion, which deposits resinous matter on standing, and becomes yellowish. Both alcohol and water distilled from it retain its flavor; but only a very minute proportion of oil can be obtained in a separate state. Opopanax was formerly employed, as an antispasmodic and deobstruent, in *hypochondriasis, hysteria, asthma*, and chronic visceral affections, and as an emmenagogue; but it is now scarcely ever used. *Dose*, ten to thirty grains (0.65–2.0 Gm.).

Optochin. *Numoquin. Ethylhydrocupreine.*—$C_{21}H_{28}O_2N_2$. Under the name of *Cuprea Bark* the bark of the *Remijia pedunculata* Triana and the *R. purdieana* Triana, trees closely allied to the cinchonas, were at one time used in medicine. They contain a number of the cinchona alkaloids including quinine, quinidine, cinchonine and a related alkaloid, *cupreine*. Quinine is a methyl cinchonine while cupreine is hydroxy-cinchonine. The base is a white or faint yellowish amorphous powder with a bitter taste, practically insoluble in water but easily soluble in alcohol or ether. It forms a crystalline hydrochloride which dissolves in twice its weight of water or in 5 parts of alcohol.

Ethylhydrocupreine was shown by Morgenroth (*B. K. W.*, 1910 and 1911) to have specific germicidal powers against the pneumococcus and has been used both in true *pneumonia* and various local pneumococcus infections. While its general antibacterial effects are comparatively feeble Schiemann and Ischaivara (*Z. Hyg.*, 1914, lxxvii, 49) found that in the strengths of one part in 400,000 it kills the pneumococcus even in the presence of blood serum. These results, however, have been contradicted by Bedell (*J. A. M. A.*, 1920, lxxv, 928) who found that although in more concentrated solutions it was pneumococcicidal, in 1/400,000 it actually stimulated the growth of the pneumococcus. Although Waetzhold (*Ther. Geg.*, 1915, lvi, 262) and others reported favorably on its clinical value in *pneumonia* more recent studies have thrown great doubt on its clinical usefulness for this purpose. Moore and Chesney (*A. I. M.*, 1918, xxi, 659) have used it in 75 cases of pneumonia and were unable to perceive any noteworthy therapeutic benefit. In 12 per cent. of the cases there was temporary amblyopia. Objection has been made to the conclusions of Moore and Chesney, however, on the ground that they used the hydrochloride instead of the base itself. It is asserted that when the base is given by the mouth a markedly pneumococcicidal effect is accomplished without serious danger to the patient. The present evidence indicates strongly that the toxicity of optochin for human beings is so high that it is unsafe to give doses large enough to influence pulmonary infections without serious danger to the patient. On the other hand, there is considerable evidence that in local infections, as *pneumococcus conjunctivitis*, the installation of a one or two per cent. solution of the soluble optochin hydrochloride is of real value. Kolmer (*J. Ex. M.*, 1921, xxxiii, 693) has recommended the intraspinal injection of ethylhydrocupreine hydrochloride in pneumococcic *meningitis*.

Because of its toxicity it is not safe to give more than 1.5 Gm. (23 grains) in 24 hours to the ordinary adult. This may be conveniently divided into 8 doses of 0.15 Gm. (2 grains) every three hours. Smith and Fantus (*J. P. Ex. T.*, 1916, viii, p. 53) report a study of its physiological action with a review of the literature. They find that it is decidedly more toxic to infusoria than corresponding solutions of quinine. It is also somewhat more poisonous to animals, its toxicity for white mice as compared to quinine being as 7 to 5. As an antipyretic it is less efficient than quinine. When given to frogs in large doses it causes first exaggerated reflexes followed by paralysis of the peripheral nerves. They state that quinine produces the same symptoms. In mammals it causes motor weakness with exaggeration of reflexes and death from respiratory failure. In large quantities it depresses the heart but has less effect on the circulation than quinine. In solutions of more than 1 per cent. optochin is irritant to the conjunctiva, and later anesthetic. Recently it has been found by Liefmann (*Th. M.*, 1915, xxix, p. 260) to cure *malaria* which had resisted quinine. Two compounds closely related to optochin have been introduced as surgical antiseptics. These are the *isoamyl-hydrocupreine* known by the trade name of *eukupin*, and the *isoctyl-hydrocupreine* called *vuzin*. They are used in the form of their di-hydrochlorides. Bruhn (*Th. M.*, Dec., 1919) has found that the Gram positive bacteria—which include streptococci, staphylococci, pneumococci, diphtheria bacilli, etc.—are killed by these compounds in as dilute solution as one part in 10,000 but that even a 1 to 1000 solution is unable to restrain the multiplication of other bacteria.

Eukupin also possesses local anesthetic properties. The combination of this with its antiseptic influence makes it a valuable local application in *cancerous ulcers, carbuncles* and other painful infections. It is claimed to be especially efficacious for the sterilization of *diphtheria* carriers and meningococcus carriers. It has been used to a slight extent internally as a substitute for quinine in *malaria* and *influenza*. For internal use the base itself is recommended in *doses* of three to four grains (0.2–0.25 Gm.) every 3 or 4 hours. For local application the soluble dihydrochloride may be employed in strengths of 0.5 to 1 per cent. solution.

Opuntia. *Opuntia vulgaris* Mill. (Fam. *Cactaceæ.*) *Prickly Pear. Barberry Fig. Indian Fig. Figue de Barbarie*, Fr. *Indische Feige*, G.—A common cactus composed of flattened, prickly or spinose jointed stems, and occurring in sandy soil from Nantucket to South Carolina. For analyses of fruit of this cactus, see *A. J. P.*, 1884, 3, and 1896, 170.

Orange Red. *Orange Mineral. Sandix.*—Red lead oxide, prepared by calcining lead carbonate. It is of a lighter color than *minium*, and is used as a pigment.

Orcin. *Dihydroxytoluene. Dihydroxymethylbenzene. Orcinol.* $C_6H_3(CH_3)(OH)_2.[1:3:5]$.—The U. S. IX recognized this among the reagents and described it as in "monoclinic prisms, white with a reddish tint, which fuse at about 58° to 60° C. Orcin has an intensely sweet and astringent taste; very soluble in hot water, less soluble in cold water, readily soluble in alcohol or ether. The anhydrous substance fuses between 106° and 108° C. Anhydrous crystals are deposited from an ether solution. When exposed to light or air the crystals assume a reddish-brown color. The addition of a few drops of ferric chloride T.S. to an aqueous solution of orcin (1 in 20) produces a deep blue color. Warm 10 mils of an aqueous solution of orcin (1 in 10) with 10 mils of sodium hydroxide T.S. and add a few drops of chloroform; the solution assumes a purple-red color, then bright red, and, after diluting with distilled water, shows an intense, greenish-yellow fluorescence. Aqueous solutions of orcin (1 in 20) tested separately do not yield precipitates upon the addition of test solutions of either mercuric chloride, cupric sulphate, tannic acid or lead acetate; with basic lead acetate T.S., a white precipitate is obtained (characteristic of *resorcinol derivatives*)." *U. S. IX.*

It also gave an assay process requiring not less than 85 per cent. of anhydrous orcin.

Orcin is said to resemble resorcinol in its local action and to be useful in the same class of skin diseases. A coloring matter obtained from *orcin* by the action of ammonia is known as *orcein*, $C_{28}H_{24}N_2O_7$. It is used in microscopic staining. According to J. Andeer (*Med. Chron.*, Dec., 1885), orcin is distinctly antiseptic, and in poisonous doses produces death by a direct action upon the heart muscle.

Oreodaphne. *Umbellularia californica* (Hook. et Arnott) Nutt. (Fam. *Lauraceæ.*)—The *California Bay Laurel* is an evergreen tree of considerable size, rather abundant throughout the State. Its wood is much prized on account of the beauty of its grain and its immunity from the attacks of insects. The leaves yield about 4 per cent. of a neutral, straw-colored, limpid, volatile oil, which has a warm camphoraceous taste and a pungent aromatic odor, resembling somewhat that of a mixture of oils of nutmeg and cardamom. It is soluble in 1000 parts of water, and in alcohol and ether in all proportions. It is said, when inhaled, to cause dizziness and headache. John P. Heamy, (*A. J. P.*, 1875, 105) finds it to consist of a pure hydrocarbon, sp. gr. 0.894, boiling at 175° C., and an oxygenated, pungent portion which boils at 210° C. This he calls *oreodaphnol. Oreodaphene* was obtained by distilling oreodaphnol with glacial phosphoric acid. For the reactions, see Heamy's paper.

Orexin. *Phenzoline. Cedrarine. Tannexin. Phenyldihydroquinazoline Hydrochloride.* $C_{14}H_{12}N_2.(C_{14}H_{10}O_9)$.—A complex derivative of quinoline. It forms colorless, odorless, lustrous crystals with bitter, pungent taste, freely soluble in hot water. *Orexin* was first brought forward by F. Penzolt as a stomachic. It appears to be practically free from toxic properties, two grains of it per pound not being sufficient to kill a rabbit. It appears to be a very active remedy in those cases of failure of appetite in which simple bitters are indicated, and to be contra-indicated by hyperacidity of the stomach, gastric catarrh and gastric ulcer.

The *tannate* is affirmed to be more efficient than the hydrochloride, which salt it has practically replaced in the market. The tannate is a yellowish powder, tasteless, odorless, insoluble in water, freely soluble in acid solutions. It is very highly praised in all forms of *atonic dyspepsia, loss of appetite* in convalescence, and similar conditions. It is affirmed also to be very useful in the treatment of *vomiting*, following the use of narcotics, such as opium, chloroform, etc. It is chemically incompatible with iron salts. It is best administered in the form of powder, five to ten grains (0.3–0.7 Gm.) given in capsules, one to two hours before meals.

Organotherapeutic Extracts. *Endocrines.*—The use of the extracts of various organs as medicinal agents is one of the oldest known therapeutic measures. Thus, Pliny mentions the use of the brains of animals in the treatment of *jaundice*, and it is probable that this drug was used also by the ancient Egyptians. The modern use of organic extracts may be dated from the investigations of Brown-Sequard. (*A. de P.*, 1889, p. 51.) Since this time extracts of nearly every portion of the body have been tested therapeutically. From many of these extracts there is no reason to expect any beneficial influence in diseased conditions. On the other hand, it is impossible to deny that many of the glandular organs of the body deliver their secretions directly into the blood stream, and that these secretions are essential for the maintenance of health and it is *a priori* not unreasonable to expect that the artificial administration of these secretions will have a beneficial influence in certain diseased conditions. It is among the last group of drugs that *opotherapy* finds a justification for its existence. Two of these organs of internal secretion have achieved so fixed a place in medicine as to have received official recognition, namely, the suprarenal capsule and the thyroid gland. Although the pancreas probably also delivers an internal secretion, the pancreatin of the Pharmacopœia represents an external and not an internal secretion of the pancreatic gland. There are some which have firmly established their claims, although not yet included in the U. S. P., but the great mass of them are still in the experimental stage. The fact that attention is paid to the following preparations does not imply the opinion that they are proper endocrine organs, but merely that they are of sufficient commercial or scientific interest to deserve mention.

Cerebrin. Cerebrum Siccum.—The dried *brain* substance has been used by Babes and others (*K. T. W.*, 1900) in the treatment of *neurasthenia*, *insanity* and *epilepsy*. The treatment, however, has no scientific foundation. Wassermann (*B. K. W.*, 1898, p. 4) has shown that an emulsion of the brain is capable of neutralizing the tetanus toxin. It has subsequently been shown also that this holds true for strychnine and morphine and is probably due to its cholesterin content (see under *Cholesterin*). On this evidence an emulsion of the dried brain substance has been used in the treatment of *tetanus* and *rabies*. (Kowalski, *K. T. W.*, 1900, No. 5.) The *dose* of the dried brain substance is 30 to 60 grains (2–4 Gm.).

Ciliary Body. Corpus Ciliaræ.—The extract of the ciliary body, as well as the *vitreous body* has been used in sympathetic *ophthalmia* by Dor and by Wecker. (*Annals d'Oculistique*, August, 1902.) *Oculin* is a name applied to a glycerin extract of the ciliary body and vitreous humor.

Kidneys. Renes Siccum.—There is considerable evidence that the kidneys supply an internal secretion, but that failure of this internal secretion is the cause of uremia, as claimed by some, has certainly not been established. Although a number of authors have claimed beneficial results from the administration of the kidney substance in *nephritis* and *uremia*, it is probable that the treatment is useless. The *dose* recommended is from four to fifteen grains (0.26–1.0 Gm.) several times daily. *Nephritin* is a proprietary extract of this class.

Hypophysis. N. N. R. 1924.—As described in Part I the hypophysis cerebri or *pituitary body* consists of a posterior lobe which is made up of tissue which seems to be related to the nervous system, and it is therefore improbable that it has any secreting function. The *anterior lobe*, however, is composed of glandular tissue and is generally regarded as one of the organs with an internal secretion. The hormone which is furnished by this gland to the blood is especially important in the young as it apparently controls the growth of the bony and sexual systems. A deficiency of pituitary secretion in the young leads to dwarfism, failure of development of the sex organs, deposition of fat and often mental sluggishness. An excessive activity of the gland leads to gigantism (or in adults acromegaly), sexual precocity, and overgrowth of hair.

As a drug the extract of the anterior lobe of the pituitary gland has been employed for the correction of those failures of growth which seem to be attributable to pituitary deficiency.

Tethelin is a lipoid isolated by T. B. Robertson in 1916 and by him believed to be the growth controlling principle of the anterior lobe (see *A. J. P.*, 1919, xci, p. 349).

The dose of the desiccated anterior lobe of the pituitary is from one to five grains (0.06–0.3 Gm.).

Insulin.—It has long been known that destruction of the islands of Langerhans in the *pancreas* caused an increase in the blood sugar and the appearance of glucose in the urine. It is generally acknowledged that most, if not all, cases of diabetes mellitus are due to pancreatic disease. Various extracts of pancreas have been therefore tested in the treatment of diabetes but without any brilliant success. In 1922, Banting and Best (*J. Lab. Clin. M.*, 1922, vii, 251) evolved the hypothesis that the islands of Langerhans secreted a hormone which was essential for the metabolism of sugar and that the reason of the failure of previous pancreatic extracts was that the digestive enzymes present in these extracts destroyed the glycolytic hormone; and that if they could find a means of bringing about degeneration of the enzyme-secreting portions of the pancreas without affecting the islands of Langerhans it would be possible to prepare an active glycolytic extract. This they accomplished by ligation of the pancreatic ducts which led to atrophy of the pancreatic cells. From such glands they prepared an extract which, in normal animals, greatly increases the combustion of sugar and leads, therefore, to a reduction in the amount of glucose in the blood. In sufficient dose the blood sugar may be reduced below the necessary minimum and fatal effects follow.

Animal experimentation and numerous clinical trials have established beyond cavil the power of insulin to increase the metabolism of sugar in most cases of *diabetes mellitus*. This increased carbohydrate combustion has led, in the great majority of patients, to the reduction of the glykemia to normal limits, to the consequent disappearance of sugar from the urine and the subsidence of all clinical manifestations of the diabetes. Many of these patients are able, under the insulin treatment, to utilize a diet containing a normal percentage of carbohydrates without the occurrence of glycosuria. On the other hand, it must be remembered that the use of this extract simply provides the system with an absent hormone; it has no effect in restoring health to the diseased cells of the pancreas. In other words, it is not properly to be regarded as a curative agent as it does not tend towards a restitution of normal function. Just as in the case of cretinism it is necessary to continue the use of thyroid indefinitely, so in these cases of diabetes the complete withdrawal of the insulin is followed by a return of the carbohydrate intolerance. It has been found clinically, however, that after a few weeks' treatment with insulin the dose employed may be very greatly reduced; in other words, there is a partial recovery of normal pancreatic power just as has been observed frequently from the ordinary dietetic treatment. Banting, Campbell and Fletcher (*B. M. J.*, January 6, 1923, p. 8) and others, have shown that even in diabetic coma it may bring about, not merely a reduction in the excessive glucose in the blood, but also a restoration of the normal alkalinity of the body and consequent recovery in apparently morbid cases of acidosis. Strouse and Schultz have found it of great value in the treatment of various *infections*, either local or systemic, occurring in diabetic patients. Thalhimer (*J. A. M. A.*, 1924, lxxxii, 692) has found it of service in nondiabetic *acidosis* and the *vomiting* of pregnancy.

While insulin must be regarded as a very important addition to our remedial agents it must not be forgotten that improperly used, it is equally potent for injurious or even fatal effects. Too large doses may lead to dangerous and probably fatal reduction in the percentage of blood sugar. Fortunately, this reduction is signalized by very marked symptoms before it reaches fatal proportions and can be promptly relieved by the administration of available carbohydrate such as glucose. The symptoms of dangerous reduction of the blood sugar are weakness and a sense of fatigue, with extreme hunger and nervous restlessness; the most characteristic but somewhat later symptom is profuse sweating usually accompanied with tremors and followed by unconsciousness.

A remedy so potent for both good and evil as insulin is clinically useless unless the dose can be standardized. In the absence of definite knowledge of its chemical composition the present standardization of insulin is a physiological one based upon the amount required to effect glycolysis in the rabbit and the dose is expressed in units. One unit is one-third of the amount required to reduce the blood sugar to less than 0.045 per cent. in a rabbit of two kilogrammes weight that has been previously starved for 24 hours. This unit is known as the H unit. In 1923 a new unit, designated by the letter U and representing a 40 per cent. increase of strength, was introduced. For details of the method of testing insulin see *A. J. Phys.*, lxii, p. 162 and Voegtlin & Dunn, *U. S. Pub. Health Rep.*, August 3, 1923. The ordinary beginning *dose* is from 10 to 30 units daily, which must be given hypodermically or intramuscularly. In severe cases, with proper control by quantitative determinations of the blood sugar, much larger doses may be employed for short periods of time. In any case it is important that its use be regulated by frequent examinations of the urine or, better yet, estimations of the blood sugar.

(For references to the literature on this subject see Allen, *J. Metabolic Research*, 1922, ii, p. 125, and Joslin, *J. A. M. A.*, 1923, lxxx, p. 1581, and an editorial in *J. A. M. A.*, June 2, 1923, p. 1618.)

The chemical nature of the glycolytic hormones, as well as the mode of its action in the body, are entirely unknown. It is interesting to note, however, that a number of investigators have prepared extracts from a variety of sources, including yeast, raw potato juice, etc. (See Thalhimer and Perry, *J. A. M. A.*, 1923, lxxx, p. 1614), which have an effect upon carbohydrate metabolism apparently similar to those of insulin.

Liver. Hepar Siccum.—Gilbert and Karno (*S. M.*, 1897, p. 184) believe that there is some substance in the liver which leads to a retention of the glycogen out of the blood in the liver, and that the administration of this substance is of benefit in the treatment of *diabetes*. Gyr asserts that the extract of the liver is also useful in *hepatic cirrhosis* (*R. M. S. R.*, June 20, 1908), and in *hemeralopia* by Roncagliolo (*Med. Klin.*, 1905, p. 909). The *dose* of the dried liver is one-half to one ounce (15–31 Gm.) per day.

Mammary Gland. Mammæ Siccatæ.—On the theory that there is some relation between the uterus and the mammary gland, the latter has been used by Shober (*Phila. M. J.*, Nov., 1899) and others, in the treatment of *menorrhagia, fibromata, dysmenorrhea*, etc. The *dose* of the dried gland is five to ten grains (0.32–0.65 Gm.) three times a day.

Ovaries. N. N. R. 1924.—That the ovaries deliver an internal secretion which while not essential to life, certainly modifies in some way metabolism, is almost universally accepted. One of the strongest proofs of this is seen in the symptoms which occur at the menopause or after double oöphorectomy. The *corpus luteum*, according to Ott and Scott (*Proc. of the Soc. of Exper. Biol. and Med.*, 1910, viii, p. 49), has a marked stimulating effect upon the mammary gland, but the ovarian substance when deprived of this was without such action. There is strong clinical evidence that the administration of the ovarian substance will at least temporarily relieve the symptoms seen at the menopause, whether the latter is natural or artificial. Richter (*D. M. W.*, 1899) has found that there is a marked increase in the fatty metabolism under the feeding of the ovarian substance. These investigations have been confirmed by Thumim. (*Ther. Geg.*, 1900, p. 451.)

The ovarian substance has also been used in the treatment of *neurasthenia* by Vidal (*Press. Med.*, 1900, p. 173) as well as in a host of other diseases in which there was much less likelihood of benefit following its administration. (For review of the literature, see Offergeld, *D. M. W.*, 1911, p. 1172.)

The *corpus luteum* has been used for various disturbances of *pregnancy* on the ground that these were due to the natural intermission in this function. Hirst (*J. A. M. A.*, 1921, lxxvi, 772) who has had excellent results with the extract of corpus luteum for the relief of the *vomiting* of pregnancy maintains that the cause of frequent failure after its oral administration is the destructive influence of the digestive secretions. He prefers to give it intravenously using 2 cc. (30 minims) of a solution which represents 0.4 Gm. (6 grains) of the dried gland twice daily for 4 doses. Taylor, however, objects to the intravenous injection and prefers to give the drug intramuscularly. He gives an extended review of the literature (*Pa. M. J.*, 1923, xxvi, 252). The corpus luteum has also been used in the treatment of menopausal disturbances and various menstrual disorders. Proprietary preparations of the ovarian substance are *glandnovin, ovadin, ovarial, ovarigen, oophorin, ovaron, lutein, ovariin* and *overaden*.

Dose, of desiccated ovarian substance, one to three grains (0.06–0.2 Gm.). The dried corpora lutea is given in *doses* of one to five grains (0.065–0.32 Gm.) two or three times a day.

Parotid Gland. Parotis Siccum. Glandula Parotidis.—Believing that there is some connection between the parotid and the sexual organs, Bell (*Ther. Woch.*, 1896, p. 659) has employed the parotid gland in the treatment of *dysmenorrhea, ovarian neuralgias*, and other disorders of the pelvic organs. The dried substance is usually administered in tablet form in *doses* of from one to three grains (0.065–0.2 Gm.) three times a day.

Parathyroids. N. N. R. 1924. *Glandula Parathyroidea.*—These are four small bodies growing near the lateral lobes of the thyroid gland. Because of their anatomical proximity it was at one time believed that their function in the body was similar to that of the thyroid body, but it is now known that these two organs are in no way physiologically connected. The parathyroid bodies, however, play some important rôle in the bodily metabolism. Although the view formerly held that their removal was certainly fatal has been shown to be incorrect, yet their extirpation gives rise to very violent symptoms which destroy life unless actively combated. The most prominent of these symptoms are violent tetanic convulsions and a marked reduction in the blood calcium. Some believe that the convulsions are due to the absorption of toxins from the intestines, while others believe that they are due to the withdrawal of lime salts from the nerve system. (See Vines, *B. M. J.*, 1922, i, 791.) Ott and Scott (*Amer. Med.*, 1910) have found that the parathyroid extract has a powerful diuretic influence. The dried parathyroid gland has been used in the treatment of *tetany.* (Loewenthal, *Med. Klin.*, 1907, p. 1012.) It has also been used by Meyer (*Ther. Geg.*, 1913, 354) and Berkley (*N. Y. M. J.*, Nov. 23, 1907) in treatment of *paralysis agitans.* The *dose* is one-tenth of a grain (0.006 Gm.) two or three times a day.

Spleen. Lien Siccus.—It can hardly be considered definitely established that the spleen furnishes any internal secretion. According to Danilewsky and Salensky (*A. G. P.*, 1895, p. 264), however, the subcutaneous injection of the splenic extract produces an increase in the percentage of hemoglobin, and in the number of red blood cells. It is also asserted that there is an increase in the number of the white corpuscles. It is possible that these effects are not due to any substance peculiar to the spleen, but to the nucleinic acid which it contains. Accordingly, the splenic extract has been used in the treatment of *anemias,* with more or less beneficial results. Leake and Bacon (*J. P. Ex. T.*, 1924, xxiii, 353) have shown that feeding splenic extract causes a marked increase in the number of red blood cells, but the effect is especially noteworthy if it is combined with simultaneous administration of bone marrow. Carpenter (*D. M. Ztg.*, 1907, p. 571) asserts that it has a specific action in *malaria.* H. C. Wood (*A. J. M. S.*, 1897, p. 511) has found it useful in *Graves's disease.* It has also been recommended in various forms of *insanity.* One of the difficulties in the use of this drug is to obtain a preparation which is active and yet will be borne by the stomach. The dried powder is given in *doses* of four to fifteen grains (0.26–1 Gm.) three times a day. It is doubtful, however, how far it entirely represents the drug. Under the name of *eurythrol,* an aqueous extract has been marketed. The *dose* of this is one to two teaspoonfuls, given generally in soup. *Lienaden* and *opo-lieninum* are proprietary preparations of spleen.

Suprarenals. Suprarenalum Siccum, U. S. IX, *Glandulæ suprarenales,* U. S. VIII. *Adrenals.*—The suprarenal glands are small organs found in all mammals, situated in the neighborhood of the kidney. They consist of an outer layer, or *cortex,* composed of tissue similar to that of the glandular organs and an inner layer—the medulla, which in its development and histology seems to be related to nerve tissue. The extirpation of these organs in the lower animals is almost invariably fatal within one or two days. Although the evidence is strong that this death is due to the destruction of the cortex rather than of the medulla (see Houssay and Lewis, *C. R. S. B.*, 1921, lxxxv, p. 1210) we know very little as to the precise function of this portion of the suprarenal bodies. The medullary part contains a nitrogenous body that has a very pronounced effect on the various functions of the system (see *Epinephrina*). There is considerable evidence that stimulation of the peripheral of the splanchnic nerve causes a discharge of epinephrine into the general circulation and many physiologists regard this substance as a true internal secretion.

The U. S. IX defined the dried suprarenals as: "The suprarenal glands of animals which are used for food by man, cleaned, dried, freed from fat, and powdered, and containing not less than 0.4 per cent. nor more than 0.6 per cent. of epinephrine, the active principle of the suprarenal gland. One part of Dried Suprarenals represents approximately 6 parts of fresh glands, free from fat. If assayed biologically one gramme of Dried Suprarenals contains the equivalent of ten milligrammes of lævo-methylamino-ethanol-catechol." *U. S. IX.* When freed of their fat and dried they may be pulverized. This powder is a "light yellowish-brown, amorphous powder, having a slight, characteristic odor; partially soluble in water. Dried Suprarenals contain not more than 7 per. cent. of moisture, and the yield of ash does not exceed 7 per cent.

"*Assay.*—Add 0.005 Gm. of finely powdered manganese dioxide and 10 mils of distilled water to 0.01 Gm. of Dried Suprarenals; thoroughly shake the mixture several times during one hour and filter. Compare the color of the filtrate in a test tube or in any convenient manner, with the color of cobaltous chloride T.S. and diluted gold chloride T.S. (see Reagents, Part III) combined as follows: Mix 1.85 mils of cobaltous chloride T.S. with 0.95 mil of diluted gold chloride T.S. and 7.2 mils of distilled water; the color corresponds to 0.2 per cent. of epinephrine in the filtrate obtained above; 2.95 mils of cobaltous chloride T.S. with 1.25 mils of diluted gold chloride T.S. and 5.8 mils of distilled water corresponds in color to 0.4 per cent. of epinephrine; 4.05 mils of cobaltous chloride T.S. with 1.35 mils of diluted gold chloride T.S. and 4.6 mils of distilled water corresponds in color to 0.6 per cent. of epinephrine; 5.15 mils of cobaltous chloride T.S. with 1.55 mils of diluted gold chloride T.S. and 3.3 mils of distilled water corresponds in color to 0.8 per cent. of epinephrine. The percentages of epinephrine indicated by the above color standards are based upon the maceration of 0.01 Gm. of the Dried Suprarenals in 10 mils of distilled water, as directed above, and filtering. In samples containing more than 0.8 per cent. of epinephrine, 0.005 Gm. of the Dried Suprarenals may be taken, in which case the percentage stated above, as indicated by the color standards, should be doubled. The standard color solutions keep unchanged, if sealed in glass tubes." *U. S. IX.*

It will be noted that the chemical and biological assays differed, the latter requiring the presence of 1 per cent. of active principle, the former only 0.5 per cent. How this discrepancy was to be reconciled surpasses conjecture.

Seidel and Fenger (*U. S. Hygienic Lab. Bull.* No. 100, 1914) have found that the percentage of epinephrine in the suprarenal gland of the beef runs distinctly higher than those of either sheep or swine, varying in the beef glands from 0.4 to 1 per cent., in hogs and sheep from 0.1 to 0.4.

Uses.—An aqueous solution of the dried suprarenals will produce all the effects described under *epinephrine* (see Part I), but because of its greater convenience the alkaloid is universally preferred. There are one or two conditions, however, in which the whole drug is to be preferred. Foremost among these is that syndrome known as *Addison's disease.* According to S. Solis-Cohen, the administration of the suprarenal gland by the mouth every two or three hours is sufficient to prevent the occurrence of the *asthmatic paroxysm.*

Dose, three to ten grains (0.2–0.65 Gm.).

Testicles. Testes Sicci. Orchic Substance.—The basis of the famous elixir of Brown-Sequard, *Liquor spermaticus,* was the fluid contained in the testicles. The persistent use of the various imitations and modifications of the *Brown-Sequard Elixir* would argue that it must possess some therapeutic virtue. It is claimed by those who use it that it has a powerful tonic effect, not merely improving the strength, but also exercising a beneficial influence upon the metabolism, so as to lead to a permanent augmentation of power. It has been recommended for *neurasthenia, diabetes, locomotor ataxia, arteriosclerosis,* and a large number of other chronic complaints.

The dried testicular substance is given in *doses* of from five to thirty grains (0.3–2 Gm.), but it is generally recommended as a liquid preparation, and that it should be given hypodermically. Among the preparations which contain testicular fluid as their important ingredient are the *succus e testibus paratus, orchidin, Hawley lymph, testaden, testidin* and *teston.*

A salt solution of the hydrochloride of the amine *spermin* ($C_5H_{14}N_2$), a normal constituent of the spermatic fluid is used as a nerve tonic and stimulant in a variety of infectious diseases, as *typhus, syphilis,* etc. *Dose,* subcutaneously, sixteen minims (1 cc.) of a two per cent. solution; by mouth, ten to thirty drops (0.6–1.8 cc.) of a four per cent. solution.

Thymus Gland. Glandula Thymi Sicca.—This body, which is the ordinary *sweet-bread,* is found only in young animals, disappearing as adult life comes on. Physiologists are not agreed to its exact importance or function. It appears to have some connection with the growth of bone and also of the formation of the white corpuscles of the blood. It has been used in medicine chiefly for two purposes, namely, in the treatment of *exophthalmic goiter,* and for the purpose of stimulating body growth in *rickets* and *ununited fracture.* It should be remarked that thymus contains a larger percentage of nuclein than any common food stuffs, and for this reason its use is generally forbidden to gouty patients. The *dose* of the fresh gland is from one drachm to half an ounce (2–15 Gm); of the dried gland from two to five grains (0.12–0.3 Gm.).

Bone Marrow. Medulla Ossium.—Leake (*J. P. Ex. T.,* 1923, xxii, 401) in experiments in human beings found that desiccated bone marrow caused an increase of about 15 per cent. in the number of red blood cells; when spleen substance was administered at the same time the increase was even greater. It has been used by Gullan (*Lancet,* 1907, p. 520), and others in the treatment of *pernicious anemia.* Gullan administered it by spreading the fresh red bone marrow on bread, which is taken at meal times. It is very prone to produce nausea. The *dose* of the fresh marrow is one to three ounces (31–93 Gm.); of the dried marrow two to five drachms (7.7–20 Gm.). *Opo-osslin* and *ossagen* are proprietary preparations made from bone-marrow.

Oridine.—*N. N. R.* 1925. This is the calcium salts of the iodized fatty acids of cotton seed oil analogous therefore to calcium iodobehenate. It occurs as a light brown powder almost odorless and tasteless, practically insoluble in water and only sparingly soluble in the ordinary organic solvents. It represents from 23 to 25 per cent. of iodine. It is used as a substitute for the alkaline iodides and presumably has the same advantages as the official calioben.

Origanum. *Wild Marjoram. Marjolaine sauvage,* Fr. *Wilder Majoran* (*Meiran*), G.—Two species of *Origanum* (Fam. *Labiatæ*) have been used in medicine. *O. marjorana* L. (*Majorana hortensis* Moensch) or *sweet marjoram,* and *O. vulgare* L., or common marjoram. The former, which is widely used as a seasoning herb, grows wild in Portugal and Andalusia, and is cultivated as a garden herb in other parts of Europe and in the United States. *Sweet marjoram* has a pleasant odor, and a warm, aromatic, bitterish taste, which it imparts to water and alcohol. By distillation with water it yields a volatile oil. It is tonic and gently excitant, but is used more as a condiment than as a medicine. In domestic practice its infusion is employed to hasten the tardy eruption in *measles* and other exanthematous diseases.

Sweet marjoram is a perennial herb indigenous to the Mediterranean region and Asia. In this country it grows along the roadsides, and in dry, stony fields and woods, from Pennsylvania to Virginia, and is in flower from June to October; but is not very abundant, and is seldom collected for use in the wild state.

The parts used consist of the dried leaves but parts of the flowering tops are usually admixed with these. Most of the drug is imported from France, Spain and Germany.

Sweet marjoram imported during recent years from Europe was found to be adulterated by mixing with it broken fragments of leaflets of the poisonous *Coriaria myrtifolia.* (See LaWall, *Proc. Penna. Pharm. Assoc.,* 1917, xl, 241.)

Two kinds of *oil of origanum* are now known commercially: the Trieste oil, of dark color and high specific gravity, and the Smyrna oil, of lighter color, lower specific gravity, and milder taste. The former contains from 60 to 85 per cent. of carvacrol, $C_{10}H_{14}O$, a trace of another phenol, and cymene, $C_{10}H_{14}$. The latter contains from 25 to 60 per cent. of carvacrol and, in addition, linalool and cymene. The specific gravity of the Trieste oil ranges from 0.94 to 0.98, while that of the Smyrna oil is from 0.915 to 0.945. (Gildemeister and Hoffmann, *Aetherische Oele,* pp. 813, 814; see also *Schim. Rep.,* 1913, 76.)

The *French oil of marjoram* is said to be distilled from *Clinopodium Nepeta* (L.) Kze. (*Calamintha Nepeta* Link. and Hoffm.). It is colorless, but gradually turns yellow on exposure. It is neutral in reaction, sp. gr. 0.904 at 16° C., and optical rotation $[a]_D = + 18° \ 39'$ in chloroform solution. On fractionating, three constituents were isolated, *lævo-pinene, calaminthone,* and *pulegone. Calaminthone* is a new ketone, $C_{10}H_{16}O$. (See *P. J.,* March, 1903.)

Origanum floribundum, of Algeria, yields largely of a volatile oil containing 25 per cent. of thymol. (*P. J.,* Feb., 1903.)

Oroxylon. *Oroxylon indicum* Vent. (Fam. *Bignoniaceæ.*)—This bark yielded by a tree indigenous to Southern Asia is said to be not only a tonic and astringent, useful in *diarrhea,* but also a powerful sudorific. A yellow crystalline substance, *oroxylin,* has been separated from the bark by Naylor and Chapman (*P. J.,* Sept., 1890), and from the seeds by Hooper (*P. J.,* vol. lxi). The seeds have been used in veterinary medicine.

Orpiment. *King's Yellow.* As_2S_3.—A native *arsenic trisulphide.* It is in masses of a brilliant lemon-yellow color, composed of flexible laminæ, and slightly translucent. It exists in various parts of the world, but is obtained for use from Persia and China. (Guibourt.) It is sometimes mixed with realgar, which gives it a reddish or orange hue. A similar sulphide may be made artificially by passing hydrogen sulphide through a solution of arsenic trioxide in hydrochloric acid or by fusing together equal parts of arsenic trioxide and sulphur. (Turner.) In Germany, according to Guibourt, it is prepared by subliming a mixture of these two substances. In this case, however, it retains a large portion of the acid undecomposed, and is therefore highly poisonous. Guibourt found a specimen which he examined to contain 94 per cent. of arsenic trioxide and only 6 per cent. of the trisulphide.

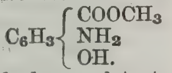
Orpiment is an ingredient of certain depilatories. *Atkinson's depilatory* is said to consist of one part of orpiment and six parts of quicklime, with some flour and a yellow coloring matter. (*Ann. Ch. Ph.*, xxxiii, 348.) But this arsenical sulphide is chiefly used in fireworks and as a pigment.

Orsudan. *Sodium 3-methyl-4-acetylaminophenylarsenate.*—This is soluble in three times its weight of water, and contains 25.4 per cent. of arsenic.

Orsudan has been brought forward as a means of obtaining the anti-syphilitic action of the organic compounds of arsenic. Although favorable results have been reported, the experience of Lane (*B. M. J.*, 1910, ii, p. 599), who reports a case of permanent total blindness following its use, would make one hesitate greatly before employing it. The *dose* ordinarily administered is ten grains (0.65 Gm.) deeply injected into the muscles on alternate days until ten doses have been given.

Orthoform. *Orthocaine.* *N. N. R.* 1924.

Methyl amino-paraoxybenzoate.



$$C_6H_3\begin{cases}COOCH_3\\NH_2\\OH.\end{cases}$$

This compound forms a white, odorless and tasteless powder, almost insoluble in water, easily soluble in alcohol, melting at 141°–143° C. It is sometimes called *orthoform-new* to distinguish it from a closely similar compound which was formerly used.

Orthoform was introduced into practical medicine by Einhorn and Heinz (*M. M. W.*, 1897). Its hydrochloride is soluble in water, but is so acid in its reaction as to interfere with its use.

The physiological action of orthoform is only so far made out as to show that, probably on account of its insolubility, it has very little influence upon the system whether given by the stomach or hypodermically, Heinz having found that ninety grains produce no distinct symptoms in the lower animals, and seven hundred grains have been applied to a facial ulcer in a week without injurious effect (*L. L.*, 1897); also, according to Neumayer (*M. M. W.*, xliv, 1897), sixty grains taken by a man in the course of a day produced no symptoms whatever, not even evidences of gastro-intestinal irritation.

The chief value of orthoform is as a local anesthetic. Because of its insolubility its field of usefulness is practically the same as that of benzocaine (see Part I). The studies of Sollmann (*J. P. Ex. T.*, 1919, xiii, 429) have shown that at least as far as the effects on mucous membranes are concerned, orthoform is decidedly the weaker. According to Neumayer, its local analgesic action is not accompanied by abolition of the sense of touch.

Orthoform has been widely employed to relieve the *pain* in various ulcerated conditions such as *tuberculosis, laryngitis, cancerous sores*, etc. In *keratitis* with ulceration, Boisseau commends an ointment made with one drachm each of lard and lanolin and twenty-four grains of orthoform. In many cases orthoform may also be added with advantage, on account of its anesthetic properties, to ointments containing medicinal substances. Böttcher (*B. K. W.*, 1919, lvi, 1084) recommends a 10 per cent. ointment in *pruritus vulvæ.*

Gustav Spiess found that insufflations into the posterior part of the pharynx may greatly alleviate the paroxysms of *whooping cough.*

Internally, orthoform in *doses* of eight grains (0.5 Gm.) has been used with asserted good results in *cancerous* and other *ulcerations of the stomach* and has been found useful in the treatment of *gastralgia.*

Externally, orthoform may be used either as a dusting powder, ointment or solution.

According to Yonge (*B. M. J.*, i, 1898), for many purposes the saturated solution of orthoform in collodion is most effective. In diseases of the larynx the parts may be sprayed with a solution of five grains of orthoform and fifty minims each of alcohol and water, which soon coats the diseased surface.

Orthoform has been believed to be actively antiseptic, but Lichtwitz and Sabrazes (*B. M.*, xi, 1897) found that bouillon saturated with it was still capable of serving as a culture medium. The antiseptic influence of orthoform is probably due to its decomposition by ulcerated surfaces.

Occasionally orthoform produces marked irritation and even violent inflammation at the seat of its application, and several cases have been reported in which it has produced sloughing, which has been compared to that caused by pure phenol. According to the majority of clinical reports, orthoform is of little value except as a local remedy, though relief has been claimed from it in the treatment of *syphilitic headaches.*

Doses of five to ten grains (0.32–0.65 Gm.) may be given three to four times a day.

Orthosiphon. *Orthosiphon stamineus* Benth. *Java Tea.* (Fam. *Labiatæ.*)—This drug occurs in commerce in the form of small, oval, finely toothed, green leaves, rolled up like tea. Van Itallie has discovered in it a volatile oil and a crystalline glucoside, *orthosiphonin*, and potassium salts. (*Ph. Ztg.*, Sept., 1886; see also *Répertoire de Pharm.*, 1887, 191.) It is said to be a powerful diuretic, and is highly recommended in *gravel*, and *ascites.* It has also been used in *diabetes.* The *dose* is from fifteen to thirty grains (1.0–2.0 Gm.) a day.

Ortizon. *Perhydrit, Peraquin.*—Under these names has been introduced a combination of hydrogen dioxide and urea containing about 35 per cent. of hydrogen dioxide. This occurs as a white crystalline powder without odor, permanent in dry air and soluble in 2.5 parts of water, the hydrogen dioxide being split off by solution. It is intended as a convenient method of carrying hydrogen dioxide for the preparation of solutions. Bactericidal properties of the solutions prepared from this compound have been used by Ungermann. (*Hyg. R.*, 1913, p. 1137.)

Osha Root.—This is the root of *Ligusticum filicinum* Wats. (Fam. *Umbelliferæ*), a perennial herb indigenous in Utah and neighboring States and known as *Colorado cough root.* It was formerly used as an expectorant. H. Haupt found in it an acid, *oshaic acid*, closely resembling angelic acid. (*A. J. P.*, 1867, 1868, 1873.)

Osmic Acid. *Osmium Tetroxide. Osmic Anhydride.* OsO_4.—A volatile, odorous, crystalline compound, produced by the action of nitrohydrochloric acid on osmium or either of its lower oxides.

Its vapor is very pungent and poisonous, attacking the eyes and respiratory organs. Claus recommends as an antidote to its action cautious inhalation of hydrogen sulphide. Osmic acid melts to a colorless liquid at 90° C., softening at a temperature of 35° C. It is slowly soluble in water; soluble in alcohol and ether; but these solutions are unstable, depositing black *osmic hydroxide*, $Os(OH)_4$. *Potassium osmate*, $K_2OsO_4 + 2H_2O$, is made by adding potassium hydroxide to an alcoholic solution of osmium tetroxide, and separating the crystals by careful evaporation. In the form of deep, garnet-red crystals, readily soluble in water, but decomposing when in solution or moist air; permanent in dry air. It is incompatible with organic substances, phosphorus, ferrous sulphate and iodides.

Osmic acid is used largely as a histological stain. We have no definite knowledge as to its influence upon the animal system when given in small doses. It has, however, been used internally especially in the form of potassium osmate in *rheumatic affections*, such as *sciatica*, and in *epilepsy*. The *dose* is one-sixtieth of a grain (0.0011 Gm.) at short intervals up to a daily dose of one-quarter of a grain (0.016 Gm.). In 1887 Stekoulis (*L. L.*, Aug. 13, 1887) suggested the injection along the course of the nerve trunks for the relief of *sciatica*. The method has been extended to include other painful diseases of the peripheral nerves, such as *tic doloureux*. According to Hammerschlag (*A. K. C.*, 1906, lxxix), while it generally gives temporary relief it rarely causes permanent cure. From five to fifteen minims (0.32 to 1 cc.) of a 1 to 2 per cent. solution are injected immediately into the nerve trunk. Auerbach (*Journ. of Laryngology and Rhinology*, June, 1891) recommends osmic acid for the destruction of morbid growths.

Ovogal. *N. N. R.* 1924.—This is a product obtained by the combination of bile acids with egg albumen. Alkalies dissolve *ovogal* with decomposition into its primal constituents. Ovogal is a yellowish-green powder, insoluble in water and acid solutions, but in the presence of alkalies it dissolves with decomposition. It therefore should not be prescribed in combination with alkalies.

It has long been well known that the salts of the bile are the most potent stimulants to hepatic secretion that we possess and this combination of cholic acid with albumin has been shown by Worner (*Med. Klin.*, 1906, p. 547) to increase the secretion of bile. The favorable results obtained by him in *intestinal dyspepsia, atonic constipation, acute* and *chronic catarrh of the biliary passages* has been confirmed by a number of authors. From ten to fifteen grains (0.65–1.0 Gm.) may be given four or five times a day. Rahn (*M. M. W.*, 1907, No. 10) proved the harmlessness of the drug by taking himself one and one-half teaspoonfuls without any evil results. It may be administered either as a dry powder or enclosed in capsules.

Oxalic Acid. *U. S.* Reagent (see Part III). *Acidum Oxalicum. Acide oxalique ou carboneux*, Fr. *Oxalsaure, Kleesaure*, G. $H_2C_2O_4.2H_2O = 126.05$.

This acid is found both in animals and vegetables. It is generated occasionally in disease, and it may be deposited in the bladder as calcium oxalate, forming the *mulberry calculus*. In vegetables, it occurs in a free state in the bristles of the chick pea (*Cicer arietinum* L., Fam. *Leguminosæ*), as an acid potassium oxalate in *Rumex Acetosa* L. (Fam. *Polygonaceæ*), or common sorrel, in *Oxalis Acetosella* L. (Fam. *Oxalidaceæ*), or wood sorrel, in *Chenopodium Quinoa* Willd. (Fam. *Chenopodiaceæ*), *Amaranthus caudatus* L. (Fam. *Amaranthaceæ*), *Mesembryanthemum crystallinum* L. (Fam. *Aizoidaceæ*), and in many other plants. It is said to be formed in the leaves. (*J. Chem. S.*, 1886.) Combined with calcium in microscopic crystalline forms, it is abundant in almost every portion of the vegetable kingdom.

Saccharomyces Hausenii has the property of producing a fermentation which forms oxalic acid out of sugar.

Many substances yield oxalic acid by the action of nitric acid, such as molasses, rice, potato starch, gum, wool, hair, silk, and many vegetable acids. This reaction was formerly the chief commercial source. For details of this process, see 15th edition *U. S. D.*, p. 90. The yield of oxalic acid from a given quantity of material has been much misunderstood. If properly treated with nitric acid, 100 lbs. of good sugar will yield from 125 to 130 lbs. of oxalic acid, and the same weight of molasses from 105 to 110 lbs.

The oxalic acid of commerce is now obtained by heating sawdust or wood shavings with a mixture of sodium hydroxide and potassium hydroxide. Sodium hydroxide alone will not generate the acid, and potassium hydroxide is too costly to be used by itself for the purpose; but Dale ascertained that, by mixing the two in the proportion of two molecules of sodium hydroxide to one of potassium hydroxide, the same or an even better result was obtained than from the latter alone. The mixture of caustic alkalies and sawdust is made into a thick paste and then heated for several hours to a temperature which is gradually brought to 240° C. The gray mass is then washed with sodium carbonate, whereby the potassium is removed as carbonate, the less soluble sodium oxalate remaining. This is converted into calcium oxalate by milk of lime, and the calcium salt then decomposed with sulphuric acid and the resulting crude oxalic acid purified by recrystallization.

Oxalic acid occurs in colorless crystals, efflorescent in dry air, possessing considerable volatility, and a strong, sour taste. It is soluble in 4.5 parts of dehydrated alcohol, in 2.5 parts of alcohol, and almost insoluble in ether, chloroform, benzene, and petroleum benzin. The crystals should dissolve in ten parts of water at 25° C.; soluble in 3 parts of boiling water.

It fuses in its water of crystallization at 98° C., although continued exposure to a heat of from 60° C. to 70° C. will render it perfectly anhydrous. Solutions of oxalic acid at 100° C. lose acid by sublimation, and at 157° C. the anhydrous acid itself sublimes rapidly. If the heat rise to 160° C., partial decomposition, with consequent loss of acid, occurs. (See also *Oxalic Acid* under Reagents, Part III.)

It is a dibasic acid and combines with salifiable bases, forming oxalates. The most important of these are the three *potassium oxalates*, severally called *oxalate*, $K_2C_2O_4 + H_2O$, *binoxalate*, $KHC_2O_4 + H_2O$, and *quadroxalate*, $KHC_2O_4.H_2C_2O_4 + 2H_2O$, and *calcium oxalate*. Potassium binoxalate and quadroxalate, both popularly called *salt of sorrel* (*sal acetosella*), are also sometimes called by the dangerous misnomer *essential salt of lemons* (or *sal limonis*), are employed for removing iron mold from linen, and act by their excess of acid, which forms a soluble salt with the ferric oxide constituting the stain. Salt of sorrel is also used extensively in the bleaching of straw goods and other vegetable fibers. Oxalic acid is used for removing ink stains and iron mold, for cleaning the leather of boot tops, and for discharging colors in calico printing. Prussian blue dissolves in aqueous oxalic acid to clear blue liquid which is often employed as a *blue ink.*

Oxalic acid is a powerful and rapidly acting poison. From the general resemblance of its crystals to epsom salts fatal mistakes have occurred. It may, however, at once be distinguished by its sour taste. It acts on the economy in two principal ways, according as its solution is concentrated or dilute. When concentrated it causes great pain, followed by violent retching with bloody vomit, then sudden dulness, languor, and great debility, and finally death without a struggle. When dissolved in 20 times its weight of water oxalic acid possesses no corrosive and scarcely any irritating properties but is still capable of causing death by its depressant action upon the central nervous system and the heart. In such cases the symptoms have been great muscular weakness with twitchings of the muscles and more rarely convulsions; the respirations become slow, pulse weak and there maybe either pallor or cyanosis of the face. In fatal cases coma precedes the termination.

After death from oxalic acid the mucous membranes of the alimentary canal are either soft and pultaceous or entirely destroyed. The stomach usually contains a dark fluid, resembling coffee grounds, consisting chiefly of altered blood. In a few cases no morbid appearances have been discovered.

In 1879 Kobert and Kürsner announced that in animals oxalic acid may produce glycosuria; this has since been confirmed, and Sarganeck has noted the symptom in human poisoning, so that it is probably a constant phenomenon.

In the treatment of poisoning by oxalic acid, the remedial measures must be employed with great promptitude. Vomiting may be encouraged and the stomach tube used, but unless the antidote be at hand death will rarely be averted. The proper antidote is chalk or magnesia, mixed with water, and as soon as either can be procured, it must be administered in large and repeated doses. In many cases whitewash or some other preparation of lime can be obtained sooner than chalk, and should be at once administered; tooth powder can usually be obtained quickly, and generally (not always) consists chiefly of calcium carbonate. These substances act by forming with the poison an insoluble, inert calcium or magnesium oxalate. The soluble salts of oxalic acid, as ammonium oxalate and potassium oxalate, are equally poisonous, and the antidotes for them are lime water or solutions of magnesium salts.

Oxalic acid has been strongly recommended by Poulet and by Marsh (*T. G.*, 1891) in *amenorrhea.* Marsh has also found it serviceable in *cystitis.* It is a very active germicide, and its solution is used in conjunction with potassium permanganate for the disinfection of the surgeon's hands. *Dose,* half a grain (0.032 Gm.) from three to five times a day.

Oxalis. *O. Acetosella* L. (Fam. *Oxalidaceæ.*) *Wood Sorrel. Acetosella. Allêluia, Surelle, Pain de Coucou,* Fr. *Sauerklee, Hasenklee,* G.—Wood sorrel is a small, creeping plant having radical leaves and scapes from 5 to 15 cm. high. It is a native of Europe and naturalized in the Northern United States. Other indigenous species of *oxalis* possess similar properties to *O. Acetosella.* The whole herbaceous portion may be used.

Wood sorrel is without odor, and has an agreeable sour taste. It owes its acidity to *acid potassium oxalate* or *potassium binoxalate* (HKC_2O_4).

The fresh plant, eaten raw, is useful in *scurvy.*

Oxalis crassicaulis Zucc., a Peruvian species, yields edible tubers and, by expression from its leaves, a very sour and astringent juice, which is employed, in the form of syrup, in *hemorrhages, chronic catarrh,* and *gonorrhea,* with asserted advantage.

Oxycamphor.  $C_8H_{14}\left\langle\begin{array}{l}CHOH\\ \;|\\ CO\end{array}\right.$. This oxidation product of camphor is a white crystalline powder, melting at from 203° to 205° C. and volatile in a current of steam. Soluble to a slight degree in cold water; more soluble in hot water. It is decomposed by prolonged exposure to the air.

It is stated that oxycamphor acts as a stimulant to the cardiac muscle and also to the centric and peripheral vasomotor nervous system, and as a calmative to the respiratory centers. It has been used with asserted good results for the relief of both cardiac and pulmonic *dyspnea. Dose,* from eight to fifteen grains (0.5–1.0 Gm.). A fifty per cent. solution of *oxycamphor* in alcohol is sold under the trade name of *oxaphor.*

Oxychinaseptol. *Diaphtherin.* $C_6H_4(SO_2)\text{-}\begin{cases}O—NH.C_9H_6(OH)\\ O—NH.C_9H_6(OH)\end{cases}$. This substance is made by uniting two molecules of oxyquinoline, $C_9H_6N\text{-}(OH)$, with one molecule of phenol-sulphonic acid, $C_6H_5(HSO_3)OH$. It occurs in yellowish hexagonal crystals, melting at 85° C., very soluble in water and diluted alcohol. Its solution is decomposed by alkalies. According to the researches of Emmerich (*M. M. W.*, 1892), it is much more powerful as an antiseptic than phenol; two-tenths of one per cent. solution is sufficient to kill the comma or diphtheria bacilli in ten minutes, and three-tenths of one per cent. solution destroys the pus organisms in thirty minutes. It is also asserted that it is practically innocuous to higher animals, the subcutaneous injection of five cubic centimeters of a 5 per cent. solution producing no serious effects upon guinea-pigs. It has been used in practical surgery, especially by Kronacher, who has employed from ½ to 1 per cent. solution with great satisfaction for the general purposes of the antiseptic treatment of wounds. Such solution produces no irritation except in some cases a momentary burning. Rohrer (*Corresp. f. Schweiz. Aerz.*, Nov., 1892) commends the remedy as a local application in disease of the nasal mucous membrane. The solution does not stain the hands, but forms on steel instruments a black deposit which is readily washed off.

Oxydendrum. *Oxydendrum arboreum* (L.), DC. *Sour Wood. Elk Tree. Sorrel Tree.* (Fam. *Ericaceæ.*)—The leaves of this indigenous tree possess an acrid taste, whence the common names of the tree, and are said by eclectic physicians to be a powerful diuretic, useful in *dropsy.* A semi-solid extract may be made, one part representing five of the drug; *dose,* from five to fifteen grains (0.32–1.0 Gm.). Of the fluidextract the *dose* is from a half to two fluidrachms (1.8–7.5 cc.).

Oxysparteine. $C_{15}H_{24}N_2O$.—This is an alkaloidal oxidation product of sparteine, originally described by F. Ahrens (*B. Chem. G.*, 1891, xxiv).

It occurs in white, somewhat hygroscopic needles, melting at about 84° C., soluble in water, alcohol, ether, and chloroform. It has been found by Hurthle (*A. E. P. P.*, 1892) to be a cardiac stimulant, decreasing the pulse rate, but markedly increasing the arterial pressure and heart work. The hydrochloride, which occurs in large needles (often consolidated together) and is very soluble in water, has been used hypodermically by von Oefele in cases of *heart failure.* The *dose* is half a grain (0.032 Gm.), rapidly increased to one and a half grains (0.096 Gm.). The system is said soon to become accustomed to it.

Ozokerite.—This substance, which is found in Galicia, in Austria, and from near the Caspian Sea, as well as in Southern Utah, is in its crude state, a solid, varying in color from a dirty green to nearly black. When purified by treatment with sulphuric acid and alkali and subsequent filtration, while melted, through bone black or other filtering medium, it is a hard, white, spermaceti-like substance, and is extensively used in England as well as in Austria in the manufacture of candles. (See *Ceresin.*) It is a mixture of natural paraffins. It is said to resemble tar in its therapeutic properties, and, mixed with glycerin or linseed oil, has been employed in *skin diseases* as a substitute for that remedy. (See *Am. Drug.*, 1892, 40.)

Ozone (O_3) is recognized as an active modification of the element oxygen. It is considered to differ from the common form in being more condensed and at the same time more active. It has a peculiar odor, somewhat resembling that of diluted chlorine. *Ozone* changes gradually at the ordinary temperature into common oxygen, and at 237° C. the change is instantaneous. It is one of the most powerful oxidizing agents known, attacking and at once destroying organic substances, such as caoutchouc, paper, cork, etc. It also decolorizes most organic pigments. It is slightly soluble in water, imparting to water its peculiar odor, as well as its oxidizing power. According to Carius, 1000 volumes of water dissolve 4.5 volumes of ozone, and it is much more soluble in certain ethereal oils. The power of these latter as carriers of oxygen and deodorants is thus explained. At one time ozone was thought to be peroxide of hydrogen, but Marignac and De la Rive demonstrated its true nature. Hautefeuille and Chappius (*C. R. A. S.*, xciv, 1249) succeeded in producing "liquid ozone" by applying a pressure of 125 atmospheres to richly ozonized oxygen at −100° C. It is stated to be of a dark indigo color.

Ozone has not been obtained free from oxygen; indeed, it is probable that 1 per cent. of ozone is the highest concentration reached in its production. It is prepared by the decomposition of water by the battery, by the passage of the silent electric discharge through air or oxygen, by the slow oxidation of phosphorus in moist air and in other cases of slow combustion, and, lastly by the action of sulphuric acid upon barium dioxide and potassium permanganate.

The presence of ozone in the air or in gases is indicated by its action on paper moistened with potassium iodide and starch solution. This is turned blue, and if reddened litmus paper is moistened with potassium iodide, this is also blued. Another test is found in the use of paper moistened with an alcoholic solution of guaiacum, which is changed to light blue. Ozone may be readily determined in extreme dilution by the decolorizing effect which it has on fluorescein solution.

Its presence in the air is now fully established, although in thickly inhabited districts it is almost always absent, as it is reduced to ordinary oxygen by the organic emanations constantly sent out into the air. In the air of the country, and especially in sea air, the presence of ozone can often be recognized by its peculiar odor. The probable cause of the formation of ozone in the air has been pointed out by Gorup-Besanez, as he has shown that ozone is invariably formed when water evaporates, and it is to this source, rather than to the electrical discharges, that the production of ozone must be traced. Ozonizing machines, in which the gas is generated by the passage of an electrical spark, are used in some industrial establishments and cold storage plants for the purpose of deodorizing and purifying the air.

Contrary to the common superstition ozone has no disinfectant virtues. There is no evidence that it has any more therapeutic use than ordinary oxygen.

Pæonia. *Pæonia officinalis* L. *Peony. Pentecost Rose. Pivoine*, Fr. *Gichtrose, Pfingstrose*, G. (Fam. *Ranunculaceæ.*)—The subterranean portion of this garden peony consists of a thick rhizome which sends off in all directions spindle-shaped roots, which gradually taper into thread-like fibers, by which they hang together. It has a strong, peculiar, disagreeable odor, and a nauseous taste, which is at first sweetish, and afterwards bitter and somewhat acrid. The odor is lost, or much diminished, by drying. Peony "root" was in very great repute among the ancients as a charm and as a medicine in *epilepsy.* In modern times it has been used as an antispasmodic. Its expressed juice is milky and of a disagreeable odor and taste. According to Rochebrune (*Toxicolog. Africaine*, i), it contains an active alkaloid, *pæonine* which has been used as a styptic. The *seeds* are roundish-oval, about as large as a pea, externally smooth, shining, and nearly black, internally whitish, inodorous when dry, and of a mild oleaginous taste. By some authors they are said to be emetic and purgative, by others antispasmodic. The *dose* of the fresh root or seeds is from two drachms to an ounce (7.7–31.0 Gm.), boiled in a pint of water down to half a pint, which should be taken daily. It is said to be less active when dried.

W. Will obtained from an aqueous distillate of the root of the Japanese *Pæonia Moutan* Simson, an aromatic ketone in colorless crystals. (*B. Chem. G.*, xix, 1777.) According to Nagae, this substance has the formula $C_9H_{10}O_3$. (*Ibid.*, xxiv.) It has been prepared by Schimmel & Co., under the name of *peonol.* It has a pleasant aromatic odor, and crystallizes in large needles. No essential oil was found in the root. (*Schim. Rep.*, Oct., 1890.) Dragendorff has found in the seed of *P. peregrina* Mill., a fixed oil, an alkaloid, and *pæonic acid.* (*Jahresb.*, 1879.)

Palicourea. *Palicourea rigida* H. B. K. (Fam. *Rubiaceæ.*)—The leaves of this tree are used in Brazil as a diuretic and diaphoretic. In 1866 Peckholdt found in them an alkaloid and three organic acids. One of these acids consisting of a yellow, oily liquid with an overpowering odor, was found to be distinctly poisonous, one drop injected into a pigeon being enough to cause death. This was called *myotonic acid.* A crystalline *palicouric acid*, an amorphous tannin, and another amorphous non-toxic bitter principle were also isolated. Santesson has confirmed the presence of an alkaloid. (*A. Pharm.*, 1897, ccxxxv.)

Palladious Chloride. *Palladous Chloride. Palladii Chloridum.* $PdCl_2$.—This is a blackish-brown mass, soluble in water, which has been recommended as a reagent for determining the malic acid in wine. It has been used to some extent in medicine as a local germicide, and has been recommended in the treatment of *phthisis* in *doses* of one-fourth to one-third of a grain (0.016–0.021 Gm.) three or four times a day.

Under the name of *leptynol* an emulsion of *palladium hydroxide*, $PdOH_2$, has been employed as an injection for the treatment of *obesity* by Kauffmann. (*M. M. W.*, 1913, p. 1260.) Two cc. of this preparation, containing 50 mgm., are injected once a week into the abdominal fat.

Panase. *N. N. R.* 1924.—This is a combination of the digestive enzymes of the pancreas, derived from the pancreatic glands of the pig. It is a light, yellowish-white powder, having a slight animal odor and a somewhat mucilaginous taste. It is not entirely soluble in water or in glycerin, due to a small amount of proteid present. This can, however, be filtered out without impairing the digestive quality of the solution. *Panase* is incompatible with strong alcohol, acids, alkalies and other substances which destroy the activity of ferments. It is used for the same purposes as pancreatin. *Dose*, two grains (0.13 Gm.).

Panbotano Bark.—The root of the Mexican leguminous tree, *Calliandra Houstoni* Benth., has been highly recommended by Valude as an antiperiodic, although Villejean was not able to find in it either an alkaloid or a glucoside. (*Journ. de Sci. Méd. de Lille*, 1890.) Pouchet (*Nouv. Rem.*, 1896), however, states that he has found in panbotano, besides a saponin, an alkaloid which produces death by systolic arrest of the heart. Both Dinau (*Thèse de Paris*, 1896) and Crespin confirm its antiperiodic value. (*B. G. T.*, Aug., 1895.) A tincture representing two ounces of the root is taken in four *doses* during twenty-four hours.

Pancreon (*pankreon*) is a preparation obtained by the action of tannic acid on pancreatin containing 8 per cent. of the former in combination. It is a grayish, odorless powder soluble in water and acidulated liquids and is affirmed to have strongly trypsilytic, amylolytic, and emulsifying properties. It is further claimed to be superior to pancreatin in not losing its activity in the stomach. *Dose*, eight to fifteen grains (0.5–1.0 Gm.).

Pangium. *Pangium edule* Reinw. (Fam. *Bixaceæ.*)—This East Indian tree, which is said to possess anthelmintic and narcotic properties, and to be capable of causing death, according to Blume, contains an alkaloid resembling *menispermine.*

Pantopon. *N. N. R.* 1924. **Omnopon.**—Sahli introduced, in 1908, this combination of the alkaloids of opium as being more actively narcotic in proportion to its poisonous properties than morphine and having the advantage over crude opium that it was fitted for hypodermic administration. Both Straub (*Biochem. Zeit.*, 1912, xli, p. 419) and Macht (*J. P. Ex. T.*, 1915, vii, p. 339) have shown that narcotine is stimulating to the respiratory center and therefore antagonistic to morphine and codeine. There are, therefore, scientific grounds for this combination and the conclusions of Sahli have received considerable clinical confirmation. The *dose* of *pantopon* should be about double that of morphine. From one-sixth to one-third of a grain (0.010–0.021 Gm.) may be given by mouth.

A similar combination of opium alkaloids is sold under the name of *toponal* (*D. C.*, 1915, p. 580).

Pao-Pereira Bark. *Pereiro Bark.*—Under this name a bark is employed in Brazil as a febrifuge. It is supposed to be the product of *Geissospermum læve* (Vell.) Baill. (Fam. *Apocynaceæ*). O. Hesse (*B. Chem. G.*, 1893, xxvi, 1045) has found an alkaloid, *geissospermine*, $C_{19}H_{24}O_2N_2 + H_2O$, in it, but he seems to have been preceded in this discovery by Santos (*A. J. P.*, 1878, 184.) Peretti has discovered in the root a second alkaloid, *pereirine*, $C_{19}H_{24}N_2O$, which, according to Guimaraes (*B. M. J.*, vol. i, 1887), in sufficient doses causes paralysis with elevation of temperature, ending in death. It has been given to man as an antiperiodic in *doses* of thirty grains (2.0 Gm.) a day. (See also *A. J. P.*, 1886, 278.) Later a third alkaloid, *vellosine*, $C_{23}H_{28}O_4N_2$, was found by Freund and Favet (*Ann. Ch. Ph.*, 1894, cclxxxii, 247). This forms colorless crystals, melting at 189° C., insoluble in water, easily soluble in alcohol and ether. In concentrated nitric acid it dissolves with a purplish-red color, which is very stable.

Papaya. *Melon Tree. Papaw.*—The *Carica Papaya* L. (Fam. *Caricaceæ*) is an unbranched tree growing to the height of 20 feet, with large palmately 7-lobed leaves and fruits which frequently attain the size of a human head. It is commonly cultivated in tropical countries for the sake of its fruit. The ovoid fruit sometimes attains a length of 30 cm. and weight 4 or 5 kilogramme. This tree should not be confused with the indigenous *Asimina Triloba* which is, unfortunately, commonly known as the American papaw; there is neither botanical nor medicinal relationship between these trees (see *Asimina*). According to Peckholdt (*P. J.*, Nov., 1879), the milky juice is contained in all parts of the tree, but in such small quantity, save in the unripe fruit, that it is always procured from the latter. One fruit will yield about 33 Gm., which is obtained by scratching through the skin in various places; the process does not interfere with the ripening of the fruit, but it is said that the seeds will not germinate. The milk-juice is collected in porcelain-lined receptacles and allowed to evaporate to a granular condition whence it is marketed as crude papaïn. The juice has an acid reaction, an astringent bitterish taste, and a sp. gr. of 1.023. Upon standing for a few minutes it separates into two parts, an aqueous liquid and a white, somewhat coagulated pulpy mass. In the aqueous portion is an albuminous substance, possessed of enzymic properties, to which the names of *papaïn* and *papayotin* have been given. According to the researches of S. H. C. Martin, papaw juice contains besides papaïn, a milk-curdling ferment, globulin, albumin, and two phytalbumoses. No peptones occur in the juice, but leucine and tyrosine are present. (*J. Chem. S.*, 1886, 642; see also *P. J.*, 1885, 129.) In a representative preparation the ferment action seems to be most marked when all the proteids are associated together in the natural form. In its action upon albumin the enzyme of the papaw produces substances which have a close relation to those produced by tryptic and peptic digestion. In the action of the papaw ferments on milk there is first curdling in which the casein is separated into a soft flocculent precipitate, and afterwards a digestion of the proteids, during which process they are converted into soluble and diffusible products. The amount of starch-converting ferment is not large, but sufficient in the fresh latex to promptly act upon starch paste, thinning it, and converting a portion at least into soluble starch and dextrin. The report of the presence of rennet ferment and pectase requires further investigation.

According to Wurtz, fibrin is dissolved whether the solvent solution be alkaline or acid. Brunton and Wyatt and also Martin affirm, however, that one-half per cent. of hydrochloric acid will prevent digestion, but Albrecht reasserts that hydrochloric acid hastens the action of the ferment, and states that the official preparation in use in Paris hospitals is an acid one. In order entirely to convert fibrin into pure peptone so that nitric acid will produce no precipitate, the proportion of the ferment should be as great as 3 per cent., and digestion must continue for forty-eight hours at 50° C.

The seeds of the papaw tree contain a glucoside, *caricin*, which resembles sinigrin. These seeds also contain the ferment, myrosin, and by the reaction of the two a volatile pungent body is produced, suggestive of oil of mustard in odor. An alkaloid, *carpaine*, $C_{14}H_{25}O_2N$, has been obtained from the leaves by Greshoff; it has been more closely studied by Barger (*B. P. G.*, 1914, xxiv). Physiologically, this alkaloid is said to affect the heart like digitalis. (*A. J. P.*, 1901, 336 and 383.)

Under the name of *papayotin*, *papaïn*, or *papoid*, the dried juice of the *Carica Papaya* is put upon the market. As it occurs in commerce, papaïn is a grayish, fine powder, which in appearance, odor, and taste strongly suggests pepsin. It is frequently adulterated with starch, which is not naturally present in the fruit. Its digestive power is far below the claims formerly made for it. It is asserted for it that, when the stomach is acid, it is much superior to pancreatin, because its action is not markedly affected by contact with the acid. In experiments made by H. C. Wood with a papoid from one of the most renowned manufacturers no digestion occurred, and it is probable that much of the article of commerce is inert. It has been used as an internal medicine in *dyspepsia* and *gastric catarrh*, and as a local application for the destruction of false membranes, *warts*, *tubercles*, walls of old sinuses, and even of *epithelioma*. (See Branch, *B. M. J.*, 1907.) Jacobi affirms (*T. G.*, vol. ii) that diphtheritic membranes are dissolved in a few hours by the hourly application of a mixture of one part of papaïn with two parts each of water and of glycerin. It is stated that from time immemorial the fresh leaves of the papaya plant have been used by the Indians to wrap meat in to make it tender, and as a dressing to *foul wounds*. According to Brunton, the *dose* is from five to ten grains (0.32–0.65 Gm.). Injected into the venous circulation it acts as a powerful poison, of which a single grain is sufficient to kill a rabbit.

Paradimethylaminobenzaldehyde (Dimethyl-p-amino-benzaldehyde), $(CH_3)_2N.C_6H_4.CHO$.—"Colorless scales fusing at 73° C.; soluble in hot water. The addition of an alcoholic solution of benzidine (1 in 100) to a slightly acidified solution of paradimethylaminobenzaldehyde produces a brick-red precipitate after standing." *U. S. IX.*

It is used in testing urine for bile pigments (see *Diagnostic Reagents.*)

Paralaudin.—This is stated to be a *diacetyldihydromorphine* and is used as a substitute for diacetyl-morphine and in the same dose.

Parameria. *Parameria vulneraria* Radlkofer. (Fam. *Apocynaceæ.*)—This tree yields the *Balsamo de Taguloway* of the Malays. (See *A. Pharm.*, Nov., 1885.)

Paramidoacetophenone. $C_6H_4.NH_2.CO.CH_3$.—This substance occurs in crystals soluble in boiling water, alcohol, and ether, and melting at 106° C. It has been used in the practical application of Ehrlich's *diazo test.* (See *Diagnostic Tests.*)

Paramorfan. *Dihydromorphine hydrochloride*, $C_{17}H_{21}O_2N.HCl$.—It is a white, crystalline powder, soluble in water and slightly in alcohol. It is used for the same purposes as morphine. It is given in *doses* of from one-sixth to one-third of a grain (0.01–0.02 Gm.).

Parsley. *Ache, Persil*, Fr.; *Petersilie*, G.; *Prezzemolo*, It. *Petroselinum sativum* Hoffman (*Apium petroselinum* L.).—The *common parsley*, which is used extensively as a culinary herb, is a hardy biennial bearing pinnately-compound leaves which in the cultivated varieties are greatly divided. During its early stages the leaves are arranged in rosettes and the plant is six inches or less above the ground; the flowering and fruiting plant, however, is from 2 to 3 feet in height. It is a native of Sardinia and was introduced into England in 1548, and is naturalized in salt marshes on the coast of California. It has been cultivated as a sweet herb since earliest times and was used by the ancient Greeks and Romans as a part of their festive garlands on account of retaining its color so long.

Both the root and the fruit of parsley have been used in medicine. The fruit, often incorrectly called *parsley seeds*, consists of two dried mericarps which in the fresh state are joined along the center commissure. The U. S. P. IX described them as follows: "Mericarps usually separated, ovoid-crescent shaped, from 2 to 3 mm. in length and about 1 mm. in diameter; externally grayish-brown, becoming grayish or brownish on aging, having 5 yellowish, filiform, prominent ribs, alternating with the coarsely roughened furrows; in transverse section nearly hemispherical, the commissural surface with 2 vittæ or oil-tubes, the dorsal surface usually with a single vitta, occasionally 2 vittæ in the groves between the primary ribs; endosperm large, oily, enclosing a small embryo; odor and taste characteristic and aromatic, especially when bruised. Under the microscope, sections of Parsley Fruit show an epidermal layer with thick cuticularized walls having numerous small centrifugal projections; several layers small thin-walled parenchyma cells, being usually considerably collapsed and occasionally containing a rosette aggregate of calcium oxalate; a single, large, brown, elliptical vitta or oil-tube between each of the primary ribs and surrounded by a layer of comparatively large yellowish-brown, tangentially elongated cells; a singe fibrovascular bundle more or less surrounded by a few or occasionally numerous sclerenchymatous fibers; inner epidermis of narrow, thin-walled elongated cells closely cohering with the brownish tabular cells of the seed-coat; commissural surface usually with 2 large vittæ, a very few stone cells and showing a slight separation of pericarp and seed-coat; endosperm of polygonal, thick-walled parenchyma cells containing fixed oil and numerous, small aleurone grains, usually containing a small rosette aggregate of calcium oxalate. The vittæ usually contain yellowish oil globules or a resin-like mass adhering to the walls, and occasionally are divided by a radial wall. The powder is grayish-brown; mostly of large, irregular fragments; cells of endosperm with aleurone grains, each usually containing a rosette aggregate of calcium oxalate, from 0.003 to 0.007 mm. in diameter; fragments with light yellow vittæ and the yellowish-brown cells of the pericarp; fragments with narrow tracheæ and more or less lignified sclerenchymatous fibers." *U. S. IX.*

Parsley root (*Petroselini Radix, N. F. IV*) was described as "The entire fusiform root, measuring up to 20 cm. in length and up to 2.5 cm. in thickness at the crown, or broken or cut into pieces; usually cut lengthwise into two or four sections; externally light yellowish, wrinkled longitudinally, somewhat annulate, root scars distinct and corky; fracture tough when damp, brittle when dry; internally, cortex whitish and characterized by numerous, reddish-brown oleoresin cells, cambium zone distinct and brownish; wood about the same thickness as the cortex, slightly radiate and light yellow. Odor aromatic; taste sweetish and pungent. The powdered drug, when examined under the microscope, shows numerous truncate or somewhat angular starch grains up to 0.03 mm. in diameter, reticulate tracheæ up to 0.06 mm. in width and thin-walled, lignified fibers with simple pores. Parsley Root yields not more than 6 per cent. of ash." *N. F. IV.*

All parts of the plant contain a volatile oil, to which it owes its odor and mainly its taste, as well as its use in seasoning. This oil consists of a hydrocarbon, $C_{10}H_{16}$, probably pinene, and apiol. Braconnot (*B. Chem. G.*, 1876, 1121) obtained from the herb a peculiar substance, resembling pectic acid in appearance, which he named *apiin*. This has been stated to be a glucoside but Joret and Homolle believe it is identical with pectin. It is soluble in hot water and on cooling forms a gelatinous mass. When purified it forms silky needles of the formula $C_{27}H_{32}O_{16}$. *Apiol*, or *parsley camphor* occurs as a white crystalline solid with a faint odor of parsley, insoluble in water but soluble in alcohol, ether and fixed oils. It is the di-methoxymethylene ether of allyl-tetraoxybenzene, $C_{12}H_{14}O_4$.

Ciamician and Silber (*Ph. Post*, 1888, 391) have investigated apiol, and state that the pure substance occurs in white crystals having the composition $C_{12}H_{14}O_4$, melting at 30° C., and boiling at 294° C. *Isapiol, apiolic acid, apiolaldehyde,* and *apion* are decomposition products. They state that isapiol has physiological properties resembling those of pure apiol.

The term "apiol" or "liquid apiol" is often applied to the *oleoresin* (*Oleoresina petroselini* U. S. IX) also often known as *oil of parsley seed.* The method of preparation of this was as follows:

"Parsley Fruit, in No. 60 powder, *five hundred grammes;* Ether, *a sufficient quantity.* Place the parsley fruit in a cylindrical glass percolator provided with a stop-cock and arranged with a cover and a receptacle suitable for volatile liquids. Pack the powder firmly and percolate slowly with ether, added in successive portions until the drug is exhausted. Recover the greater portion of the ether by distillation on a water bath, and, having transferred the residue to a dish, remove the remaining ether by spontaneous evaporation in a warm place, stirring frequently. Allow the Oleoresin to stand without agitation for four or five days, decant the clear liquid portion from any solid residue, and preserve it in well-stoppered bottles." *U. S. IX.*

Parsley root was used chiefly as a diuretic in dropsies and various inflammatory conditions of the urinary organs. Cow (*A. E. P. P.*, 1912, lxx, p. 393) has shown, however, that it has very feeble physiological action.

The oleoresin of parsley contains a number of bodies of considerable physiological power. The most important of these are crystalline apiol, white apiolin, and myristicin. According to the experiments of Lutz (*Bull. Sci. Pharm.*, 1910, xvii, p. 1) the actions of these substances are similar in kind. They produce marked slowing of the pulse with fall of the blood pressure, tremors, and weakness of the extremities, followed by paralysis with epileptiform convulsions and gasping respirations. After death there was found marked congestion in the lungs and in the pelvic organs. Rimini and Dilitala (*Archiv. di. Farmacologia e. Terap.*, 1908, xiv) have shown that apiol produces in the cat fatty degeneration of the liver of the same type as is caused by myristicin (see under *Oleum Myristicæ*). They also noted that it had a direct weakening action on the voluntary muscles.

Apiol has been attributed with the possession of antiperiodic properties, but is chiefly employed in *dysmenorrhea* and other uterine disorders. There is, however, no satisfactory evidence that we know of, either experimental or clinical, that it possesses any real therapeutic value.

Glatard (*Journ. de Med. et Chir. Prat.*, 1910, p. 674) report a case of apiol poisoning in a pregnant woman who took six grammes in a period of forty-eight hours. There was vertigo, nausea and vomiting, urticaria, liver swollen and painful, mild icterus, urine scanty and high colored, but free from albumen; pregnancy was not interrupted. Sardou (*A. G. M.*, 1906) recommends apiolin as an antispasmodic in *intestinal colic.*

The *dose* of parsley-root is about 30 grains (2 Gm.); a fluidextract was formerly official. The oleoresin may be given in doses of five to fifteen minims (0.3–1 cc.).

Parietaria. *Parietaria officinalis* L. *Wall Pellitory. Pariétaire, Perce-muraille,* Fr. *Glaskraut,* G. (Fam. *Urticaceæ.*)—A perennial European herb, growing on old walls and heaps of rubbish. It is diuretic and refrigerant, and was formerly used in urinary complaints and *dropsy*, in the form of decoction or of the expressed juice.

Paris Green. *Schweinfurt Green. Aceto-Arsenite of Copper.* $Cu(C_2H_3O_2)_2.3Cu(AsO_2)_2$.—This substance, which was originally made for a pigment, is now used to an enormous extent for dusting on potato vines to destroy the so-called *potato bug*, or *Colorado beetle, Doryphora decemlineata.* It is made by mixing five parts of verdigris with sufficient water to form a thin paste, and adding to this a boiling solution of four parts of arsenic trioxide in fifty parts of water, keeping the mixture at the boiling temperature, and adding a little acetic acid to cause it to retain a brilliant color. Numerous cases of poisoning have occurred through carelessness in its use as an insecticide. The treatment would be the same as that for poisoning by arsenic.

Parkia. *Parkia biglandulosa* W. and A. (*P. africana* R. Br.) *African Locust. Nitta* or *Nutta Tree. Doura. Houllé. Neretou.*—This is an African leguminous tree, from the dried seeds of which a farinaceous food is prepared by the natives. According to DeRochebrune (*Toxicolog. Africaine,* 1898), it contains a peculiar crystalline alkaloid, *parkine*, which resembles, in its physiological activity, physostigmine.

Parthenium. *Chrysanthemum Parthenium* (L.) Bernh. *Feverfew. Matricaire*, Fr. *Mutterkraut*, G. (Fam. *Compositæ.*)—A tall, strongly scented, perennial, branching herb, with bipinnately divided leaves, the segments being oblong or elliptic-oblong and cut, and small flower-heads arranged in a corymb. It is a native of Europe, but cultivated in our gardens and naturalized in some places. The whole aerial part is used. The plant has an odor and taste analogous to those of chamomile, which it resembles also in the appearance of its flowers and in its medicinal virtues. It yields a greenish volatile oil which boils between 165° and 220° C., and separates on standing, *pyrethrum camphor*, $C_{10}H_{16}O$.

The flower-heads of this and of a closely resembling species, *Matricaria parthenoides* Desf., (*Chrysanthemum parthenoides* Voss), are said to be used in France, to a considerable extent, indiscriminately with those of the true chamomile plant, *Anthemis nobilis*, which they closely resemble, especially when double. They may, however, be distinguished, in this state, by their peculiar odor, their small receptacle, which is, moreover, rounded and flattened above, instead of being conical and somewhat pointed as in the *Anthemis*, and by the tubular five-toothed central florets, which in the chamomile are small, few, and scarcely visible, but in the two former species are large, very numerous, and very long.

Parthenium Hysterophorus L.—José Torar has found *parthenine* and four other alkaloids besides *parthenic* acid, in this cuban plant which is used by the natives as a febrifuge and antiperiodic. Of the alkaloids, *parthenine* is crystallizable and is apparently the active principle. It has been extracted and studied again by H. V. Arny (*A. J. P.*, 1890, 121), who believes it to be a bitter glucoside and not an alkaloid. In doses of three grains (0.2 Gm.) it is said to quicken the heart, and in doses of fifteen grains (1.0 Gm.) to slow cardiac action, while fifty grains (3.2 Gm.) not only lessen the arterial pressure and respiratory frequency but reduce the bodily temperature. In *doses* of from seven to ten grains (0.45–0.65 Gm.) it is affirmed to be useful in *neuralgia.* (See *Journ. de Méd. de Paris*, March, 1887; *A. J. P.*, 1897, 169.)

Parthenium integrifolium L., *American Feverfew. Prairie Dock. Wild Quinine* (Fam. *Compositæ*) is an herbaceous perennial, growing abundantly in the prairies of the Southwestern States, which has been used as a tonic and antiperiodic; two ounces (62 Gm.) of the flowering tops may be given in infusion.

Paulowilhelmia. *Paulowilhelmia speciosa* Hochst.—This acanthaceous plant is used by the Aquapine tribe on the Gold Coast, as a fish poison, under the name of *adubiri.* (*P. J.*, xx, 1890.)

Peach Leaves. *Prunus Persica* (L.) Sieb. et Zucc. (Fam. *Rosaceæ.*) *Pechier*, Fr. *Pfirsich*, G. —The peach tree is a native of China, but flourishes everywhere in the warm temperate zone. Peaches are among the most grateful and wholesome of our summer fruits. They abound in saccharine matter, which renders their juices susceptible of the vinous fermentation, and a distilled liquor prepared from them has been much used, in some parts of the country, under the name of *peach brandy.* The kernels of the fruit resemble, physically and chemically, bitter almonds, for which they are frequently substituted in commerce. The flowers, leaves, and bark also have the peculiar odor and taste of bitter almonds, and yield hydrocyanic acid. The leaves afford a volatile oil by distillation. The distilled water prepared from them was found in one instance to contain 1.407 parts of hydrocyanic acid in 1000, and in another only 0.437 parts in the same quantity. From some experiments it is inferred that the proportion of acid is greatest where there is least fruit. (*A. J. P.*, xxiv, 72.)

Peach kernel oil made by expression has found its way into Western Europe from the Levant, and is used in Italy and Southern France largely as an adulterant of almond oil. It is described as of a light yellow color, having the taste and odor of almond oil. It thickens at –9° C. or –10° C., and solidifies at –18° C. The sp. gr. at 15° C. is 0.915. It gives with strong nitric acid a dark brown color, with sulphuric acid a dark brown becoming lighter, with solution of zinc chloride a purplish-brown; forming with the elaidin test in two hours a mass of butter-like color and consistence. Peach kernel oil has a saponification value of 189–192 and an iodine figure of 93.5. (See *Oleum Amygdalæ Expressum*, Part I.)

The leaves of the peach are said to be laxative, and have also been used with asserted advantage in *whooping cough, irritability of the bladder*, etc. The dried leaves may be employed (an ounce to a pint of hot water) in infusion. The flowers of the peach are affirmed to be laxative and vermicidal, in half-fluid-ounce (15 cc.) doses when fresh, given in the form of syrup. Cases of fatal poisoning in children from their use are on record. The peach kernels are distinctly active, and when rubbed up with cold water form an emulsion which may be used in place of cherry-laurel water or other preparations of hydrocyanic acid.

Peganum. *Peganum Harmala* L. *Wild Rue.* (Fam. *Rutaceæ.*)—A tall herbaceous plant growing in the Mediterranean region of Europe and Africa and extending into Thibet. In the seeds of this plant Goebel (1837) found the alkaloid *harmaline*, and Fritzsche (1847) a second alkaloid, *harmine.*

Harmine, $C_{13}H_{12}ON_2$, crystallizes in rhombic prisms which melt at 257°–259° C. (See Fischer, *B. Chem. G.*, 1912, xlv and 1914, xlvii, 99; also Perkin and Robinson, *Tr. Chem. Soc.*, 1919, cxv, 967.)

Harmaline or *harmine dihydride*, $C_{13}H_{14}ON_2$, is in the form of trimetric, octahedral crystals. It is soluble in alcohol and ether and slowly so in water. It melts at about 238° C. with decomposition. Flury (*A. E. P. P.*, 1911, lxiv, p. 105) finds that harmaline in moderate doses produced symptoms in the dog similar to those produced by cannabis and in toxic quantities it caused salivation. Its anthelmintic effect he attributes to a paralytic action upon the muscular tissues of the worm. The seeds of *peganum* were used by the ancient Greeks in the treatment of eye diseases. In modern times it has been used as an emmenagogue, anthelmintic and sedative.

Pegnin. *Milk-sugar Rennet.*—Under this name is marketed the milk curdling enzyme of calf's rennet diluted with milk-sugar and a little sodium chloride. It is a fine, white powder, having a sweet saline taste, readily soluble in water, forming a solution that rapidly coagulates the casein of milk. It is used mainly in the extemporaneous preparation of infant food and in stomachic disturbances, such as *hyperacidity* and *flatulence.*

Pelargonium. *Pelargonium odoratissimum* Willd. *Rose Geranium. Nutmeg Geranium.* (Fam. *Geraniaceæ.*)—The *Pelargoniums*, commonly referred to as *geraniums*, are indigenous to South Africa and largely cultivated as decorative plants. Some of the species are cultivated for the distillation of the volatile oil, in France, Spain, Algiers, and the Island of Réunion. According to Guibourt, several species of *Pelargonium* yield a volatile oil by distillation, closely analogous in odor to that of the rose: such are the species above named, *P. capitatum* Ait., and *P. roseum* Willd., which is probably a variety of *P. radula* Ait. The oil is obtained from the leaves. The oil which occurs in commerce, purporting to be the oil of *P. odoratissimum*, is fluid at ordinary temperatures, of a pale brownish-yellow color, and the characteristic odor of the plant, merely recalling that of the rose. This oil is now much used in perfumery. Piesse states that, as this oil is used to adulterate that of roses, so is it in its turn adulterated with the cheaper oils of species of *Andropogon*, especially the oil known as *oil of palmarosa* (see *Oil of Citronella*). Jallard states that the true oil of rose geranium, from *P. roseum*, is freely soluble in 70 per cent. alcohol. The oils likely to be used to adulterate it are insoluble in this liquid. If, therefore, six drops of the suspected oil be mixed with 5 cc. of 70 per cent. alcohol, there should be no separation. F. W. Semmler (*B. Chem. G.*, xxiii, 1098) has shown that the chief ingredient in the various geranium oils is an alcohol, *geraniol*, $C_{10}H_{18}O$, which boils at from 231° to 232° C., and has a sp. gr. 0.884 at 15° C. When oxidized by chromium trioxide mixtures, it is changed into *citral*, $C_{10}H_{16}O$, an aldehyde found in many of the essential oils, and this when oxidized by silver oxide yields *geranic acid*, $C_{10}H_{16}O_2$. The geraniol is both free and combined as tiglic acid ester. The oil also contains citronellol. (*Schim. Rep.*, April, 1897.) Geranium oil is sometimes adulterated with dimethyl sulphide, $(CH_3)_2S$. (*Schim. Rep.*, 1909, 55; see also *Am. Perf.*, Jan., 1913.)

Pengawar Djambi. *Paku Kidang. Golden Moss.*—This is composed of silky, long, yellow or brownish hairs, very soft, which are obtained in Java, Sumatra, from the base of the fronds of various ferns, especially *Cibotium Barometz* Link, *C. glaucum* Hook. et Arnold, *Alsophila lurida* Bl., etc. (Fam. *Cyatheaceæ*). (See also *S. W. P.*, 1910, No. 43, 361.) It has the power of causing rapid coagulation of blood, and, when properly used, of mechanically arresting hemorrhages from capillaries. It has been much used in the physiological laboratories of Europe and this country, and was employed in human medicine during the Middle Ages under the name of *Agnus Scythicus.* The medieval drug was composed of pieces of the rhizome with the attached scales and petioles so cut as to resemble animals. (See *L. M. R.*, Dec., 1887.)

Peralga. *Veramon.*—This is a compound of amidopyrine and barbital. It occurs as a yellow powder, sparingly soluble in cold water but readily soluble in hot water and various organic solvents. Its melting point is 95° to 97° C.

Peralga is intended for the relief of various pains such as *headache, dysmenorrhea, neuritis,* etc. It is asserted that it will even relieve traumatic *pains.* The *dose* is from five to nine grains (0.2 to 0.6 Gm.).

Penthaclethra. *Penthaclethra macrophylla* Benth. (Fam. *Leguminosæ.*) *Owalá Grains.*—The mussel-shaped seeds of this plant, which grows in the Congo States, are said to contain an alkaloid, *paucine*, crystallizing in yellow foliaceous crystals, melting at 126° C., insoluble in ether and chloroform, having the formula $C_{27}H_{38}O_5N_5$. (*P. J.*, lix); it is stated to be physiologically inactive. These seeds had formerly been employed as a Physostigma adulterant.

Peptones.—The general name of a class of albuminoids resulting from the hydrolysis of the nitrogenous elements of food (such as albumin, fibrin, casein, etc.), by the action of the digestive juices. This conversion is caused by the gastric ferment pepsin, and also by trypsin present in the pancreatic juice.

The physiologists of the preceding generation considered peptones to be the final product of digestion of proteins. It is now believed, however, that the peptones are further broken down into so-called *amino-acids.* The peptones cannot be regarded as final products of digestion and it has been definitely established that they cannot be utilized by the body tissues. Indeed, if introduced into the circulation, they have a distinctly toxic action.

Peptones are soluble in water, are not precipitated by potassium ferrocyanide in the presence of acetic acid, and are not coagulated by heat.

The commercial peptones, such as *Witte's peptone*, are the results of incomplete digestion, being mixtures of various *proteoses* and peptones. They vary considerably in their physical appearance and may occur either as powders or pastes. More usually they are in the form of a dark brown paste with a characteristic odor suggesting that of roast meat, soluble in water.

The peptones have the nutritious properties of the proteins from which they are derived. They are frequently employed in diseased conditions with the idea that being already partially digested they make less demand on the digestive organs. They have been also used for the purpose of exciting the protein reaction in the treatment of certain infections. (See *Protein Therapy*). They are also used for technical purposes especially in bacteriology. The U. S. P. IX recognized, among the reagents, *beef-peptone* describing it as: "The dried product of the pancreatic digestion of meat. A yellow powder of a slightly bitter but not disagreeable taste and an odor resembling that of meat extract. Soluble in all proportions in water, yielding a yellowish-brown liquid of faintly acid reaction. Slightly soluble in diluted alcohol, insoluble in alcohol or ether. An aqueous solution of peptone (1 in 20), upon the addition of tannic acid T.S. or mercuric chloride T.S., yields a precipitate. On the addition of 0.5 mil of potassium hydroxide T.S. to an aqueous solution of peptone (1 in 20), followed by a solution of copper sulphate (1 in 50), added drop by drop with agitation, an intense, red-violet color is produced (biuret reaction). Pour an aqueous solution of peptone (1 in 20) into an excess of alcohol, allow the resulting precipitate to settle and decant the clear supernatant liquid; the residue left on evaporating this liquid is completely soluble in alcohol and no coagulation occurs. One Gm. of peptone dissolves in 20 parts of water with but slight turbidity. When an aqueous solution of peptone (1 in 200) is heated to boiling, no precipitation occurs; the addition of nitric acid does not cause turbidity (*coagulable albumin*).

Saturate an aqueous solution of peptone (0.5 Gm. in 20 mils) with powdered zinc sulphate; not more than a slight flocculent precipitate appears (*proteoses*). Dry 1 Gm. of peptone at 100° C., it loses not more than 7 per cent. in weight; ignite this dried product; not more than 0.005 Gm. of ash remains. Peptone contains not less than 12.5 per cent. of nitrogen when determined by the Kjeldahl method, corresponding to about 78 per cent. of pure peptone." *U. S. IX.*

The term peptone has been greatly abused in commercial usage, being applied to a variety of preparations containing partially digested foodstuffs, both carbohydrate and protein, some also containing considerable amounts of alcohol. Vinous solutions containing from 5 to 10 per cent. of partially digested proteins are largely employed under various trade names as accessory foods. Their nutritive value is generally less than that of milk, and even this is due in large part to the alcohol they contain.

Perezia Root.—This root is obtained from several Mexican plants, *Perezia Wrightii* A. Gray, *P. Nana* A. Gray, and *P. Dugesii* A. Gray. (Fam. *Compositæ.*) It contains *pipitzahoic acid*, $C_{15}H_{20}O_3$, a substance which crystallizes in beautiful golden yellow needles. R. Anschütz and J. W. Leather obtained this acid also from the dried roots of *P. adnata* A. Gray. (*Trixis Pipitzahoac* Schaffner). It melts at from 103° to 104° C., sublimes readily, and is easily soluble in alcohol, ether, chloroform, benzene, and glacial acetic acid. It is a quinone, and bears great resemblance, when recrystallized from diluted alcohol, to *oxythymoquinone*, which, recrystallized from the same liquid, is scarcely distinguishable from it. (*A. J. P.*, 1884, 185, and *Ph. Rund.*, 1883, 245; *A. Pharm.*, 1887, 183.)

Under the name of *perezol* the 0.5 per cent. alcoholic solution of *pipitzahoic acid* has been recommended by Duyk as an alkalimetrical indicator. By acids it is at once decolorized; with alkalies it becomes reddish. Boric, and perhaps other acids, and acetates, borates, bicarbonates, and carbonates act with respect to the solution like alkalies. For a paper on pipitzahoic acid by Altamirans, see *Analen del Instituto Mex.*, Nat. 7, p. 21, or *P. J.*, 1905, 553.

Periploca. *Periploca græca* L. *Silk-Vine.* (Fam. *Asclepiadaceæ.*)—From the bark of this deciduous shrub, growing in the neighborhood of the Black Sea, has been separated by Lehmann (*A. Pharm.*, 1897, p. 157) a colorless glucoside, *periplocin*, $C_{30}H_{48}O_{12}$, soluble in 125 parts of water, freely soluble in alcohol. According to the experiments of Burschinski (*St. P. M. W.*, 1897), it is an active cardiac poison belonging to the digitalis group. It has been used as a cardiac tonic by Cholewa (*Th. M.*, 1904, p. 292), Silberberg (*In. Dis.*, Odessa, 1909), and others, in the treatment of *heart disease.* Silberberg asserts that it is better suited for intravenous injection than strophanthin. The *dose* is from one one-hundred-and-twentieth to one-sixtieth of a grain (0.0005–0.0011 Gm.).

Peronine. *Benzyl-morphine Hydrochloride.* $C_{17}H_{18}NO_2.O.C_6H_5CH_2HCl$.—This is the hydrochloride of morphine benzyl-ester, produced by replacing the hydrogen of the hydroxyl group in morphine, which is analogous to the hydroxyl group of phenols, with the alcohol radical ($C_6H_5CH_2$). *Peronine* occurs as a bitter, odorless, white powder, consisting of prismatic crystals. At 65.5° C. it dissolves in water in the proportion of 7.5 to 1000, but dissolves readily in 10 parts of boiling water, the aqueous solutions having a bitter taste and being neutral to litmus. It is soluble in 218 parts of 95 per cent. alcohol. Although precipitated from its solutions by the general alkaloidal reagents, peronine differs both in its solubilities, and also in its behavior towards special reagents, from morphine and codeine.

Peronine was first therapeutically investigated by Schröder (*Th. M.*, 1897), and the conclusion reached that in its medicinal activities it is intermediate between morphine and codeine. The physiological action of the drug has been partially studied by Mayor (*Revue Méd. de la Suisse Romande*, 1898), who finds that it produces in guinea-pigs and rabbits exaggerated reflexes, ending, if the dose have been large enough, in convulsions and death by asphyxia. The lethal dose for rabbits, according to Mayor, is 2.5 Gm. per kilo, or little less than one-third that of codeine. On the other hand, Pierart affirms, as the result of his experiments, that peronine is more poisonous than morphine. Clinically, peronine has been used to some extent as a substitute for morphine, having analgesic and hypnotic powers inferior to those of that alkaloid, but being of distinct value in the treatment of *phthisis, chronic bronchitis,* and other pulmonary diseases. The *dose* is from one-third of a grain to one grain (0.021–0.065 Gm.).

According to Bufalini, confirmed by Gevaert, the 1 to 2 per cent. solution of peronine placed in the conjunctival sac produces a complete anesthesia which lasts for many hours. The drug, however, has not been used for this purpose on account of its causing pain, edematous swelling, and even serous chemosis of the conjunctiva.

Peroxides.—There have been introduced into medicine a series of superoxygenated compounds with various inorganic bases. The theoretical basis for the introduction of these compounds into medicine is that in the presence of water they part with an atom of their oxygen, which unites with the elements of the water to form hydrogen peroxide, as in the following reaction:

$$MgO_2 + H_2O = MgO + H_2O_2$$

and that the hydrogen peroxide which is formed under these circumstances will exercise the well-known disinfectant properties of that substance. It is to be remembered, however, that hydrogen dioxide is very unstable in the presence of an alkali, and since, in the above reaction, an alkaline salt is left behind, there will be a rapid decomposition of the hydrogen dioxide, with the liberation of free oxygen. The more highly alkaline the oxide which is left after the splitting off of one atom of oxygen, the more rapidly will the resulting hydrogen dioxide be broken up. Of this group of salts, the sodium perborate has received official approbation, and the following are of sufficient importance to deserve mention.

Magnesium Peroxide. Magnesii Peroxidum. N. N. R. 1924.—*Magnesium dioxide* is an odorless, white powder, practically insoluble in all the ordinary solvents. It should contain not less than 15 per cent. of MgO_2 equivalent to 4.3 per cent. of available oxygen. It has been used as an antiseptic with asserted good results in the treatment of gastric and intestinal disorders, but it does not seem probable that whatever benefit may have followed this treatment can be laid to the disinfectant properties of the drug. It will, in these cases, evidently act as an antacid and laxative as does the ordinary magnesium oxide. It has also been used internally as a substitute for the ordinary oxide in the treatment of *rheumatism, gout* and *hyperacidity of the stomach,* and also, with less reason, in the treatment of *diabetes.*

Although the germicidal power of magnesium peroxide has not been as yet satisfactorily determined, the experiments of Park indicate that it is a germicide of considerable power. Croner states that the addition of 0.7 Gm. of magnesium peroxide per liter drinking water exercised a bactericidal effect, but did not produce complete sterility of the water. It has been used locally as a dusting powder in infectious conditions of the throat, such as acute *tonsillitis,* but chiefly as an ingredient of dentrifrices. Magnesium peroxide is also known under various brand names, such as *Magnesium Perhydrol, Magnesium Superoxyl, Biogen, Novozone,* and *Magnodat.* The *dose* for internal administration is from five to twenty grains (0.32–1.2 Gm.).

Sodium Peroxide. N. N. R. 1924.—This occurs as a white or yellowish powder which dissolves in water with the development of heat and the evolution of oxygen. It should contain at least 90 per cent. of Na_2O_2, equivalent to 18.4 per cent. of available oxygen. It is largely used as a bleaching agent in the arts and is also used by dentists for bleaching teeth. Unna recommends a sodium peroxide soap made of 3 parts of liquid petrolatum, 7 of dried soap, and from 2½ to 7 per cent. of sodium peroxide. It is said to impart to a pale and excessively cornified facial skin pitted with comedones, a healthy, rosy color and a softened surface. It has also been used in *rosacea pustulosa.* A proprietary preparation of fused sodium peroxide, containing also some catalytic agent is sold under the name of *oxone.*

Calcium Peroxide. N. N. R. 1924.—*Calcium Peroxidatum* or *gorit,* CaO_2, occurs as a cream colored, odorless and tasteless powder, which is practically insoluble in water. The standard of the N. N. R. requires 60 per cent. of CaO_2 corresponding to 13.3 per cent. available oxygen. It is chiefly used as an addition to dentifrices, but often in such small quantities as to be absolutely incapable of any antiseptic action in the mouth. It has also been used as an antacid and disinfectant in gastric and intestinal disorders in *doses* of five to fifteen grains (0.32–1.0 Gm.).

Strontium Peroxide. N. N. R. 1924.—This is a white, odorless and tasteless powder containing at least 84 per cent. of SrO_2, equivalent to 11.2 per cent. of available oxygen. It is almost insoluble in water. It is employed in medicine as a dusting powder and in the form of an ointment.

Zinc Peroxide. N. N. R. 1924.—This occurs as a white or yellowish insoluble powder, representing at least 45 per cent. of ZnO_2, equivalent to 7.4 per cent. of available oxygen. It is used in medicine as an antiseptic in various ulcerated conditions, such as *burns,* old *leg ulcers,* and the like. It has been recommended as a local application in various *skin diseases.* It may be used either mixed with talc as a dusting powder, or in the form of an ointment in strengths of 5 to 25 per cent. *Ektogan, Zinc Perhydrol,* and *Zinconal* are proprietary forms of zinc peroxide.

Persulphates.—Persulphates are obtained by the electrolysis of solutions of sulphates. Sulphuric acid is decomposed into H_2 and SO_4, and the SO_4 ion unites with a molecule of the normal sulphate, as:

$$Na_2SO_4 + SO_4 = Na_2S_2O_8.$$

They have been brought forward for use in medicine and dentistry on account of their germicidal properties and as a source of nascent oxygen. According to Friedländer (*Th. M.,* Feb., 1899), the half per cent. aqueous solution checks the growth of pathogenic bacteria, and the 5 per cent. solution kills them. They are said to be actively poisonous, 0.5 gramme per kilo rapidly causing death in the rabbit, and to be violently irritant to mucous membranes; one and one-half to five per cent. solutions have been used to some extent in the dressing of *wounds.*

The important persulphates are *ammonium persulphate,* $(NH_4)_2S_2O_8$, which occurs in colorless crystals, making a turbid solution with water; *potassium persulphate,* $K_2S_2O_8$, which occurs in colorless crystals, very slightly soluble in water; and *sodium persulphate,* $Na_2S_2O_8$, a colorless crystalline powder, sparingly soluble in water.

Sodium persulphate has been recommended internally as an aperitive stimulant to digestion, in *hypochondria, chlorosis,* and *neurasthenia.* Lumière (*Lyon Chirurgical,* October, 1915) has found sodium persulphate useful in the treatment of *tetanus.* From experiments in the test tube as well as in the lower animals he concludes that its effect is due to the destruction of the toxin. It has been used in various intestinal conditions as a stimulant and antiseptic. Cannaday (*Press. Med.,* 1905, p. 286) reports favorably upon its action in *typhoid fever.* The *dose* in a day is three grains (0.2 Gm.).

Persodine is the one and three-tenths aqueous solution which has been supplied commercially in France.

Ammonium persulphate has been strongly recommended by Strzyzowski (*Schweizer Wochen. f. Chemie u. Pharmacie,* 1898, No. 48) as a urinary reagent; if its ten per cent. solution is poured down the inside of a test tube containing urine the presence of albumin will be revealed by a whitish-gray zone at the juncture of the two liquids. The development of a green tint indicates the presence of biliary pigments. The salt is readily soluble in water, and its solutions keep unchanged for weeks unless they be heated or in contact with easily oxidizable bodies. (*Th. M.,* 1899, 99.)

Pertonal. *Acetyl-amido-ethoxybenzene.*—This compound is said to resemble acetphenetidin in its action but to be less depressant (*A. J. P.,* 1919, xci, 365). *Dose,* ten to twenty grains (0.6–1.2 Gm.).

Perugen.—A synthetic imitation of Peru balsam obtained through solution of aromatic gum resins and balsams in aromatic esters. It behaves similarly to the true balsam in its action towards solvents, etc., but can be distinguished by the difference in its lower saponification number and iodine number, that of *perugen* being 206 and 33.7, respectively.

Petroleum. *Rock Oil. Oleum Petræ. Huile minéral,* Fr. *Bergöl,* G.—*Petroleum* is a native mixture of hydrocarbons with very small amounts of oxidation or alteration products admixed. The hydrocarbons may be gaseous, liquid, or solid, and in crude oil, fresh from the wells, all three classes are present. The hydrocarbons belong to several of the homologous series known to organic chemistry. The researches of Pelouze and Cahours, of

Warren, and more especially of Schorlemmer, have established the presence of the paraffin series, C_nH_{2n+2}, beginning at methane and continuing through the liquid members, which constitute the bulk of the oil, to the solid hydrocarbons known commercially as "paraffine"; of the olein series, C_nH_{2n}; of the benzene series, C_nH_{2n-6}. After the oil has been heated, as in distillation, pyrogenic products form, so that in the residues of petroleum, distillation, naphthalene, anthracene, and other higher hydrocarbons have been detected. In Caucasian petroleum, Beilstein and Kurbatow (*A. J. P.*, 1880, 612) have also found another homologous series of hydrocarbons, *hexahydrobenzene*, C_6H_{12}, and its homologues known as the *naphtenes*. These same hydrocarbons under the name of *polymethylenes* have been shown by Richardson to make up California petroleums and to be present in other asphalt base oils.

Pennsylvania petroleum consists in great part of paraffins, and the individual hydrocarbon making the bulk of illuminating oil is *heptane*, C_7H_{16}. The oxidation products accompanying petroleum constitute usually only a small fraction of 1 per cent., and have not been very fully studied. It is known, however, that these alteration products are largely acid in character. Prolonged atmospheric exposure may, however, cause a petroleum to thicken, at least superficially. In this way the semi-solid deposits of California are explained, as well as Rangoon tar and Trinidad pitch or bitumen. When the bitumen is in the solid state it is called *asphaltum*. This is black and sometimes dry, friable, and is insoluble in water or alcohol. Not infrequently asphaltum exists in nature mixed with more or less of the liquid substance, and this semi-solid mixture is distinguished by the name of *maltha* or *mineral tar*.

Petroleum has been known from the earliest historical period. Within the limits of the United States it has long been known to exist in a few localities. On the borders of Seneca Lake in the State of New York small quantities of it were collected, and to some extent used in medicine under the name of *Seneca oil* in colonial days. In Western Pennsylvania, on Duck Creek in Ohio, near Scottsville in Kentucky, and on the Kanawha in Virginia, it attracted local attention, and a certain locality in Western Canada had acquired some notoriety by its burning spring. But little attention was paid to it until the year 1859, when, the preparation of oil for burning, distilled from bituminous shales, having proved very profitable, and a strong resemblance having been shown to exist between this and petroleum, enterprise was directed towards some of the known resources of the latter liquid, and, being greatly stimulated by success, soon led to further and astonishing discoveries. At first the most productive locality of petroleum was in Western Pennsylvania; but it is now obtained in many States. After the Pennsylvania field, in order of development, is that of Ohio; but most of the oil produced in this State is from a different geological horizon—viz., the Trenton limestone—and contains a persistent sulphur impurity. This renders the Ohio oil (popularly known also as *Lima oil*, from the town of Lima, Ohio) more difficult and expensive to refine. It is hence very largely used in the crude state as *fuel oil*, and as such has been of the greatest industrial value, being shipped by pipe line or tank cars to great distances. Within recent years large quantities of petroleum have been found in California, Texas, Louisiana, Kentucky, and Kansas, but in the main it is of a grade much inferior to that known as Pennsylvania oil, being largely used as fuel oil. Petroleum is found in commercial quantities in many parts of the earth. The more important oil-fields are in various sections of the United States, Mexico, Russia, Mesopotamia, India, etc.

In the early days of the petroleum discovery the oil was gathered as it floated on the surface of the water in springs or small streams. In 1859 the first oil well, the Drake well, was sunk near Titusville, Pa., and the oil-bearing strata were reached at a depth of seventy-one feet, with the result of some eight barrels per day. In 1861 and 1862 the first large flowing wells were struck in drilling for oil. The explanation of these flowing wells is simply that in new territory the gaseous hydrocarbons have accumulated with the liquid oil in such amount that they exert an enormous pressure, causing a flow of oil of several thousand barrels per day. Often, however, the pent up gas escapes with enormous force without any accompanying oil. These *gas wells*, as they are termed, are well known througout the oil regions, and they have been utilized on a large scale as sources of gaseous fuel for manufacturing and domestic purposes. Sadtler has analyzed numerous samples of this *natural gas*, and finds it to consist chiefly of methane and its homologues, with traces of the olefines and of carbon monoxide. In one case free hydrogen was present. (*Proc. Amer. Philos. Soc.*, xvi, 585, 1877.) After a well has flowed oil for a time, it will continue to yield on pumping. Indeed many smaller wells never have flowed, and have to be pumped from the start. In some districts "torpedoing" with nitroglycerin has been largely resorted to after a well has begun to decline in power, in order to increase the flow. The explosion effects this by shattering the sandstone and pebble conglomerate which holds the oil, so that new channels are opened.

Oil wells are of various depths. The first or Drake well, as stated, was only seventy-one feet deep, while in Washington County and other localities in the southwestern part of Pennsylvania the oil was obtained from a depth of 2000 feet.

There are two theories as to the origin of petroleum. According to one, it is simply a product of distillation from the bituminous shales which underlie almost the whole of this oil producing country. The gas and the liquid oil are equally products of this distillation. According to the other, it represents the decomposition of marine plants and animal life which accumulated in these sand rock formations. These decomposition products may have also been in part subjected to distillation. Studies by Engler (*B. Chem. G.*, 1888, 1816) on the distillation under pressure (ten atmospheres) of fish oils and of olein and other fats show that large amounts of light oils, composed of pentane, hexane, heptane, octane, and nonane, can be obtained, thus making the second theory very probable. S. P. Sadtler has shown that linseed oil, distilled under pressure, may be made to yield hydrocarbons of the paraffin series, and has obtained products of all gravities from light benzin to solid scale paraffin. Thus, Engler's theory must be broadened sufficiently to allow of the vegetable seed oils being taken as original sources of petroleum production as well as animal oils.

Crude petroleum is occasionally of a clear color when taken from the earth, but is generally of a greenish color, appearing claret-red by transmitted light. The green color may, however, become so dark as to be almost black. In gravity it varies from 0.865 to 0.777, or from 32.5° to 52° Baumé.

The method of purifying petroleum is analogous to that already described for purifying coal tar. The crude oil is put into large retorts of wrought iron and exposed to a heat rising gradually to between 315.5° C. and 426.6° C., by which all the volatile ingredients are distilled, leaving from five to ten per cent. of solid residue, constituting a sort of coke. The liquids thus obtained are comparatively colorless, though still retaining the strong odor of the crude oil. The several fractions are collected separately and show very varying gravity and volatility, and are applied to different uses. An average result of a normal distillation may be stated as follows: Gasoline 1½ per cent., refined naphtha 10 per cent., benzin 4 per cent., refined petroleum or kerosene (sometimes called coal oil), 55 per cent., lubricating oil 17½ per cent., paraffin 2 per cent., loss, gas, and coke 10 per cent. As the greater demand for illuminating oil makes it desirable to get the maximum quantity of this fraction, the distillation is generally so conducted that by the process of "cracking" the yield of burning oil is increased at the expense of the lubricating oil and heavy naphtha. Many distilleries obtain, therefore, from 75 to 80 per cent. of illuminating oil from the crude material. A crude distillate, however, would not be adapted for the purposes of an illuminating oil, so the distillate must be treated with acid. It is placed in the treating tank or "agitator" and 1 or 2 per cent. of strong sulphuric acid is added, when, by the aid of an air blast introduced below, the whole is violently agitated. The acid combines with the impurities of the oil and forms a tarry substance, called "*sludge acid*," which settles to the bottom and, after the whole has subsided, is removed. The oil is then washed with water and again agitated, the process being repeated once or twice. It is then treated with caustic soda solution and again washed. The oil is now clear and almost colorless. It is then placed in large settling tanks to allow the water to separate. If it does not have the desired fire test, it is "steam stilled" and the lighter vapors taken out until the desired test is obtained. In most States of the Union the legal fire test for illuminating oil is 43.3° C.; that is, it must not evolve inflammable vapors below the temperature of 43.3° C. Many special brands of illuminating oil have a much higher fire test, as high even as 148.8° C.

Lubricating oils, on the other hand, are valued according to their "cold test"; that is, they must not congeal except at very low temperatures. A lubricating oil, therefore, consists of the heavy liquid hydrocarbons of the paraffin and olefin series, but is free from the solid paraffin.

Medicinal Properties and Uses.—Petroleum has been deemed a stimulating antispasmodic, expectorant, and diaphoretic. In large quantities it may prove poisonous, as shown by a case recorded in the *J. P. C.* (March, 1869, 227), in which, after swallowing by mistake a quantity of rectified petroleum, a workman was seized almost immediately with violent inflammation of the throat, with colicky pain, and a desire to vomit, followed in an instant by a fearful tetanic seizure, and a general rigidity, attended by the most frightful cries. After a relaxation of ten minutes the symptoms returned with still greater violence; and life was probably saved only through the prompt action of the powerful emeto-cathartic medicines administered.

Bjerrum (*Ugeskrift for laeger*, Copenhagen, June 27, 1918) reports death in a child of fifteen months from drinking a quantity of petroleum, estimated at 4 or 5 Gm. There was violent vomiting soon after the petroleum was ingested, but the child died within a few hours with symptoms of heart failure.

The more volatile fractions of petrolatum are also highly poisonous to insect life and various distillates under trade names are sold as insecticides.

Petroleum is used as a folk remedy in the treatment of acute *bronchitis*, but probably with no beneficial action in this condition save by virtue of its nauseating effect. The inhalation of asphalt vapors have been recommended by Floer (*Ther. Geg.*, 1909, p. 405) in the treatment of *pulmonary tuberculosis*. It is stated that the influence of these fumes is not merely upon the bronchial mucous membranes, but that there is a marked improvement in the appetite and in the digestive power. In Germany it has been used successfully as a remedy against the *tape worm*. Schwartz's formula in such cases is a mixture of one part of petroleum with one and a half parts of tincture of asafetida, of which forty drops were given three times a day. Externally, petroleum is employed in *chilblains*, *chronic rheumatism*, affections of the joints, *paralysis*, and diseases of the skin, and is said to be very effectual in *psora* and *prurigo*. (See also *Petrolatum* and *Petrolatum Liquidum*.) It is an ingredient in the one time popular remedy called *British Oil*. It is affirmed that many cases of *asthma* are much benefited by inhaling petroleum vapors.

The lighter fractions of petroleum are capable of absorption and are highly toxic substances. There have been a number of cases of serious and even fatal poisoning reported both from the swallowing and inhalation of various products of this nature. The symptoms have been dizziness, cyanosis, rapid small pulse, respiration slow and labored. If the dose is large enough the patient becomes stuporous and occasionally delirious. When taken by the mouth to these symptoms are added gastro-intestinal irritation. H. C. Wood, Jr. (*Phila. Medical Journal*, 1899), has shown that the mixture known as benzin is a direct depressant to the heart and vasomotor system. Various of these substances are used by depraved humanity as intoxicants.

Extraordinary claims have been made for various commercial emulsions containing some form of petroleum, but there is no certain substantiation of these claims. The *dose* of petroleum is from thirty to sixty minims (2–4 cc.).

A water and alcohol soluble combination of petroleum oil has been originated by Max Doenhardt (*Ph. Ztg.*, 1913, p. 266), who discovered that when petroleum is mixed with terpineol and the solution treated with triolein and potassium hydroxide solution, the mixture develops heat spontaneously, a product resulting in a short time which forms a perfectly clear solution with alcohol, which in turn may be diluted with water to produce a permanently clear solution. The proportions of the ingredients depend upon the amount of petroleum, an excess of alkali always being necessary. The author has patented a product called "*Terpipetrol*" made by the above process.

Peucedanum. *Chucklusa. Hog Fennel. Sulphurwort.*—This is the root of *Peucedanum officinale* (Fam. *Umbelliferæ*), originally an European plant but now growing in North America. The active constituent of the root is *peucedanin*, $C_{16}H_{16}O_4$, stated to be diuretic and emmenagogue.

Peucedanum palustre Mnch. *Marsh Parsley. Marsh Smallage. Persil de Marais*, Fr. *Radix Olsnitii. Sumpfsilge, Elsenich*, G.—The root of this European umbellifer is, when dried, of a brown color externally, having a strong aromatic odor, and an acrid, pungent, aromatic taste. Peschier found it to contain a volatile oil, a fixed oil, and a peculiar acid which he calls *selinic*. It was formerly used for *epilepsy* in Russia. *Dose*, from twenty to thirty grains (1.3–2.0 Gm.).

Peucedanum sativum Benth. and Hook. which had been claimed to contain a volatile alkaloid by Wittstein has been reinvestigated by VanCook (*Pharm. Weekblad*, 1919, lvi, 1391) who claims to have found fatty material, starch, sugars, and small amounts of a non-volatile alkaloid which is present in all parts of the plant. There is also an ether soluble crystalline substance which is neither alkaloidal nor glucosidal.

Phaselin.—This substance is represented as the active constituent of the bean of *Dilkas Mexicano*, a South American plant. It is used similarly to papain as a digestive in *doses* of eight to fifteen grains (0.5–1.0 Gm.).

Phaseolus. *Phaseolus vulgaris* L. *Common Kidney* or *String Bean*. (Fam. *Leguminosæ*.)—Of this species there are some 70 cultivated varieties. Soltsien found an alkaloid, *phaseoline*, in the legumes of the common bean. He, during a toxicological analysis, traced the source of the alkaloid which might, under other circumstances, have been mistaken for a ptomaine, to the beans found in the stomach under examination. The new substance is not crystallizable in the free state, but it crystallizes as a hydrochloride. (*A. Pharm.*, 1884.)

According to Dunlop (*P. J.*, 1917, xcviii, 257) the *Phaseolus lunatus* L. (*Civet Bean*), from a variety of which we derive the well-known *lima bean*, produces also a variety having a dark purple bean (*Java Bean, Burma Bean*), which is highly toxic. The toxicity of this bean depends upon the presence of *phaseolunatin*, $C_{10}H_{17}O_6N$, a cyanogenetic glucoside which forms prussic acid in the stomach.

Phenacaine.—There is formed by the condensation of molecular amounts of phenacetin and paraphenetidin, a base known as *Holocaine*. This is *p-Diethoxyethenyl diphenylamidine. Phenetidylacetphenetidin*,

$$C_6H_4\begin{cases}OC_2H_5\\NH.C.(CH_3)=N.C_6H_4(OC_2H_5).\end{cases}$$

The free base crystallizes well, is insoluble in water, and melts at 121° C. It is insoluble in fixed oil, a point which should be borne in mind, inasmuch as it is a frequent method of using holocain to prescribe it in a castor oil solution. The hydrochloride is, however, soluble in oils and should be dispensed when the other is called for. It should not be dispensed in alkaline solutions, being rapidly decomposed.

Phenacaine (*Holocaine*) *Hydrochloride*, *N. N. R.* 1924, forms colorless, lustrous, odorless crystals, melting at 189° C. It is soluble in 50 parts of water and readily in alcohol. It readily dissolves in boiling water, leaving on cooling a saturated solution containing about 2½ per cent. of the hydrochloride. This solution is slightly bitter, neutral in reaction, and keeps many months without change. In boiling, a porcelain vessel should always be used, as the solution at 100° C. is affected by the alkalinity of the glass.

Phenacaine is used chiefly as a local anesthetic for the eye. Although Eggleston and Hatcher (*J. A. M. A.*, Oct. 25, 1919, p. 1256) have shown that it is one of the most poisonous of the cocaine group of local anesthetics this fact is of small moment in ophthalmological practice because of the minute quantities of the drug required. The advantages claimed for it in ocular practice (see *J. A. M. A.*, 1921, lxxvii, 1730) are that its action is quicker than that of cocaine, that it does not dilate the pupils nor dry the cornea and that it is distinctly antiseptic. It is usually applied in 1 per cent. solution. According to the experiments of Heinz and Schlosser (*Klin. Monat. f. Augen.*, xxxv, 1897), the ½ of 1 per cent. solution affects bacteria, while the 1 per cent. solution is a powerful germicide, rapidly killing the lower organisms, including infusoria. Even in small doses it causes in frogs and in mammals violent convulsions which appear to be of cerebral origin, since after division of the spinal cord in the mouse the convulsions were confined to the anterior portion of the body. Holocaine is an active muscle poison, the 1 per cent. solution rapidly killing voluntary and cardiac muscles in the frog, and it exerts also a curare-like influence upon the motor nerves. According to Winselmann, its 1 per cent. solution exceeds in anesthetic power the 3 per cent. solution of cocaine.

Phenegol. $C_6H_5(O.NO_2.SO_3K):Hg:(KSO_3.NO_2.O)C_6H_5$.—Nitrated derivatives of paraphenolsulfonic acid unite readily with mercury, forming compounds known as *egols*. According to the phenol selected these products are called *phenegol*, *cresegol* or *thymegol*. Phenegol is a red-brown, soluble, tasteless powder, containing one-third mercury. It is asserted to be free from irritating action, and to be germicidal in 0.4 per cent. solution.

Phenoco. *N. N. R.* 1924.—This compound is said to be a mixture of coal tar creosote and higher phenol homologues suspended in a soap solution. It contains 8 per cent. phenol homologues. With water it forms a milky white emulsion of a high antiseptic value. The phenol coefficient test showed a germicidal value over 15 times that of phenol. (*U. S. Hygiene Bull.*, vol. viii, No. 1, 1911.) It is used in dilutions of 0.1 to 0.5 per cent.

Phenocoll. *Amido-aceto-para-phenetidin. Glycocoll-para-phenetidin. Phenamine.*

$$C_6H_4\begin{cases}OC_2H_5\\NH.COCH_2NH_2H_2O.\end{cases}$$

—This is formed by the action of glycocoll (amidoacetic acid) upon phenetidin. It is a white, finely crystalline powder, soluble at 17° C. in sixteen parts of water; also soluble in warm alcohol. The hydrochloride of phenocoll has almost entirely displaced the base as a therapeutic agent. Ammonia, alkalies, and alkaline carbonates throw down the pure base phenocoll from the solution of the hydrochloride, in the form of white needles with one molecule of water of crystallization.

Phenocoll closely resembles the other phenetidin compounds in its physiological action. Hertel and Herzog (*D. M. W.*, 1891) find that its antipyretic action is prompt, and that the sweating which is a common accompaniment may be readily controlled with small doses of atropine. Antiperiodic powers have also been attributed to it, but without any convincing evidence. The *dose* of the hydrochloride is from eight to fifteen grains (0.5–1.0 Gm.).

Phenocoll Salicylate, Salocoll,

$$C_6H_4\left\{\begin{array}{l}OC_2H_5\\NH.COCH_2.NH_2.C_6H_4(OH)COOH,\end{array}\right.$$

has been put upon the market as an antirheumatic. It may be used in the *doses* of ten to twenty grains (0.65–1.3 Gm.).

Phenoltetrachlorphthalein. *N. N. R.* 1924.—This dyestuff is made by the condensation of phenol with tetrachlorphthalic acid. It differs in its composition from the official phenolphthalein in having four chlorine atoms in the place of four of the hydrogen atoms.

It occurs as an odorless pink powder practically insoluble in water but soluble in alcohol or acetone. In alkaline solution it dissolves forming purple—or, when very dilute, bluish—solutions. This enables it to be easily distinguished from phenolphthalein which forms red solutions.

Phenoltetrachlorphthalein was suggested some years ago as a hypodermic purgative (see Abel and Rowntree, *J. P. Ex. T.*, 1909, i, p. 231) but did not achieve popularity for this purpose. As it was found to be excreted from the blood almost exclusively by the liver, it has been used to a very considerable extent as a test of the functional activity of the liver. The test is performed by injecting the disodium salt, intramuscularly or intravenously—the recommended *doses* have ranged from one to six grains (0.06–0.4 Gm.)—and afterwards estimating the amount of the dye either in the feces (Rowntree, *J. A. M. A.*, 1914, lxiii, 1533), in the duodenal contents (Aaron, Beck and Schneider, *J. A. M. A.*, 1921, lxxvii, 1631) or in the blood (Rosenthal, *J. P. Ex. T.*, 1922, xix, 385).

Phenoval. *Fenoval, Bromvaletin,* alpha-bromisovaleryl-phenetidin.—This occurs as tasteless, odorless crystals insoluble in water. It has been recommended as an hypnotic and anti-neuralgic, in *doses* of from eight to thirty grains (0.5 to 2 Gm.).

Phenoxycaffeine. $C_8H_9(OC_6H_5)N_4O_2$.—This product forms a white, crystalline powder, fusing at 142° C. It is used as an analgesic in neuralgias in *doses* of four to five grains (0.26–0.32 Gm.).

Phenoxy-proprandiol. *Glycerine-monophenylether. Antodyne.* $C_6H_5OCH_2CHOH.CH_2OH$.—This occurs as white crystals, freely soluble in both water and alcohol, and melting at 69° to 70° C. It is used as an analgesic in *neuralgia, gonorrhea, arthritis* and other painful conditions. It appears to differ from other coal-tar anodynes in that it is not antipyretic. The *dose* is from five to ten grains (0.3–0.6 Gm.).

Phenyform is a condensation product of phenol and formaldehyde, and occurs as a grayish, odorless powder, insoluble in water, but dissolving in alkaline solutions, or alcohol. It is asserted by Schuftan (*Th. M.*, 1906, 249) that phenyform is completely non-toxic. Brenning (*All. W. M. Z.*, 1906, 182) has used it as a dusting powder in various suppurating processes and states that it not only checks the formation of pus, but also acts as a deodorizer and favors the formation of healthy granulations. It has also been employed in *urethritis*, a finely powdered preparation being blown into the urethra, under which circumstances it is asserted that it adheres firmly to the mucous membranes.

Phenylchinoline. *Phenylquinoline.* $C_9H_6(C_6H_5)N$.—According to Tappeiner (*D. A. K. M.*, lvi, 1896), the action of this substance on the lower organisms is almost identical with that of quinine and about equal to it in strength.

Phenylenediamine. $C_6H_4(NH_2)_2[1{:}4]$.—*Paraphenylenediamine* and *meta-phenylenediamine* have been physiologically studied by Dubois and Vignon (*C. R. A. S.*, cvii, 533), who find that in *doses* of 0.01 Gm. per kilogramme it causes in the dog vomiting, diarrhea, and fatal coma, with peculiar symptoms.

Under the name of *ursol* and various other trade names paraphenylene-diamine has been used for dyeing the hair and coloring furs. This has given rise to a large number of cases of violent dermatitis, accompanied by itching and burning, in some cases much edema of the skin so that the eye-lids may be almost completely closed; the inflammation is not limited to the areas with which the irritant comes into direct contact. According to Olson (*J. A. M. A.*, March 18, 1916) the irritation is due to an intermediary product of oxidation of the dye, *quinone dichlor-diamin.* According to Blaschko (*D. M. W.*, 1913, xxxix, 2406) sufficient of the dye may be absorbed through the skin to give rise to constitutional symptoms such as vomiting, vertigo, ringing in the ears, etc. Gibbs (*J. P. Ex. T.*, 1922, xx, 221) has shown that when administered internally it causes a remarkable edema of the head and neck; doses of 1 Gm. per kilo proving fatal, in the cat, from pulmonary edema. He suggests that these effects may be due to a disturbance of the colloidal balance of the blood. Thompson (*N. Y. M. R.*, 1920, xcvii, 401) reports a case of constitutional poisoning with vertigo, diplopia and violent dermatitis from the use of a hair dye of this type. (For literature on this subject see Knowles, *Penna. M. J.*, Sept., 1916; also see Nostrum and Quackery, *A. M. A.*, vol. i.) Colman and Loewy (*D. M. W.*, 1911), however, have found that by combining it with reducing substances, the toxic properties of paraphenylenediamine were reduced. They recommend as a hair dye a solution of *paratoluylenediamine* with neutral sulphites, which is put upon the market under the name of *primal.*

Phenylhydrazine. $C_6H_5NH.NH_2$.—This is prepared from diazobenzene hydrochloride (resulting from the action of sodium nitrite upon aniline hydrochloride) by reduction with stannous chloride or sodium sulphite. The various compound derivatives of this substance have been tested by Heinz (*B. K. W.*, 1890) and others, and found to be too toxic for use in practical medicine. Phenylhydrazine is a colorless, slightly yellowish, highly refractive liquid, while the hydrochloride is a white crystalline powder, melting at about 200° C. *Phenylhydrazine hydrochloride* has been employed as a test for sugar in the urine. (*Fischer's Test.*) (See *Diagnostic Reagents.*)

Phenylhydrazine is an active irritant and toxic agent, producing in warm-blooded animals violent disturbances of breathing, with gastro-enteritis. It is remarkable for the changes which it produces in the blood, causing that fluid to become of a distinct green color when seen in thin sheets. The coloring matter appears not to be due to a derivative of phenylhydrazine, but to have at least spectroscopic relations to acid hematoporphyrin and to chlorophyll. (See *Z. B.*, N. F., xxiv, 1901.)

Phenylhydroxylamine. $C_6H_5.NH.OH$.—This substance has no known application to the treatment of disease, but requires notice on account of the occasional poisoning by it of those who are engaged in the manufacture of certain chemicals. For cases, see Hirsch and Edel (*B. K. W.*, xxxii, 1895), L. Lewin (*A. E. P. P.*, Bd. xxxv). The symptoms, which have developed with great suddenness, have consisted of coma, cyanosis, pulselessness, abolition of corneal and pupillary reflexes, chocolate-colored blood, methemoglobinuria, grayish-blue lips, and intense blue-red surface of limbs. The treatment of these cases should consist in active artificial respiration, together with hypodermic injections of strychnine and of digitalis.

Phenylurethane. *Euphorin. Ethyl Phenylcarbamate. Carbamilic Ether.* $C_9O_2H_{11}N$, or $CO\left\{\begin{matrix}OC_2H_5\\NH(C_6H_5)\end{matrix}\right.$.—This is a white, crystalline substance, having an aromatic odor and clovelike taste, and is made by the action of ethyl chloroformate (or ethylic ether) on aniline. It is almost insoluble in cold water, very soluble in boiling water, alcohol, and ether, and melts at 51° C. It has been physiologically investigated by Giacoasa, who finds that its 2 per cent. solution is antiseptic and that its toxicity is low but in large doses it depresses the central nervous system. It has been used by Sansonia (*Th. M.*, 1892, p. 452) as an antiseptic in obstinate *ulcers*, and in chronic *ophthalmia*, and by others in the treatment of *rheumatism*, but it has failed to establish its value in these conditions. Stroll (*M. M. W.*, 1907, p. 2262) has asserted that it is an extraordinarily powerful local anesthetic, and of great service in painful *ulcers* of the foot.

The similarity of names has led to euphorin being confused with europhen. *Dose*, eight to fifteen grains (0.5–1.0 Gm.).

Phlorizin. *Phloridzin. Phlorrhizin. N. N. R.* 1924. $C_{21}H_{24}O_{10} + 2H_2O$.—This is a bitter principle, discovered by De Koninck, of Germany, in the bark of the apple, pear, cherry, and plum trees. It is most abundant in the bark of the root, and derived its name from this circumstance (from two Greek words, φλοιός, bark, and ῥίζα, a root). It is light, white, crystallizable in silky needles, of a sweet, afterwards bitter taste, soluble in about 1000 parts of cold and freely soluble in boiling water, very soluble in alcohol and methyl alcohol, scarcely soluble in ether, cold or hot, dissolved without change by solutions of the alkalies. It loses its water of crystallization at 100° C., and fuses at a somewhat higher temperature. The ammoniacal solution becomes red on exposure to the air on account of the formation of *phlorizein*, $C_{21}H_{30}N_2O_{13}$ Phlorizin is a glucoside. When heated with diluted hydrochloric or sulphuric acid, it is converted into sugar and a peculiar substance called *phloretin*, $C_{15}H_{14}O_5$. To obtain phlorizin, the fresh bark of the root of the apple tree should be selected, as the dried bark is said to contain it in much smaller proportion. It is obtained by extracting the bark with boiling water and allowing the glucoside to crystallize out by cooling; the crude substance later being purified with animal charcoal. Rochleder states that the leaves contain a principle, *isophlorizin*, isomeric with phlorizin.

When given to the lower animals in very large doses (from seven to ten grains to the pound), phlorizin produces polyuria and glycosuria. (See Coolen, *Archiv. de Pharmacod.*, vol. ii, 1896; also Kossa, *Z. B.*, xl, 1900.) These effects are due to an irritant action on the kidney. Leclerq (*Paris Médical*, 1919, ix, 248) has used phlorizin, in *doses* of 5 to 10 milligrammes (one-twelfth to one-sixth grain), as a diuretic. Formerly it was considerably employed as a test of renal efficiency but has been latterly supplanted by various dyes. (For further information see *U. S. D.*, 20th edition, p. 1547.)

Phloroglucin. *Phloroglucinol.*—This is a trihydroxybenzene and therefore isomeric with pyrogallol. "It occurs as a white to cream colored crystalline powder readily soluble in water, alcohol or ether. When rapidly heated it melts between 217° and 219° C., when slowly heated between 200 and 209° C. Introduce a few crystals of phloroglucinol in a test tube with about 1 cc. each of sulphuric acid and acetic anhydride and heat in boiling water for from 5 to 10 minutes; no blue color develops (diresorcinol)." *U. S. IX.* Phloroglucin is used as a test for hydrochloric acid in the gastric contents (see under *Diagnostic Reagents*).

Phosphorescent Powder or Paint.—Made by mixing calcined oyster shells, 100 parts; caustic lime, 100 parts; calcined sodium chloride, 25 parts; then incorporate about 55 parts of sulphur and from 8 to 18 parts of calcium, barium, strontium or magnesium sulphide. It may be used as a paint by mixing it with varnish. If the substance has been exposed to sunlight, it becomes luminous in the dark. Radio-active substances are now used for this purpose as they do not require exposure to sunlight to render them luminous and are said to retain this property indefinitely. *Canton's phosphorus* consists of 2 parts of oyster shells and 1 part of sulphur.

Photoxylin.—This is a nitro-cellulose, which is said to be entirely soluble in a mixture of equal parts of concentrated ether and alcohol. According to Beringer, a 3 per cent. solution leaves on evaporation a very tough collodion-like film. *Photoxylin* is made from wood pulp, by methods of nitration similar to those given under pyroxylin, which is its chemical counterpart.

Physalis. *Physalis Alkekengi* L. *Alkekengi. Strawberry Tomato. Common Winter Cherry. Coqueret*, Fr. *Judenkirsche, Schlutte*, G.—A perennial herb belonging to the *Solanaceæ*, growing wild in Europe and Asia, cultivated in our gardens and said to be escaping locally. The fruit is a round red berry, about as large as a cherry, enclosed in the inflated calyx, and containing numerous flat kidney-shaped seeds. All parts of the plant are bitter, especially the leaves and the capsules enveloping the fruit. The berries are very juicy, and have an acidulous, bitter taste. By drying they shrink, and become a brownish-red color. Dessaignes and Chautard found a yellowish, bitter principle, *physalin*, very slightly soluble in cold water and freely soluble in alcohol and chloroform, especially with the aid of heat. Its composition is $C_{14}H_{16}O_5$. (*J. P. C.*, 3e sér., xxi, 24.) The berries are said to be aperient and diuretic, and have been recommended in *suppression of urine, gravel*, and *gout*. An extract of alkekengi berries to which lithium salt has been added is sold under the name of *lithal*. From six to twelve berries, or half an ounce of the expressed juice, may be taken for a *dose;* and much larger quantities are not injurious. They are consumed to a considerable extent in some parts of Europe as food and are coming into use to a certain degree for this purpose in America.

The berries of *Physalis viscosa* L., of this country, are said by Clayton to be diuretic.

Physostigmine Borate. *Eserine Borate.*—This eserine salt is advanced by Merck as possessing the advantage over the sulphate or salicylate of forming permanent aqueous solutions that do not become irritant. Its uses are the same as those of other eserine salts. (See Part I.)

Physostigmine Sulphite. *Eserine Sulphite.* $(C_{15}H_{21}O_2N_3)_2H_2SO_3$.—This salt of physostigmine has been brought forward as being more permanent than either the sulphate or salicylate. Its uses are precisely the same as those of the official salt. (See Part I.)

Phytelephas.—*Phytelephas macrocarpa* Ruiz. and Pav., or *negrito-palm*, of Colombia, Venezuela and Ecuador, yields the *Tagud nut*, from which is derived the hard white substance, *vegetable ivory* or *corajo*. The nuts contain a fixed oil. The ground nuts have been used as an adulterant in ground coffee and cattle powders. They may be detected in these by their endosperm cells which have extremely thick walls of reserve cellulose.

Phytin. *Calcium-magnesium Salt of Anhydro-oxymethylene-diphosphoric Acid.* $(C_2H_6O_9P_2)_2$-MgCa.—It is a white powder, slowly soluble in water, with a somewhat acid taste. Phytin, which was discovered in 1900 by Posternak (*C. R. S. B.*, lv, p. 1190), who has obtained it from the seeds of the hemp, sun-flower, sesame, peas, beans, and other plants. So universal is its distribution that he believes it an ingredient in all seeds, bulbs, and roots, and that it represents 70 to 90 per cent. of the entire phosphorus content of the plant seeds. It contains 22.8 per cent. of phosphorus. It is a heavy white powder, which when rubbed up with water forms a milky emulsion which is almost without taste.

Phytin was introduced into medicine on the supposition that being an organic form of phosphorus it would be more readily assimilated by the system, but the experiments of Mendel and Underhill (*A. J. Phys.*, 1906, xvii, 75), who find that it is eliminated as an inorganic phosphate, throw grave doubt on this supposition.

The preparation has been employed in *rickets, anemia, tuberculosis, neurasthenia* and other conditions in which phosphorus is useful. It is doubtful, however, whether this preparation possesses any very valuable therapeutic properties. The beginning *dose* is fifteen grains (1 Gm.) a day, given in divided doses.

Phytolacca Acinosa Roxb. (Fam. *Phytolaccaceæ.*)—This Asiatic plant has long been used in Japan as a diuretic, and is said to be violently poisonous. C. Nagai has separated from it an amorphous resin, *phytolaccotoxin*, which appears to be a spinal convulsant, and at the same time stimulant to the circulation, probably through the vasomotor centers. (*Sei-i-kwai Med. Journ.*, April, 1891.)

Pichurim Beans. *Semen Pichurim. Sassafras Nuts. Fèves Pichurim, Noix de Sassafras*, Fr. *Pichurimbohnen, Sassafrasnüsse*, G.—The seeds of *Nectandra Puchury-major* Nees, and of the *N. Puchury - minor* Nees (*Ocotea Puchury - minor* Mart.) (Fam. *Lauraceæ*), yielding respectively "*Fabæ Pichurim majores,*" or larger pichurim seeds, and "*Fabæ Pichurim minores,*" smaller pichurim seeds. The two species are closely allied and both have been known to botanists as *Ocotea Pichurim* H. B. K. (*Laurus Pichurim* Willd.). The trees grow in Brazil, Guiana, Venezuela, and other parts of South America, and are sometimes spoken of as *Brazilian* or *South American Sassafras.* The seeds of commerce usually consist of the separated cotyledons. They are plano-convex, from 3 to 5 cm. in length and nearly 2 cm. in width. Externally they are smooth and blackish-brown, being internally light brown. They have an aromatic odor combining that of nutmegs and sassafras, and a spicy pungent taste.

Pichurim beans contain a fatty matter of the consistency of butter, consisting largely of *laurostearin*, and a concrete volatile oil, *pichurim camphor* which appears to be identical with *laurel camphor.* A liquid product brought from South America and known as the *native oil of laurel* or *sassafras*, is obtained by incising the trunk of the *Nectandra puchury.* This is believed to be the same as that with which the copaiba from Maracaibo is adulterated. It may be distinguished from copaiba by its ready solubility in alcohol of 0.838 and by the fact that its volatile oil is acted on by potassium.

In South America pichurim seeds are said to be used as a substitute for nutmeg, and have even been called by that name. They are rare in this country. The oil obtained from the tree is said to impart its odor to the perspiration and urine, and to be useful in *rheumatism, gout*, etc.

Picoline. *Alphamethylpyridine. Alphapicoline.* $C_5H_4.N(CH_3)$.—This is obtained by the dry distillation of bones or coal. It is a colorless liquid having a specific gravity of 0.952, and is miscible with both water and alcohol. It has been used as a nerve sedative and to lessen heart action when diseased.

Picrasma. *Picrasma quassioides* (Ham.) Benn. (Fam. *Simarubaceæ.*)—The wood of this upright shrub or small tree, which grows in the subtropical Himalayas, and resembles closely the *Ailanthus* in its appearance, has an intensely bitter taste, and has been proposed as a substitute for quassia. W. Dymok and C. J. H. Warden have found in it a crystalline principle which they believe to be quassin, and to exist in the probable proportion of from 0.02 to 0.03 per cent. The same investigators believe that the drug has in it a peculiar alkaloid. (*P. J.*, xx, 1889.) A principle analogous to quassin was isolated by Shimoyamo from the bark of *P. eilantoides.* (*Ap. Ztg.*, 1892, 439.)

Picrotoxin.—This is a feebly acid principle found in the *Cocculus Indicus* (see Part I). It was formerly official in both the U. S. P. 1890 and the British Pharmacopœia, 1898. It occurs as: "Colorless, flexible, shining, prismatic crystals, or a micro-crystalline powder, odorless, and having a very bitter taste; permanent in the air. Soluble, at 15° C., in 240 parts of water, and in 9 parts of alcohol; in 25 parts of boiling water, and in 3 parts of boiling alcohol; also soluble in solutions of the alkalies, and in acids. Very slightly soluble in ether or chloroform. Picrotoxin is neutral to litmus paper. When heated to 200° C., picrotoxin melts, forming a yellow liquid, and upon ignition it is consumed, leaving no residue. Concentrated sulphuric acid dissolves Picrotoxin with a golden-yellow color, very gradually changing to reddish-brown, and showing a brown fluorescence. On mixing about 0.2 Gm. of powdered sodium nitrate with 3 or 4 drops of sulphuric acid, in a small, flat-bottomed capsule, sprinkling a minute quantity of Picrotoxin over it, and then adding, from a pipette, concentrated solution (1 in 4) of sodium hydrate, drop by drop, until it is in excess, the particles of Picrotoxin will acquire a brick-red to deep red color which fades after some hours. On diluting 2 cc. of alkaline cupric tartrate volumetric solution with 10 cc. of water, and adding a small portion of Picrotoxin, red cuprous oxide will be separated within half an hour at ordinary temperatures, and much more rapidly upon the application of heat. The aqueous solution of Picrotoxin should remain unaffected by mercuric or platinic chloride test-solution, tannic acid test-solution, mercuric potassium iodide test-solution, or other reagents for alkaloids (absence of *alkaloids*)." *U. S.*, 1890. It may be separated from acidulated aqueous solution, but not from alkaline, by shaking out with chloroform.

By the action of hydrochloric acid it is deposed into two dilactones called *picrotin*, $C_{15}H_{18}O_7$, and *picrotoxinin*, $C_{15}H_{16}O_6$. Picrotoxinin shows a brick-red color, when tested with the Langley reaction, while picrotin is indifferent in this case. See a paper by Meyer and Bruger, *Ap. Ztg.*, 1890, 67. In Europe, picrotoxin was at one time added to malt liquors in order to give them bitterness, and intoxicating properties,—but the practice is forbidden by law, in England, under heavy penalties and is rarely, if ever, practised now. For method of detection see *U. S. D.*, 20th edition, p. 1550. To procure picrotoxin, the aqueous extract of the seeds is triturated with pure magnesia, and then treated with hot alcohol, which dissolves the picrotoxin, and yields it upon evaporation. In this state, however, it is impure. To obtain it colorless it must be again dissolved in alcohol, and treated with animal charcoal. After filtration and due evaporation, it is deposited in the crystalline form.

Picrotoxin is a violent poison to all classes of vertebrates, producing, when in sufficient dose, violent convulsive attacks with periodic arrest of respiration, slowing of the heart beat, and finally death. In mammals the pupils are usually contracted although later dilated, there is salivation, frequently vomiting, and stupor deepening into coma. The precise mechanism of the convulsive attacks is not known but there appears to be an intense stimulation of the whole central nervous system, including the cerebrum, medulla and spinal cord. In frogs the convulsions persist after removal of the cerebrum but are abolished by destruction of the medulla; in mammals they are modified by removal of the cerebrum and disappear when the pons is destroyed. Koppen (*A. E. P. P.*, 1892, xxix) has shown that in mammals picrotoxin antagonizes the somnifacient effects of chloral hydrate and according to Kossa (*Ungar. Arch. f. Med.*, 1892, i) it increases the toxicity of morphine. The exciting effect upon the medullary centers is shown by the rise in blood pressure due to an action upon the vasomotor center, by the slowing of the pulse from stimulation of the cardio-inhibitory center, by the rapid respirations, and by the emesis. There is salivation, contraction of the pupil, and sweating, also due to an action upon the nerve centers. According to Hayashi (*A. E. P. P.*, 1903, l, p. 247) the drug has a marked antipyretic effect even in doses too small to cause convulsions. Tatum (*J. P. Ex. T.*, 1922, xx, 385) finds that small doses increase the amount of sugar in the blood. In man picrotoxin acts as it does in the lower animals and a number of cases of serious and even fatal poisoning have been produced by it or the plants in which it is found.

Picrotoxin has been used in various nervous diseases such as *epilepsy, hystero-epilepsy* and *chorea.* It has also been used in the treatment of *night sweats;* such effect as it may have in this condition is due to its stimulant action upon the circulation and respiration. Paterson (*S. M.*, 1907) recommends it for the prevention of post-anesthetic *vomiting. Dose,* from one-hundredth to one-thirtieth of a grain (0.0006 to 0.002 Gm.).

Pidan.—This name is applied to a Chinese egg food which is a product of bacterial change brought about by long keeping. The changes that are produced are similar to those occurring in the ripening of cheese.

Pinckneya. *Pinckneya pubens* Michx. *Georgia Bark. Bitter Bark. Fever Tree.* (Fam. *Rubiaceæ.*)—A large shrub or small tree, native to South Carolina, Georgia, and Florida, in marshy banks of streams within the pine barrens. It bears ovate or oblong, opposite leaves and large showy cymes of white, tubular flowers, dotted with red. The bark is bitter and has been used with alleged advantage in *intermittent fever.* E. H. Naudain (*A. J. P.*, April, 1885) found in it a glucoside, *pinckneyin*, but no alkaloid.

Pineapple. *Ananas sativa* Schult. f. (Fam. *Bromeliaceæ.*)—This is an herb indigenous to tropical America and cultivated in Florida and other subtropical districts for its delicate fruit. The fruit consists of a dense spike of connate fleshy berries and bracts, forming together an ovoid or subglobular compound fruit, which is seedless through cultivation, and crowned by a tuft of rigid leaves. Some years ago V. Marcano discovered that the juice of the ordinary *pineapple* has the power of digesting proteid vegetable and animal substances. R. H. Chittenden (*Trans. Connecticut Academy*, vol. viii, 1891) found that the fresh pineapple juice is a constant and powerful digestant of albuminous matters; that the ferment is decidedly active in the presence of either acids or alkaline carbonates, but is most energetic in neutral solution; that it is most active between 50° and 60° C.; still digests at 30° C., but is destroyed at a temperature of 70° C.; the ferment, to which the name *bromelin* has been given, is more nearly related to trypsin than to pepsin, forming during its action not only proteoses and peptone, but also leucine and tyrosine.

E. V. Flack found in fresh pineapples grown in Cape Colony: Crude fat 1.11 per cent., proteins 0.49 per cent., crude fiber 0.33 per cent., nitrogen-free extract 13.51 per cent., ash 0.70 per cent., silica 0.069 per cent., lime 0.047 per cent., potash 0.358 per cent., phosphoric oxide 0.024 per cent., and moisture 83.86 per cent. (*Chem. News*, 1912, 99.)

Pimpinella. *N. F. IV. Pimpernel Root. Pimpinella Saxifraga* L. *Small Burnet Saxifrage. Saxifraga. Radix Pimpinellæ,* P. G. *Grand Boucage,* Fr. *Pimpinell, Bibernell,* G.—"The dried rhizome and roots of *Pimpinella Saxifraga* Linné, or *Pimpinella magna* Linné (Fam. *Umbelliferæ*)." *N. F. IV.*

Pimpinella Saxifraga L. is a smooth-stemmed perennial herb attaining a height of 1 to 2 ft. It bears pinnate leaves, the leaflets of which are ovate to sub-orbicular, serrate below and narrow-lobed above. Its flowers are white and arranged in compound umbels. *P. magna* L. resembles the former species but has all of its leaflets ovate-serrate, somewhat cut, the terminal one being 3-lobed. Both of these herbs are indigenous to Europe. They are also naturalized, growing along roadsides and in waste places in the northern United States and Canada. The root has a strong, aromatic, yet unpleasant odor, and a sweetish, pungent, biting, aromatic, bitterish taste. Pimpinella was described by the N. F. as "cylindrical or slightly tapering, from 10 to 20 cm. in length and from 1 to 1.5 cm. in diameter at the crown, frequently branching, sometimes split longitudinally or broken into pieces; the upper or rhizome portion annulate, with undeveloped stem buds and a few attached stem remains which should not be over 5 cm. in length; roots longitudinally wrinkled, slightly annulate, cortex thin, easily detached; fracture short when dry, tough and flexuous when damp; externally light yellowish-brown; internally porous; cortex broad and whitish with numerous groups of projecting radial bast fibers and reddish-brown oleoresin cells; wood yellowish, usually with a few indistinct fibers, medullary rays interrupted, cambium zone distinct. Odor aromatic; taste sweetish, pungent and acrid.

"The powdered drug, when examined under the microscope, shows numerous simple or two- to four-compound starch grains, the individual grains being from 0.004 to 0.01 mm. in diameter; secretion canals from 0.05 to 0.06 mm. in diameter; tracheæ reticulate or scalariform, from 0.035 to 0.07 mm. in breadth; fibers, thin-walled numerous, thick-walled with simple pores few (*P. magna*).

"Pimpinella yields not more than 5 per cent. of ash." *N. F. IV.*

The commercial supplies of this drug are imported from Germany.

Its active constituents are volatile oil and an acrid resin. The yellow volatile oil has an odor recalling parsley, and a biting taste. Buchheim obtained from the alcoholic extract a crystalline principle, which he called *pimpinellin*, $C_{13}H_{10}O_5$. It is insoluble in water and petroleum ether, but soluble in alcohol. It is considered diaphoretic, diuretic, and stomachic, and has been used in *chronic catarrh, asthma, dropsy, amenorrhea*, etc. The *dose* in substance is about half a drachm (2.0 Gm.), and in infusion two drachms (7.7 Gm.). The root is used also as a local stimulant in toothache, etc.

Pinguicula Vulgaris L. and **Pinguicula Alpina** L. (Fam. *Lentibuliariaceæ.*) *Butterwort.*—These carnivorous plants of the northern United States and Canada are used as a folk medicine in the treatment of wounds and as a purgative. It has been asserted that *P. vulgaris* contains a proteolytic ferment; this has been used in combination with the extract of thyme in the treatment of whooping-cough under the name of "*diatussin.*" The *dose* of diatussin for a child of five years is one to three drops twice a day.

Pini-Pini. *Arra Diabo.*—This is the bark of *Jatropha urens* L. (Fam. *Euphorbiaceæ*). This stinging, spiny Brazilian plant has been long used by the natives of Southern America as a blistering agent. Very little is known of its constituents.

Piper Novæ-Hollandiæ Miq. (Fam. *Piperaceæ.*)—The berries of this Australian pepper contain a volatile oil, and are said to be useful in *gonorrhea* and allied diseases.

From the leaves of *Piper ovatum* Vahl, a plant found growing in Trinidad, Dunstan and Carr (*Chem. News*, 1895, 278) extracted a crystalline principle, *piperovatine*, $C_{16}H_{21}NO_2$. It is insoluble in water, but soluble in alcohol. It is said to act as a depressant of both motor and sensory nerves, and as a stimulant to the spinal cord.

Piperazine. *Arthriticine. Diethylene-diamine. Piperazidine.* $N_2\left\{\begin{matrix}H_2 + 6H_2O\\(C_2H_4)_2\end{matrix}\right.$.—This is formed by the action of ammonia upon ethylene bromide or chloride. A mixture of bases from this reaction is fractionated, and from the fraction boiling between 130° and 180° C., the dietnylenediamine separates on cooling. It forms glassy lustrous tables, melting at from 104° to 107° C., and boils at 145° C. Piperazine is very soluble in water and slightly less so in alcohol. Exposure to air is said to cause its eventual decomposition, due to the fact that it absorbs carbon dioxide from the air. It is strongly alkaline and combines with acids to form salts, and is incompatible with alkaloids; almost all oxidizing agents decompose it. Iron salts or compounds precipitate it from solution and when triturated dry with acetanilid, phenacetin or antipyrine it forms a liquid compound. In experiments made by Bock upon rabbits, no evidence of stimulating properties could be obtained. The blood pressure was never increased, but if the dose were large enough was temporarily depressed. In a cold aqueous solution it is said to dissolve twelve times as much uric acid as will lithium carbonate, and one part of uric acid and piperazine dissolves in fifty parts of water, while lithium urate requires three hundred and sixty-eight times its own weight to dissolve it.

Piperazine was introduced into medicine because its power of dissolving uric acid in the test tube led to the hope that it would exercise a similar solvent action in the system, and prove a valuable remedy, not only in the treatment of uric acid *gravel* and *calculi*, but also in *gout*. While piperazine enjoyed for a time a wide popularity in the treatment of *gout*, the present evidence is that it is of little if any value. Hanzlik (*J. Lab. Clin. M.*, Feb., 1917, 308) has found that in quantities corresponding to the therapeutic dose it does not increase the solvent action of the urine upon uric acid. Umpfenbach's statement that it is a powerful diuretic is denied by Hanzlik. During the taking of piperazine the urine usually is reddish-brown, and the drug can be readily obtained from the urine. Piperazine may be given hypodermically in a 2 per cent. solution, which is said to produce some pain but no abscesses; or, better, fifteen grains (1.0 Gm.) of it may be administered during the day in a quart of plain or carbonated water. It is so hygroscopic that it cannot well be given in pill or powder.

Under the name of *ichthyolidin* the ichthyolate of piperazine has been proposed as a more effective method of administering this drug.

Piperazine Quinate. *Sidonal.*—This is introduced with the idea of combining the powers of quinic acid, which hastens uric acid elimination, with the solvent properties of piperazine. It is a white crystalline powder with a faintly acid reaction, readily soluble in water. It is used in *gout* and in *neurasthenia* in *doses* of from ten to twenty grains (0.65–1.3 Gm.), but is of very doubtful service.

Piperonal. *Heliotropin.*—This interesting substance, although used almost exclusively in perfumery, has been recommended by Fraggani (*Ph. Centralh.*, xxviii, 253) as an antiseptic and antipyretic and by Moore (*J. A. M. A.*, 1918, lxxi) as a protective against lice. It may be obtained by the oxidation of piperic acid. This piperonal is the aldehyde of *piperonylic acid*, $C_6H_3(COOH)\genfrac{}{}{0pt}{}{O}{O}>CH_2$, which, as the formula indicates, is the methylene ester of protocatechuic acid, $C_6H_3CO\text{-}OH(OH)_2$. See also *Schim. Rep.*, 1903, 133.

Pipi Root.—The root of the *Petiveria alliacea* L. (Fam. *Phytolaccaceæ*). The root of this shrub, which grows in Mexico, attracted some notice in the latter part of the 19th century as a stimulating expectorant and diaphoretic. For further description see *U. S. D.*, 20th ed., p. 1554.

Piscidia. *Piscidia Erythrina* L. *Jamaica Dogwood. Fish-Poison Tree. Écorce du Bois de chién. Écorce de Piscidie. Mulungu. Murungu.*—This is a leguminous tree growing throughout the West Indies and the neighboring countries, being found in Florida, Texas, Mexico, and the northern portion of South America, and yielding to commerce a very valuable wood. It is characterized by having imparipinnate leaves with 7–11 oblong or elliptical leaflets, purplish-white flowers and legumes with 6–8 black seeds. From time immemorial the bark has been used for catching fish. The leaves, twigs, and root bark are collected, macerated with the residue from the distillation of rum or with lime water, then transferred into baskets, and the latter dragged up and down the water until the fish are stupefied.

The bark is in pieces of 5–10 cm. in length and about 8 cm. in width, having a thickness of 1.5 cm. The outer surface varies from a yellowish to a dark brown and is frequently studded with flattened protuberances of a lighter color than the surrounding cork. The central part of the bark is much lighter colored, and, when wet or freshly broken, is of a peculiar blue-green color. The bark has a strong odor resembling opium. It is acrimonious, and produces a burning sensation in the mouth and pharynx.

E. Hart obtained a neutral principle, $C_{29}H_{24}O_8$, to which he gave the name *piscidin.* (*A. J. P.*, 1883, 369.) Berberich (*A. J. P.*, Sept., 1898) showed that the principle was glucosidal and found their melting point to be 192° C. Paul C. Freer and A. M. Clover (*A. Pharm.*, Feb., 1901) found this principle to consist of two distinct chemical compounds. The first of these forms colorless, highly refracting rectangular prisms, melting at 201° C.; composition $C_{23}H_{20}O_7$. The second separates from alcohol in fine yellow needles, melting at 216° C.; composition $C_{22}H_{18}O_6$. The authors found also in the aqueous extract of the bark *piscidic acid* soluble in water; insoluble in chloroform, benzene or ligroin. It forms acicular crystals, which melt at 182° to 185° C.; composition $H_2.C_{11}H_{10}O_7$.

Ott (*T. G.*, March, 1883) has shown that the Jamaica dog wood has narcotic properties and that it causes dilatation of the pupil, increases secretion of sweat and rise of blood pressure. Pittenger and Ewe (*A. J. P.*, 1919, p. 580) find that it affects dogs very similarly to cannabis but requires approximately 17 times the dose of the latter drug.

The exact practical value of the drug has not been determined, nor are the results produced in man, by doses approaching toxic, known. Hamilton took a drachm, when suffering with severe toothache, on going to bed. He first felt a violent sensation of heat internally, which gradually extended to the surface, and was followed by profuse perspiration, with profound sleep for twelve hours. On awaking, he was quite free from pain, and without the unpleasant sensations which follow a dose of opium. Various practitioners have reported good results from its use as an anodyne in *neuralgia, nervous insomnia, whooping cough*, etc., but in other hands it has failed to do good. H. C. Wood found it in one case of neuralgia to produce great nausea and gastric distress without evincing the slightest narcotic effect. (For formula for fluidextract by Lemberger, see *U. S. D.*, 19th ed., 1616.) The *dose* of the fluidextract is a fluidrachm (3.75 cc.), to be carefully increased.

Pithecolobium. *Pithecolobium Saman* Benth. (Fam. *Leguminosæ.*)—A shade-tree, growing from Mexico to Brazil, and planted for shade in Japanese coffee plantations, which yields a poisonous alkaloid, *pithecolobine-saponin*, whose physiological action is analogous to that of sapotoxin.

Plantain. *Plantago major* L. *Rib Grass. Ribwort. Ripple Grass. Plantain*, Fr. *Wegerich*, G. (Fam. *Plantaginaceæ*).—The leaves are saline, bitterish, and acrid to the taste; the root is saline and sweetish. The common plantain weed was formerly considered refrigerant, diuretic, deobstruent, and somewhat astringent. The ancients esteemed it highly, but it is at present never used, except externally in domestic practice as a stimulant application to sores. The leaves are applied whole or bruised in the form of a poultice. *Plantago media* L., or *hoary plantain*, and *P. lanceolata* L., or *rib grass*, which are also naturalized in America, possess properties similar to those of *P. major*, and may be used for the same purposes.

For results of examination of the leaves of *P. major*, see Rosenbaum (*A. J. P.*, 1886, 418.) J. F. Strawinski found in the rhizome a substance which he believes to be either phlobaphene or protocatechuic acid. (*A. J. P.*, 1898, 189.)

Bourdier (*A. Pharm.*, ccxlvi) has found in a number of species of *plantago*, including the *P. major*, a glucoside *aucubin*, which was isolated from the *Aucuba japonica.*

Plasmon.—The freshly precipitated casein of skimmed milk, after mixing with a slight amount of sodium bicarbonate, is kneaded and dried at a temperature of 70° C., in an atmosphere of carbonic acid gas. It contains a large amount of proteids and is asserted to be a highly nutritious and palatable food for convalescents and invalids.

Platinum. Pt. 195.2. *Platine, Orblanc*, Fr. *Platin*, G.—A silvery white metal of the group also including gold and iridium. Sp. gr. 21.5, melting point 1750° C. It is unaffected by alkalies and also by acids excepting nitro-hydrochloric. Halogens readily combine with it. The richest deposits of platinum are found in Russia although small amounts are mined in the United States of Colombia, in New South Wales, Australia, in the Ronda Mountains of Spain and in parts of Germany. *Platinum* and its salts are of much importance for various chemical manipulations. On account of its resistant properties platinum is used for dishes, crucibles and other apparatus used in analytical and manufacturing chemistry. Because of the high cost of platinum, substitutes which can be used in its place for laboratory apparatus, are constantly being sought. Among these are alloys of gold and platinum. Crucibles of this type are not suitable for electrolytic work nor for temperatures above 1000° C., but may be used for estimating $CaCO_3$,$BaSO_4$,Fe_2O_3, or ZnO. Such an alloy containing 89 parts of gold and 11 of platinum is known as *platino*. *Stellite* is an alloy of cobalt and iridium; *platinite* of chromium and steel. Alloys of palladium and gold have been proposed under the names of *palau* and *rhotanium*. *Illium* is an alloy of secret composition intended for the same purpose.

The *platinum sponge* is an active catalyzing agent, and is used for various oxidation processes. *Colloidal platinum*, formed by the action of an electric arc between platinum wires under water forms in water a deep black liquid, which has a strong catalytic effect, resembling in many respects the action of organic ferments. Under the name of *platinum chloride* there is used to a wide extent as a precipitant for alkaloids, and for various other chemical purposes, *chloroplatinic acid*, $H_2PtCl_6.6H_2O$. This is made by dissolving the metal in nitro-hydrochloric acid, and evaporating with hydrochloric acid until all the nitric acid is removed. *Platinum tetrachloride*, $PtCl_4.5H_2O$, may be obtained by mixing an aqueous solution of chloroplatinic acid with a solution of silver nitrate; a precipitate containing the silver, combined with some platinum and chlorine, separates, and the yellowish-red solution yields on evaporation fine, large, red crystals of platinum chloride. Under the name of *bichloride of platinum*, the double *chloride of platinum and sodium* was formerly used in medicine to a small extent in the treatment of *syphilis*, but has been abandoned. When injected into the circulation in *doses* of fifteen to thirty grains, the soluble salts of platinum cause in the lower animals a primary stage of motor excitement, followed by paralysis of the central nervous system and later of the muscles themselves. The *dose* of platinum and sodium chloride is from one-half to two grains (0.032–0.13 Gm.) two or three times a day, generally in pill form.

Plevacol.—This is a mixture of tri-cresol, formalin and *amido-benzoyl-eugenol*, which is employed in dentistry for the purpose of filling roots and capping amputated pulp. It forms yellowish-white, or colorless crystals, melting at 155° to 156° C., soluble in acetone, benzol, alcohol, and in glacial acetic acid on warming.

Plumbago Europea L. *Leadwort. Dentellaria.* (Fam. *Plumbaginaceæ.*)—A perennial, herbaceous plant, growing in the south of Europe. It has an acrid taste, and, when chewed, excites a flow of saliva. This is particularly the case with the root, which has been long used to relieve toothache; hence its French name *dentelaire*. A decoction of the root in olive oil has been highly recommended for *itch*. A crystallizable, acrid principle, called *plumbagin*, has been extracted from the root by Dulong. (*J. P. C.*, (2), xiv, 441.) *Plumbago zeylanica* is said to be a very powerful diaphoretic.

Plumiera. *Pagoda Tree.*—The bark of *Plumiera sucuuba* Spruce (Fam. *Apocynaceæ*), a plant growing in South America which the natives of Brazil have long used in the treatment of fevers. It is asserted also to be an anthelmintic and emmenagogue. Plumier, the French botanist, first brought this plant to the attention of the medical profession. The important constituents of the plant are *plumierin* (*agoniadin*), $C_{21}H_{26}O_{12} + H_2O$, and *plumieric acid*, $C_{20}H_{24}O_{12}$. The *P. acutifolia*, said to contain an alkaloid, $C_{57}H_{72}N_{33}$, has been used in the treatment of *gonorrhea*.

Poison Gas.—Duringthe World War a number of poisonous gases were employed by various methods. The methods employed may be divided into two groups, those in which large cylinders of the gas were opened in a favorable wind and allowed to drift towards the enemy and those in which various containers, either artillery shells or hand grenades, were exploded in the neighborhood of the enemy. Norris (*J. A. M. A.*, 1918, lxxi, p. 1822) divided the gases into five groups as follows: 1. Lacrimators. These include the bromo-acetone, $CH_2BrCOCH_3$, xylene, bromide and benzyl bromide, $C_6H_5CH_2Br$. Their action is to cause intense irritation in the eye with lachrymation and temporary functional blindness. 2. Sternutators. These, of which *diphenylchlorarsin*, $(C_6H_5)_2AsCl$, is the most important example, irritated the mucous membrane of the upper respiratory tract causing sneezing, and coughing often with headache and vomiting. Their action is very rapid and they were employed chiefly as a preliminary to bombardment with more fatal gases in order to prevent the putting on of protective gas masks. 3. Lung irritants, including chlorine, *phosgen* (*carbonylchloride*, $COCl_2$) *diphosgen* (trimethylchloraforminate), and oxychlorcarbon. These gases cause intense irritation of the respiratory tract resulting in pulmonary edema. 4. Vesicants, of which the best known are the so-called *mustard gas* (*dichlorethylsulphide*) $(CH_2ClCH_2)S$ and *dichlormethylether* $(CH_2Cl)_2O$. These caused, when in contact with the skin, blistering, followed by ulceration and if inhaled intense irritation of the larynx, trachea and bronchii. In the latter cases death was due to broncho-pneumonia. 5. Blood-poisons. Carbon monoxide, which caused asphyctic death by combining with hemoglobin, and arsin which caused hemolysis.

The most deadly of these cases were lung irritant groups. The earliest used was chlorine gas which was afterwards replaced by phosgen (also known as *palite*), which in turn was later replaced by the *diphosgen* or *superpalite*. The latter is so intense an irritant that, in sufficient concentration, when inhaled may kill by laryngeal spasm. In the more common groups of cases from the inhalation of less concentrated vapors, death was due to asphyxiation caused by pulmonary edema. Vapors as dilute as one part in one million are toxic if breathed over a considerable period of time. Cow (*L. L.*, May 29, 1915) recommends the use of atropine combined with inhalations of oxygen in the treatment of chlorine-gas poisoning. Diphosgen in contact with water forms hydrochloric acid. The fatal cases from this gas usually died within 24 hours. The treatment consists of absolute rest, body warmth, venesection, cardiac stimulation and inhalation of oxygen. All opiates and anodynes are contraindicated. Expectorants and depressants are also to be avoided.

Mustard gas, also known as *yperite*, has a faint odor similar to that of French mustard and is not immediately irritant so that soldiers often remained in contact with the gas for several hours before becoming conscious of its presence. The symptoms usually appeared in from 1 to 3 hours. The early symptoms were smarting and redness of the eyes which was followed by photophobia and lachrymation. Later there is widespread purulent irritation, in all the upper respiratory tracts. These cases generally also showed destructive irritation of the skin as clothing saturated with the gas is irritant enough to destroy the epidermis.

According to Marshall (*J. A. M. A.*, 1919, lxxiii, 684) the so-called mustard gas is really not a gas but an oily liquid which vaporizes slowly in the air. Animals exposed to an atmosphere containing one part per million die after 8 hours' exposure. There may be an absorption of the gas through the lungs in which case systemic poisoning may be caused. This, however, is not common in conditions of actual warfare. The symptoms following the systemic ingestion of this gas are salivation, hyper-excitability and convulsion, vomiting and diarrhea and slow irregular heart. He says that negroes are much more resistant to the gas, at least as far as the skin lesions are concerned, than white men.

For studies of the pathology of mustard gas poisoning see Marshall, Lynch and Smith (*J. P. Ex. T.*, 1918, xii, 265).

The treatment of mustard gas poisoning should consist of thorough cleansing of the entire body with soap and water, douching of the eyes, nose and mouth with a 1 per cent. solution of sodium bicarbonate, followed by installation of a bland oil containing ½ per cent. of dichloramin-T, which acts not only as an antiseptic but as a chemical antidote by virtue of its chlorine content. Skin burns should be treated with alkaline dusting powders.

Pollantin (Fall). *Dunbar's Serum.*—A hay fever serum prepared by introducing the pollen of golden rod and other plants into the blood of animals. After a certain period of time, blood is drawn and from this the serum is prepared. While the claims made for this product by its manufacturers are no doubt exaggerated, yet clinical evidence has proven it to be of value in some cases. It is used by installation in the eye and nostrils, and not intended for hypodermic use. This serum may also be obtained in powder form, which is merely the evaporated serum powdered and diluted with milk sugar.

Polygala. *Polygala polygama* Walt. (*P. rubella* Muhl.) (Fam. *Polygalaceæ.*) *Bitter Milkwort. American Bitter Polygala. Polygale, Laitier*, Fr. *Kreutzblume, Milchwurz*, G.—*Bitter polygala* is a perennial herb, up to 1 foot in height which grows from Nova Scotia to Florida and Texas. It bears numerous cleistogamous flowers. It was formerly official. It has a strong and permanent bitter taste, which it yields to water and alcohol. In small doses bitter polygala is tonic, in larger, laxative and diaphoretic. It appears to be closely analogous in medicinal virtues to *Polygala amara* L., of Europe, which is used for a similar purpose. From the seeds of the *P. butyracea* Heck. and Schlag., an African plant, the natives prepare an edible fat. (See *P. J.*, 1889, xx.)

A senega which was first used in Japan, and which has been referred by some writers to *P. japonica*, by others to *P. tenuifolia*, has been examined by Reuter, who finds in it 0.8 per cent. of resin, traces of methyl salicylate, and 8.8 per cent. of an oil which has somewhat the odor of patchouli.

Polygonatum. *Polygonatum officinale* (L.) All. (*Convallaria Polygonatum* L., *Polygonatum uniflorum* Gilib.) *Sealwort. Solomon's Seal. Sceau de Salomon, Genouillet*, Fr. *Weisswurzel, Salomons Siegel*, G. (Fam. *Liliaceæ.*)—A perennial, herbaceous European plant, whose root is inodorous. It is said to be emetic. In former times it was used externally in *bruises*, especially those about the eyes, in *tumors, wounds*, and *cutaneous eruptions* and was highly esteemed as a cosmetic. At present it is not employed. The berries and flowers are said to be acrid and poisonous. *Polygonatum multiflorum* L. (All.) (*C. multiflora* L.), which grows in Europe and Asia, is analogous to the preceding in properties.

Polymnia. *Polymnia uvedalia* L. *Leafcup. Bear's Foot.* (Fam. *Compositæ.*)—A tall, rough-hairy, shrubby plant, growing in rich soil from New York to Missouri and southward. Great virtues as a remedy in *malarial splenic enlargements* have been attributed to this plant.

Polypodium. *Polypody. Fern Root.*—Various species of this genus of ferns are asserted to have medicinal properties. *Polypodium vulgare* L., very common both in Europe and America, was believed by the ancients to be an active cholagogue purgative, and has been used in modern times as an expectorant in chronic *catarrh* and *asthma. Dose*, from one to eight drachms (3.9–31 Gm.), usually given with a cathartic. The rhizome, as it usually occurs in commerce, is from 2 to 12 cm. in length and 3 to 8 mm. in thickness, somewhat contorted, covered with brown, easily separable scales, which should be removed before being used. Its color is reddish-brown, with a tinge of yellow, its odor disagreeably oleaginous, its taste peculiar, sweetish, somewhat bitter, and nauseous. *P. adiantiforme*, of Porto Rico, is believed by the natives to be a powerful antisyphilitic. It must be used freely for several months in the advanced stages of the disease. *P. friederichsthalianum*, of Central America, has had similar properties attributed to it.

Polytrichum. *Polytrichum juniperinum* Hedw. (Fam. *Polytrichaceæ.*) *Herba Adianti Aurei. Rock-brake Herb. Female Fern Herb. Perce Mousse. Frauenhaar. Jung Fernhaar. Widertot. Wolfgerste. Hair Cap Moss. Robin's Rye. Golden Maidenhair.*—This indigenous moss was esteemed by some physicians of the past generation to be actively diuretic and therefore useful in *dropsy*.

Pongamia. *Pongamia pinnata* W. F. Wight. (Fam. *Leguminosæ.*)—*Pongamia* or *kurung oil* is expressed from the seeds of an East Indian tree. It is deep yellow to reddish-brown, fluid at 15.6° C., but below that it is solid with sp. gr. of 0.9352 (*P. J.*, 72, p. 492). It is especially commended in *pityriasis versicolor* and other parasitic skin diseases. (*P. J.*, Feb., 1883.)

Poppy Capsules. *N. F. IV. Papaveris Fructus. Papaveris Capsulæ.* Br. 1898. *Papaver*, U. S., 1870; *Capsules de Parot blanc ou Pavot officinal*, Fr. Cod.; *Fructus Papaveris immaturi*, P. G.; *Unreife Mohnköpfe, Kapseln des Weissen Mohns, Mohnkapseln, mohnköpfe*, G.; *Papavero*, It.; *Cabezas de amapola*, Sp.—"The dried, fully grown, unripe fruit of *Papaver somniferum* Linné (Fam. *Papaveraceæ*). Separate and reject the seeds before using the fruit in pharmaceutical preparations." *N. F.*

Poppy capsules were formerly official in the Br. (1898) and in the N. F. (IV.) but have been dismissed from both. In England the poppy has been largely cultivated for its capsules, which are gathered as they ripen, and taken to market enclosed in bags. The N. F. directs them to be collected before they are quite ripe, as they then contain more of the active milky juice. When ready for collecting they are a yellowish-green color. They are employed chiefly in preparing Syrup of Poppy Capsules.

Dried *poppy capsules* vary in size from the dimensions of a small egg to those of the fist. They differ also in shape according to the variety of the poppy from which they are procured. On the Continent two sub-varieties of the white poppy are recognized, the *long*, and the *round* or *depressed*. Of these, according to Aubegier, the long are richest in morphine, and his conclusions are confirmed by Meurein, who also found the largest capsules most efficient. Those commonly found in commerce are spheroidal, flattened below, and surmounted by a crown-like expansion —the persistent stigma—which is marked by numerous diverging rays that rise somewhat above the upper surface and appear to be prolongations of partial septa, or partitions, proceeding along the interior circumference of the capsule from the top to the bottom. In the recent state, the seeds, which are very numerous, adhere to these septa, but in the dried capsule they are loose in its cavity, and the N. F. directed that they should be separated before the capsule is used. They were described in the N. F. as "globular or ovoid, usually from 3 to 3.5 cm. in diameter, but varying in size, more or less sunken or depressed on the sides, contracted at the base into a sort of neck immediately above a tumid ring at the point of attachment with the stalk; crowned at the summit with the seven- to fifteen-rayed stigma disk; outer wall of pericarp smooth, hard, grayish-yellow to brownish-yellow, often marked with black spots; interior surface rugose, finely striated transversely, and bearing thin, brittle, membranous placentæ which extend from the sutures toward the center, and bear on their faces and edges numerous, minute, conspicuously reticulated, reniform white seeds. Odorless; taste slightly bitter.

"The powdered drug is grayish-yellow, and, when examined under the microscope, exhibits fragments of the epicarp composed of thick-walled polygonal cells, the cells of the outer layer non-porous, up to 0.05 mm. in diameter and with occasional stomata, the latter up to 0.035 mm. in length; the cells of the inner layer of the epicarp often with numerous simple pores; portions of the soft, spongy sarcocarp consisting of isodiametric or irregular parenchyma and branching milk ducts, the latter up to 0.06 mm. in width, of variable length and with thin, non-porous walls; fragments of the inner wall of the pericarp and the outer wall of the placental tissue composed of polygonal or somewhat elongated cells with porous walls, up to 0.06 mm. in width and up to 0.3 mm. in length, the walls of the latter cells often slightly lignified; spiral and annular tracheæ up to 0.035 mm. in width and reticulate tracheæ up to 0.06 mm. in width; sclerenchyma cells few with simple or oblique pores; starch grains few, small, somewhat rounded; fragments of the reticulately pitted seed-coat very few or absent. Poppy Capsules yield not more than 10 per cent. of ash." *N. F. IV.*

Poppy capsules contain the same active ingredients as opium but in smaller proportion. They were used chiefly in the form of a syrup as a mild narcotic. The *dose* is from ten to twenty grains (0.65–1.3 Gm.).

Portulaca. *Portulaca oleracea* L. *Garden* or *Common Purslane.* (Fam. *Portulacaceæ.*)—This is a fleshy, prostrate annual indigenous to Europe but naturalized in the United States and found frequently both on cultivated and waste grounds. It has been considered a cooling diuretic, and recommended in *scurvy* and urinary affections. The seeds have been considered anthelmintic, but are inert.

Potassio-Mercuric Iodide. *N. N. R.* 1924. *Potassii et Hydrargyri Iodidum. Mercuric Potassium Iodide. Mercury and Potassium Iodide. Potassium Iodohydrargyrate. Mayer's Reagent.* K_2HgI_4.—Mercuric iodide unites with the iodides to form a series of double salts known as *Iodohydrargyrates.* The potassium salt in the anhydrous state represents approximately 25.5 per cent. of mercury but it also crystallizes with either 1, 2 or 3 molecules of water. The anhydrous form occurs in commerce in yellow crystalline pieces, deliquescent in moist air. When mixed with its weight of water it forms a clear solution results, but on dilution mercuric iodide is slowly precipitated, unless an excess of potassium iodide be added; when dissolved in water containing sufficient potassium iodide it forms the compound $HgI_2 2KI$. Under the name of *Mercuric potassium iodide test solution* this liquid is official in the U. S. P. (See Part III.) Clayton suggests the practical method of simply evaporating *Nessler's solution* and collecting the crystals. (*Chem. News,* 1894, 102.)

This is an active preparation, which may be given in the same dose and for the same purposes as corrosive sublimate. It is formed when its components are prescribed together extemporaneously. It is not decomposed by the compound syrup of sarsaparilla, which is frequently used as a vehicle for it. Potassio-mercuric iodide was suggested by F. L. Winckler as a qualitative test of the organic alkaloids. F. F. Mayer subsequently employed, for volumetric analysis, a solution made with 13.546 grammes of corrosive sublimate, 49.8 grammes of potassium iodide, and a liter of distilled water. (See *Mercuric Potassium Iodide Test Solution, U. S. D.,* Part III.)

Potassio-mercuric iodide is a powerful germicide, rivaling mercuric chloride in its potency, and frequently used as a succedaneum for that salt. It has the advantage of not being precipitated by albumin. Its solutions are proven to undergo decomposition unless an excess of potassium iodide be present. Tablets containing the proper quantities of the potassium iodohydrargyrate and potassium iodide for making antiseptic solutions are now marketed by various manufacturing chemists.

Potassium Bisulphate. *Potassii Bisulphas. Acid Potassium Sulphate.* $KHSO_4 = 136.18$.—This is a by-product in various chemical operations, being left as residue when potassium salts are decomposed by sulphuric acid in excess. It is a white salt, the crystals having the form of right rhombic prisms so flattened as to be tabular. The salt has a bitter and extremely acid taste. It is soluble in twice its weight of cold and in less than its weight of boiling water. Alcohol does not dissolve it, but when added to an aqueous solution, precipitates the neutral sulphate. Exposed to the air, it effloresces slightly on the surface, and when moderately heated readily melts, and runs like oil. At a red heat it loses water and the excess of acid, and is reduced to a neutral sulphate. Owing to its excess of acid, it acts as an acid on the carbonates, causing them to effervesce. It is incompatible with alkalies, alkaline earths, and their carbonates, with many of the metals, and with most oxides. This salt was formerly called *sal enixum*. It is aperient. It answers, according to Barker, for preparing a cheap aperient effervescing draught. Equal weights—a drachm, for instance—of the bisulphate and of sodium carbonate may be dissolved separately, each in two fluidounces of water, then mixed, and taken in the state of effervescence. *Dose,* one or two drachms (3.9–7.7 Gm.).

Potassium Bromate. $KBrO_3 = 167.02$. *Potassii Bromas. Bromate de potase,* Fr. *Kaliumbromat, Bromsaures Kali,* G.—This salt is formed in the process employed for making the bromide and may be separated by crystallization. Colorless, cubical or tabular crystals, soluble in 15 parts of cold and 2 parts of hot water. Like potassium chlorate it oxidizes matter like sugar and sulphur and must be mixed with great caution with readily oxidizable substances. It is an ingredient in *Koppeschaar's solution,* which is employed in titrating phenol. (See *Tenth-normal Bromine Volumetric Solution,* Part III.)

Potassium Chloro-Platinite. *Potassium Platinochloride.* K_2PtCl_6.—Eight grains (0.5 Gm.) of this salt, which is used as a toning agent in photography, caused death in an infant of two months, preceded by violent gastro-enteritis and collapse. (*B. M. J.*, i, 1896.)

Potassium Cobalti-Nitrite. $CO_2(NO_2)_{12}K_6 + 2H_2O = 934.32$.—When potassium nitrite is added to a cobalt salt solution acidified with acetic acid, nitrogen is set free, and in course of time the double cobaltic and potassium nitrite separates as a yellowish crystalline powder, almost totally insoluble in acid solution. Wolcott Gibbs having suggested that this nitrite might be less fugacious than other nitrites, on account of its stability and relative insolubility, J. W. Roosevelt tried it in doses of from one-quarter to one-half grain (0.016–0.032 Gm.), every two hours, in kidney cases with high arterial tension and dyspnea, in *asthma,* and also in *cardiac valvular diseases.* He stated that the effects of the drug are similar to those of the nitrites, beginning in fifteen minutes and lasting from two to four hours.

Potassium Cyanide. *Potassii Cyanidum. U. S. VIII. Cyanide of Potassium. Potassii Cyanuretum. U. S.* 1850. *Cyanuret of Potassium. Kalium Cyanatum, Kaliumcyanid, Cyankalium,* G. *Cianuro potasico,* Sp. $KCN = 65.11$.—This salt is no longer official. It occurs in "white, opaque, amorphous pieces, or a white, granular powder, odorless when perfectly dry; deliquescent in the air and exhaling the odor of hydrocyanic acid. *Great caution should be used in tasting and handling this salt.* Soluble in about 2 parts of water at 25° C. Boiling water dissolves its own weight of the salt, but rapidly decomposes it. In alcohol it is but sparingly soluble. At a low red heat the salt fuses." *U. S. VIII.*

For processes of manufacture and tests of purity see *U. S. D.*, 19th edition, p. 996.

Besides the very extensive use of potassium cyanide and sodium cyanide in preparing electroplating solutions for gilding and silvering by electro-deposition, and in photography, large quantities are now consumed in the extraction of gold and silver from the fine residues or "tailings" where amalgamation fails to take up the precious metals. From such solutions of gold in potassium cyanide the metal is thrown out by the action of metallic zinc. Potassium cyanide has the power of dissolving silver oxide and may be used for the removal of silver nitrate stains from clothing. According to Guthrie a solution of three grains (0.2 Gm.) to the ounce (30 cc.), dropped in the eye every other day, will remove olive colored stains from the conjunctiva caused by silver nitrate. Owing to the large use of potassium cyanide for the recovery of gold, numerous accidental cases of poisoning occur in the reduction works. Potassium cyanide acts precisely like hydrocyanic acid as a poison. (See *Acidum Hydrocyanicum Dilutum.*) Five grains of it have repeatedly taken life. It is of no value as a medicine but was formerly employed occasionally as a substitute for hydrocyanic acid in *doses* of from one-eighth to one-quarter of a grain (0.008-0.015 Gm.).

Potassium Ferricyanide. *Ferricyanide of Potassium. Red Potassium Prussiate.* $K_3Fe(CN)_6$.—This is formed by passing a current of chlorine through a solution of potassium ferrocyanide, until the liquid ceases to form a precipitate with a solution of ferric chloride, a proof that the whole of the ferrocyanide has been converted into the ferricyanide. The solution, by due evaporation, yields the compound in question. It may also be prepared, in the dry way, by agitating finely powdered ferrocyanide with chlorine as long as it is absorbed. The reaction is explained by the following equation:

$$2K_4Fe(CN)_6 + Cl_2 = 2K_3Fe(CN)_6 + 2KCl$$

The radical ferricyanogen is supposed to be formed by the coalescence of two molecules of ferrocyanogen, and is sometimes represented by the symbol FCy. This salt, discovered by Gumelin, is in beautiful, deep, hyacinth red, anhydrous crystals, which are soluble in four parts of water. Its solution forms a delicate test for ferrous salts, with which it produces a blue precipitate; but with ferric salts it only produces a green or brown color. It is used in dyeing and calico printing. (See *Test Solutions,* Part III.)

Potassium Ferrocyanide. $K_4Fe(CN)_6 + 3H_2O = 422.35$. *Potassii Ferrocyanidum. U. S. VIII. Potassæ Prussias Flava. Ferrocyanide of Potassium. Yellow Prussiate of Potash. Ferroprussiate of Potash. Prussiate of Potash. Protocyanure jaune de Fer et de Potassium,* Fr. *Kalium Ferrocyanatum, Kalium Borussicum, Cyaneisenkalium, Ferrocyankalium, Gelbes Blutaugensalz,* G.—Potassium ferrocyanide was formerly prepared on the large scale by heating animal matters, such as dried blood, hoofs, chips of horn, woollen rags, old leather, the refuse of tallow chandlers called *greaves,* and other substances rich in nitrogen, with the pearlash of commerce and scrap iron.

In recent years almost all potassium ferrocyanide is prepared from the spent ferric oxide which is obtained in abundance during the purification of coal gas.

Potassium ferrocyanide is in "large, soft, transparent, yellow, four-sided, monoclinic, tabular crystals or prisms; odorless, and having a mild, saline taste. Slightly efflorescent on exposure to the air. Soluble in about 4 parts of water at 25° C., and in 2 parts of boiling water; insoluble in alcohol. When heated to 60° C., the salt begins to turn white from loss of water of crystallization, and when heated at 100° C., it is rendered anhydrous." *U. S. VIII.*

For further description and tests of purity see U. S. D., 20th ed., p. 1560.

Pure potassium ferrocyanide is almost non-toxic. Callies, as quoted by Pereira, found the commercial salt slightly poisonous, but the pure salt unproductive of harm innocuous.

This salt is manufactured on a large scale, chiefly for the use of dyers and calico printers. In chemical manufacturing it is employed to prepare diluted hydrocyanic acid, Prussian blue, and potassium and silver cyanides. Its only medicinal value is as an antidote in *copper sulphate poisoning*. *Dose,* five to ten grains (0.32–0.65 Gm.).

Potassium Glycerophosphate. *Potassii Glycerophosphas.* $K_2C_3H_5(OH)_2PO_4$.—The salt is very hygroscopic and has an alkaline reaction. This salt appears in commerce to-day as a colorless to yellowish liquid, miscible with water in all proportions, and containing from 50 to 75 per cent. of the salt. It is used for the same purposes as sodium glycerophosphate in *doses* of from three to six minims (0.2–0.4 cc.).

Potassium Iodate. *Potassii Iodas. Iodate de Potasse,* Fr. *Kaliumjodat, Jodsaures Kali,* G. KIO_3.—A white crystalline powder, very soluble in water. Demarquay and Custin assert that potassium iodate is superior to potassium chlorate as a local remedy in ulcerative and gangrenous *stomatitis, ptyalism, diphtheria,* and other diseases of the pharyngeal and buccal mucous membrane. *Dose,* from four to eight grains (0.26–0.5 Gm.).

Potassium Nitrite. *Potassii Nitris.—Nitrite of potassium* ($KNO_2 = 85.11$) is most readily obtained by fusing saltpeter with lead, which withdraws one atom of oxygen from the former, and forming thereby litharge. It is a white, fusible, and uncrystallizable mass, usually cast into sticks like the hydroxide. It is very deliquescent, and absorbs carbon dioxide from the air. It shares the activities of the nitrites, producing in animals their physiological effects, and being capable of replacing them in the treatment of disease. Its influence is comparatively slow and permanent. Five grains (0.32 Gm.) have produced mild poisoning. *Dose,* one to three grains (0.065–0.2 Gm.).

Potassium Percarbonate, $K_2C_2O_6 + H_2O$, is a colorless powder which slowly decomposes under the action of water, as follows:

$$K_2C_2O_6 + H_2O = 2KHCO_3 + O$$

In the presence of sulphuric acid, potassium percarbonate decomposes and forms hydrogen peroxide.

$$K_2C_2O_6 + 2H_2SO_4 = 2KHSO_4 + 2CO_2 + H_2O_2$$

This substance has not as yet been used in practical medicine, but is believed to be the material known as *antihypo,* much used in photography, and which has been recommended by Müller for the purposes of decolorizing and counterstaining tubercular bacilli. He washes the preparations for this purpose in 50 to 70 per cent. alcohol and places them for fifteen minutes in a 5 to 10 per cent. solution of potassium percarbonate, and after differentiating rinses in water and counterstains with methylene blue.

Potassium Perchlorate. *Potassii Perchloras. Hyperchlorate of Potassium.* $KClO_4 = 138.56$.—This salt is prepared by fusing potassium chlorate until it begins to assume a pasty condition. The cooled mass consists of potassium perchlorate and chloride. The absence of undecomposed chlorate may be known by a sample failing to communicate a yellow color to hydrochloric acid. The mass must be dissolved in the smallest possible quantity of boiling water, when perchlorate crystallizes out. It is sparingly soluble in water, and insoluble in alcohol. It is used in analytical chemistry as an oxidizing reagent and is formed in the estimation of potassium salts by the use of perchloric acid. Its effects are wholly different from those of potassium chlorate.

Potassium Persulphate. $K_2S_2O_8$. *Potassii Persulphas. Kaliumpersulfat,* G. *Anthion.*—Obtained by electrolyzing a solution of potassium bisulphate. It forms colorless crystals, soluble in about 50 parts of water. Used in photography, owing to its oxidizing of sodium thiosulphate to sulphate.

Potassium Phenolsulphonate. *Potassium Sulphocarbolate.* $C_6H_4(OH)SO_3K + H_2O$.—This forms white crystals soluble in water and alcohol, and melting at 400° C. Therapeutically it is very little used, but it has some use as an antiphylloxerin in checking the ravages of the grape vine parasite.

Potassium Phosphate. *Potassii Phosphas. Dibasic Potassium Phosphate,* $K_2HPO_4 = 174.25$.—The *potassium phosphate* which has come into use as a medicine is the *dipotassic orthophosphate,* having a composition precisely analogous to that of the medicinal sodium phosphate. It may be formed precisely as sodium phosphate is prepared; or by nearly saturating, by means of potassium carbonate, common or orthophosphoric acid, H_3PO_4. The medicinal potassium phosphate is a white, amorphous, deliquescent salt, crystallizing with difficulty. It has been given as an alterative in *scrofula* and *phthisis* with supposed advantage. The *dose* is from ten to thirty grains (0.65–2.0 Gm.), three times a day, dissolved in a teaspoonful of water.

Potassium Picrate. *Potassium Trinitrophenate. Potassii Picras. Kaliumpikrat, Pikrinsaures Kalium,* G. $C_6H_2(NO_2)_3OK$.—This salt may be made by neutralizing a hot solution of 20 parts of picric acid with 7 parts of potassium carbonate and crystallizing in a cool place. Small, yellow crystals, or a yellow powder of a bitter taste, soluble in 230 parts of cold water and 15 parts of hot water; nearly insoluble in alcohol. It must be handled with care, as it explodes by a blow or when heated.

Potassium Silicate. *Potassii Silicas.—Silicate of potassium,* also known as *soluble glass,* is prepared in the same way as the sodium salt. It varies commercially but is usually of the formula, $K_2Si_6O_7$. It may be used as a substitute for plaster of Paris in the preparation of rigid surgical dressings. The solution is applied of a syrupy consistence, by means of a brush, to the bandages, upon which it rapidly hardens, requiring only five or six hours for this result. The facility of removing the bandages by means of hot water is the advantage which *potassium silicate* possesses over most other dressings.

Potassium Sozoiodolate. *Potassium Diodoparaphenolsulphonate.* $C_6H_2I_2.OH.SO_3K$.—A colorless, inodorous, crystalline powder, soluble in 50 parts of water. It is used as a 10 per cent. dusting powder or ointment in the treatment of *herpes* and *eczema*, etc., and as a 25 per cent. ointment in *laryngitis, adenitis*, etc.

Potassium Sulphite. *U. S. VI. Potassii Sulphis. Kali Sulfurosum, Sulfis Kalicus. Schwefligsaures Kali*, G. $K_2SO_3.2H_2O = 194.30$.—Potassium sulphite is in "white, opaque, obliquely-rhombic, octahedral crystals, or a crystalline powder, somewhat deliquescent, odorless, having a bitter, saline, and sulphurous taste, and a neutral or feebly alkaline reaction. Soluble in 4 parts of water at 15° C. and in 5 parts of boiling water; only sparingly soluble in alcohol. When gently heated, the salt loses its water of crystallization (18.5 per cent.); at a red heat it is decomposed and leaves a residue of an alkaline reaction. The aqueous solution of the salt yields a white, crystalline precipitate on the addition of a saturated solution of bitartrate of sodium. Addition of diluted hydrochloric acid to the aqueous solution gives rise to the odor of burning sulphur, and the solution does not become cloudy (difference from *hyposulphite*)." *U. S. VI.* It decrepitates when heated. In the air it effloresces, absorbing oxygen, and being partially converted into the sulphate.

The medicinal uses of this salt are essentially those of the other sulphites. It acts as a slight laxative and diuretic. It escapes from the system with the urine, and may be found for some hours unchanged; at the end of twenty-four hours potassium sulphate is found in the urine instead of the sulphite, proving that the salt undergoes oxidation in the body. It is used for the same purposes as sodium sulphite, over which, however, it has no advantages. *Dose*, from fifteen grains to a drachm (1.0–3.9 Gm.).

Potassium Sulphocyanate. *Potassii Sulphocyanas. Potassium Thiocyanate. Potassium Rhodanide. Potassium Thiocyanide.* $KSCN = 97.18$. *Sulfocyanure de Potassium*, Fr. *Kalium Sulfocyanat, Rhodankalium*, G.—Potassium sulphocyanate, formerly called *potassium sulphocyanide*, is in long, striated, anhydrous prisms, deliquescent in a moist atmosphere, very soluble in alcohol, and having a cooling, somewhat biting taste. It was at one time suggested as a substitute for hydrocyanic acid but as far as we know is no longer used as a medicine. For method of making it see *U. S. D.*, 20th ed., p. 1563.

Potentilla.—*Cinquefoil. Potentilla reptans* L., the *creeping cinquefoil* of Europe, is naturalized from Massachusetts to Ohio, and *Potenilla canadensis* L., one of the common cinquefoils of America (Fam. *Rosaceæ*), have each been used as astringents in *diarrhea, chronic catarrhs, night sweats*, etc. According to J. C. Peacock (*A. J. P.*, 433, 1900), dried *P. norvegica* L. contains four, and *P. canadensis* thirteen, per cent. of tannic acid. (See *P. J.*, 1911, 350.)

Powder of Algaroth. *Pulvis Algarothi. Oxychloride of Antimony. Nitro-muriatic Oxide of Antimony.*—A powder rarely used now. For a description of its uses, properties, etc., see 14th edition, *U. S. D.*

Primula. *Primrose, Cowslip.*—The leaves of various species of primrose, especially the *Primula obconica*, produce in certain persons when handled an active dermatitis somewhat resembling that produced by the poison ivy. The toxic principle is contained in the glandular hairs. Its precise nature is unknown although Simpson (*J. A. M. A.*, 1917, lxix, 95) has presented evidence suggesting that it is of resinous character.

Primula obconica Hance (Fam. *Primulaceæ*) is a popular, perennial, winter-blooming house plant which has been introduced into the U. S. A. and Europe from China and now is commonly cultivated by florists. It is characterized by possessing a dense rosette of long-petioled, ovate-oblong or round-oblong leaves with irregularly scalloped-toothed margins and many long-stalked umbels of lilac or light purple flowers. Its leaves possess numerous glandular hairs, the heads of which contain an irritating principle.

From the roots of *Primula grandiflora*, Bongault and Alland have separated a crystalline polyatomic alcohol, *primulite*, which is said to be identical with the hepatomic alcohol, *volemite*. (*C. R. A. S.*, cxxxv, 796.) Two glucosides, *primeverin* and *primulaverin*, and an enzyme, *primverase*, were isolated by Goris and Mascnè. (*Chem. Cb.*, 1910, No. 3.) and later in the *P. officinalis* (*J. P. C.*, 1920, xxi, 284).

Prinos. *Black Alder. Winterberry. Feverbush. Prinos*, Fr., G.—The U. S. P. formerly recognized under this name the bark of *Ilex verticillata* (L.) A. Gray (*Prinos verticillatus* L.) (Fam. *Ilicaceæ*). This shrub, of which there are 3 well recognized varieties, grows in the United States from Canada to Florida and west to Missouri and Wisconsin, frequenting low, wet places. The berries, which have a bitter, sweetish, somewhat acrid taste, are sometimes used medicinally for the same purposes as the bark. The dried bark occurs in "thin, slender fragments, about 1 Mm. thick, fragile, outer surface brownish ash-colored, with whitish patches and blackish dots and lines, the corky layer easily separating from the green tissue; inner surface pale greenish or yellowish; fracture short, tangentially striate; nearly inodorous, bitter, slightly astringent." *U. S.*, 1880.

Black alder has been considered tonic and astringent, and has been used in *diarrhea* and as a substitue for Peruvian bark, but has no antiperiodic properties. In cases of flabby or ill-conditioned *ulcers* it is popularly used both locally and internally in decoction (two ounces in three pints of water boiled to a quart); *dose*, from two to three fluidounces (60–90 cc.).

Prioria. *Prioria Copaifera* Griseb. (Fam. *Leguminosæ.*)—The *oil tree* is a native of the West Indies. The seeds are edible and in Panama are sold under the names of *Cativa* or *Amanza muger*. The tree yields an exudate which is known as the *gum of the oil tree*. This is a thick, adhesive liquid, resembling copaiba, usually turbid on account of a greenish substance, which, however, finally subsides, leaving a clear, brownish-yellow liquid. For chemical study, see *A. J. P.*, Jan., 1898.

Propaesin. *Propylis Amino-benzoas. Propylamine Benzoate. Paramido-benzoic Acid Propyl Ester.*—It occurs as a white, crystalline powder, very sparingly soluble in water, but freely soluble in both alcohol and ether. Perl (*Med. Klin.*, 1909, v, p. 1892) has found it useful to relieve the pain of *sore throat*, and, internally, to quiet *vomiting* and the pain of *gastric ulcer*. The internal *dose* is approximately one to four grains (0.065–0.25 Gm.), although Cluger asserts (*Th. M.*, 1909, p. 77) that fifteen grains (1 Gm.) may be given without harmful symptoms.

Proponal. *Propal. Propytal. Dipropyl Barbituric Acid.* $(C_3H_7)_2C(CONH)_2CO$.—It occurs as colorless crystals which melt at 145° C., sparingly soluble in cold, but more so in boiling water and easily soluble in dilute alkalies. This hypnotic appears to be closely allied in its range of therapeutic usefulness, as it is in its chemical structure, to barbital. According to Bumke (*Med. Klin.*, 1906) it is one-half again as powerful a somnifacient as barbital, but Ziehen (*D. M. W.*, 1908, p. 583) found that although it was more rapid in its action it was not so certain. It appears also to be less liable to be followed by unpleasant consequences, especially by post-nocturnal drowsiness. The *dose* is from two to eight grains (0.13–0.5 Gm.).

Propyl Alcohol (normal propyl alcohol, $C_2H_5.CH_2OH$) is formed in the fermentation of certain sugar and wine residues, as from the marc of grapes, and is separated from the fusel oil of this fermentation. It is a colorless, pleasant-smelling liquid, boiling at 96° C. See also *Isopropyl Alcohol.*

Propylamine. *Mono-propylamine.* $CH_3.CH_2.CH_2.NH_2$.—For many years this compound was considered to be identical with trimethylamine, but at the present time it is known to be an entirely different product, although isomeric, and to possess distinctive properties. The boiling point of *propylamine* is 49° C., trimethylamine 93° C. Pure propylamine is a clear, highly refractive fluid, pure trimethylamine is a gas. It is generally prepared by heating propyl nitrate with a 10 per cent. alcoholic ammonia solution and is a clear alkaline fluid with a powerful ammoniacal, fishy odor, and soluble in both water and alcohol. In 1854 it was brought forward by Awenarius, of St. Petersburg, as an antirheumatic, but it is rarely used to-day for this purpose. It has also been used as a sedative in *chorea* and *hysteria. Dose,* two to five grains (0.13 to 0.32 Gm.) several times daily. As much as fifteen to forty-five grains (1–3 Gm.) has been administered in the course of a day.

Propylamine Hydrochloride. $CH_3.CH_2.CH_2.NH_2.HCl$.—Deliquescent colorless crystals, easily soluble in water. Uses and properties same as preceding. The *sulphate of propylamine,* $(CH_3CH_2CH_2NH_2)_2H_2SO_4$, well formed crystals, has also been used.

Propylene. *Propene.* C_3H_6.—This occurs in common illuminating gas and is also a by-product in the refining of petroleum. It may be prepared synthetically by heating glycerin with zinc dust. It is a gas which liquefies at −48° C.

Propylene has been suggested as a surgical anesthetic. Brown (*J. P. Ex. T.*, 1924, xxiii, 485) finds that concentrations of 37 per cent. will produce anesthesia and that in 65 per cent. it causes toxic symptoms with fall of blood-pressure. Riggs (*Proc. Soc. Exper. Biol.*, 1925, xxii, 269) finds that the anesthetic potency is considerably higher than that of ethylene and that the recovery is rapid after withdrawal. As far as we know it has not been tested on human beings.

Protea. *Protea mellifera* Thunb. (Fam. *Proteaceæ.*) *Sugar Bush.*—A large bush with linear-oblanceolate leaves, white flowers and showy involucre, indigenous to South Africa. From the leaves Merring Beck, in 1886, obtained *proteacin.* Merck and Hesse subsequently named the principle *leucodrin.* Hesse found the leaves to yield from 2 to 5 per cent. of *hydroquinone* associated with *proteacic acid.* (*P. J.*, 1896, 426.)

Protein Therapy. *Foreign protein therapy. Non-specific protein therapy.*—In 1913 Ichikawa, in studying the treatment of typhoid fever by vaccines, noted that the injection of killed typhoid bacilli was beneficial in cases of infection by the para-typhoid bacillus as well as by the typhoid bacillus. As the antibodies and antitoxins are known to be narrowly limited in their antidotal effects to single specimens or even strains of bacteria, it was surmised that the injections of killed bacteria must have some other effect upon the system than increasing the formation of specific antibodies. Subsequent studies have shown that the parenteral introduction of foreign protein increases the bodily resistance to a large number of pathogenic micro-organisms. Various foreign proteins, including killed bodies of bacteria, milk and proteose, have been employed in a considerable number of infectious diseases, in some cases with marked benefit.

The reaction to intravenous injection of a foreign protein seems to be the same no matter what the type of protein which is used. Unless the dose of the protein be large enough to call forth a fairly vigorous reaction it is not likely that there will be any beneficial effect upon the course of the infection. The typical course of the reaction is about as follows: About half an hour after the injection the patient is seized with a chill of varying severity accompanied with increase in the pulse rate, with more or less headache which may be quite severe—and often nausea and cyanosis. Within 15 to 30 minutes the chill is followed by a fever, the body temperature reaching a point sometimes as high as 105° F.; this fever lasts from a few hours to one or two days. At the time of the chill there is usually a slight reduction in the number of white blood corpuscles but soon after there occurs a great increase in the number of these cells, the leucocytosis reaching its maximum in from 4 to 12 hours after the injection. At the height of the leucocytosis there is ordinarily from 20,000 to 30,000 white cells per cubic millimeter in the blood but as high as 100,000 has been reported. This leucocytosis continues generally for 24 to 48 hours. At the time of the chill there is usually a slight increase in the blood pressure but immediately after there occurs a marked fall.

Most of the early studies of this method of treatment were made with *typhoid vaccine.* Miller (*J. A. M. A.*, 1917, lxix, 765) has reported on 175 cases of various forms of *arthritis* which were treated with this method. In the great majority of cases there was either complete cure or marked benefit in the joint conditions. Complicating endocarditis was not favorably influenced. He gave doses of from 40,000,000 to 115,000,000 killed typhoid bacilli at a dose.

Among the proteins which have been used may be mentioned especially the following: Miller (*J. A. M. A.*, 1917, lxix, 765) uses killed typhoid bacilli in doses of from 40,000,000 to 150,000,000. Gow (*B. M. J.*, Feb. 28, 1920) has employed killed bacillus coli in doses up to 50,000,000. Several authors have used the so-called *Witte's peptone* in doses of 0.5 to 1 Gm. (8 to 16 grains) usually in about a ten per cent. solution. These are generally given intravenously. Schulman (*N. Y. M. R.*, July, 1920) and others have used intramuscular (not intravenous) injections of sterilized milk in doses of 5 cc. (75 minims) and upwards. Barker and Nelson (*J. A. M. A.*, 1924, lxxii, 190) believe the reaction following milk injections is due to the bacteria in it as they failed to obtain the effect from milk of low bacterial count. Various proprietary albumoids, intended for this use, are on the market. Among these may be mentioned *Vaccineurin, Sanarthrit, Caseosan* and *Albusol.*

The following are some of the diseases in which this method of treatment has been employed. In *typhoid fever,* Kraus and Mazza, using typhoid vaccine, reported abrupt termination in about 20 per cent. of their cases and marked favorable influence in about 40 per cent. more. That these results were not due to the vaccine effect of the bacilli is shown by the fact that Ludke (*M. M. W.*, 1915, lxxii, 321) obtained equally favorable results with deutero-albumose. Miller reports 93 cases of acute arthritis, some apparently *rheumatic fever,* in 80 of whom there was marked relief of the joint symptoms. He did not observe, however, any favorable influence upon complicating endocarditis. In sub-acute and chronic *arthritis* he noted results favorable enough to justify further study of the subject. Schulman has used the method of treatment in *gonorrheal arthritis* with apparent good effect and Trossarello (*Rif. Med.*, April 3, 1920) has used it in various forms of gonococcus infections, as in *salpingitis,* with encouraging results but in urethritis, prostatitis and arthritis no apparent benefit. Cowie and Beaven (*J. A. M. A.*, 1919, lxxii, 1117) have employed the treatment in *influenzal pneumonia* but with no striking effect on the general mortality. Miller (*J. A. M. A.*, Jan. 29, 1921) has observed apparent benefit in some of his cases of *pneumonia.* Cowie (*N. Y. State J. Med.*, 1921, xxi, 395) has had favorable results in *furunculosis* and other suppurative diseases, especially in the treatment of inflammatory eye conditions as, *iritis, panophthalmitis,* etc. It has also been used in puerperal and other *septicemias, tuberculosis,* etc., but the present evidences of its value are insufficient to draw conclusions.

Prunella. *Prunella vulgaris* L. *Self-heal. Heal-all. Carpenter Weed. Brunella vulgaris. Paquerette,* Fr. *Braunelle, Braunheil,* G.—A small perennial labiate herb with 3-flowered axillary clusters of purplish to pinkish flowers arranged in a close spike. While native to Europe, it is common both in Europe and the United States. It was formerly used in *hemorrhages* and *diarrhea,* and as a gargle in *sore throat.*

Prussian Blue. *Ferri Ferrocyanidum. U. S.* 1870. *Ferri Ferrocyanuretum. U. S.* 1850. *Ferrocyanide of Iron. Ferric Ferrocyanide. Ferrocyanuret of Iron.* $Fe_4Fe_3(CN_6)_3$.—A blue amorphous powder, insoluble in water, soluble in acids and alkalies; produced by the interaction of solutions of a ferric salt and potassium ferrocyanide. It was discovered by Diesbach in 1710.

Prussian blue at one time was manufactured on a large scale by the action of fused alkali and iron salts on nitrogenous organic matter, as dried blood, but it is now prepared by electrolytic combination.

For further information concerning Prussian blue see *U. S. D.*, 20th ed., p. 1565. It is no longer used in medicine. In by-gone days it was employed as a tonic in *doses* of from three to five grains (0.20 to 0.32 Gm.), repeated several times a day, and gradually increased until some effect is produced.

Psidium. *Psidium Guajava* L., *P. pomiferum* L., *P. pyriferum* L., and other species of *Psidium.* (Fam. *Myrtaceæ.*) *Guava.*—These are shrubs or trees indigenous to tropical and subtropical America. Hartwich has examined the root, bark, and leaves of these plants from India. (See *Ph. Rev.*, 1896, 257.) The fruits, which somewhat resemble apples, are largely used as a food in the form of jelly.

Psoralea. *Scurfy Pea.*—This genus (Fam. *Leguminosæ*) is represented by about 115 species of strongly scented herbs, shrubs and undershrubs which are glandular-punctate, and possess pinnate or trifoliate leaves, racemes or spikes of blue, purple or white papilionaceous flowers with an unequally 5-toothed calyx and short, ovoid, 1-seeded pods. The tubers of *P. esculenta* Pursh. were employed by the Indians of the Northwestern United States, and by the settlers, as articles of food, being the *prairie turnip* or *prairie potato,* the *tipsinah* and *taahgu* of the Indians. C. Richardson found in it nearly 70 per cent. of starch, and 5 per cent. of a new, rapidly crystallizing sugar, which has not been further investigated. *P. glandulosa* L., *culen, yolochiahitl,* of the Mexican Pharmacopœia, yields a leaf which is used as a tonic or anthelmintic, and an emetic root. *P. bituminosa* L., of Arabia, and *P. physodes* Dougl., of California, are popularly considered tonic and emmenagogue, the former being presented under the name of *Herba Trifolii Bituminosi. P. pedunculata* (Mill.) Vail. (*P. melilotoides* Michx.) (*Congo root, Bob's root, Samson's snakeroot*), of Virginia, has been recommended as an aromatic bitter tonic, especially useful in *chronic diarrhea.* The part employed is the root, from which MacNair obtained about 2 per cent. of a volatile oil, having the specific gravity 0.93, a pungent and bitter taste, and a neutral reaction; also a bitter principle, but not tannin. For further description, see *A. J. P.*, July, 1889; also 14th and 16th editions of *U. S. D. P. corylifolia* L., of India, yields an oleoresin which is used in the treatment of *leucoderma* and other skin diseases. (*P. J.*, Sept., 1881.) Mann and Griffiths obtained from the seeds of *P. corylifolia* 13.7 per cent. of a thick brownish oil and 37.2 per cent. of an alcoholic extract which yielded by purification 9.2 per cent. of a resinoid. (*P. J.*, 1912, 260.)

Psyllium. *Semen Psyllii; Semences de Psyllium,* Fr.—This name has been applied to the seeds of several species of European *Plantago.* The best are those of *Plantago Psyllium* L., or *fleawort,* which grows in the south of Europe and in Northern Africa. They are ovoid, about 3 mm. in length, and 1 to 1.5 mm. in width, convex on one side, concave on the other, dark reddish-brown in color, shining, inodorous, and nearly tasteless, but mucilaginous when chewed. They are demulcent and emollient, and may be used internally and externally in the same manner as flaxseed, which they closely resemble in medicinal properties. They are used as a mild laxative in *chronic constipation* in *doses* of one or two teaspoonfuls 3 times a day. *Spogel seed,* used in India as a demulcent in intestinal irritation, is derived from *P. Isphagula* Roxb., probably a variety of *P. ovata* Forsk. (See *Journ. Méd. de Paris,* Sept., 1887.)

Ptelea. *Ptelea trifoliata* L. *Wafer Ash. Wing Seed. Shrubby Trefoil. Hop Tree. Orme à trois feuilles,* Fr. *Hopfenbaum, Kleebaum,* G. (Fam. *Rutaceæ.*)—This is a shrub or small tree with 3-foliate leaves growing in rocky places from Lake Ontario to Minnesota and southward.

The root bark has a peculiar somewhat aromatic odor, and a bitter, persistently pungent, and slightly acrid, yet not disagreeable taste. Within recent years the bark has been found admixed with Euonymus as well as substituted for it. It may be readily distinguished from the latter by its absence of caoutchouc fibers and by its characteristic broad transverse lenticels and waxy, pale yellow fractured surface. For structural details of *Ptelea* bark see article by H. W. Youngken in *A. J. P.*, 1918, 160. Steer obtained from it an oleoresin of an acrid and bitter taste and the alkaloid berberbine. An alkaloid, *arginine*, $C_6H_{14}O_2N_4$, is stated also to be present in the root. (*A. J. P.*, 1867, 337.) It was formerly employed among the physicians of the Western States in the treatment of *dyspepsia*, and generally in diseases requiring a mild, non-irritating, bitter tonic.

Ptomaines.—Under this name are included alkaloid-like bases obtained from animal tissue after decomposition has commenced, hence sometimes called *cadaveric alkaloids.* Bence Jones and Dupré (*Ph. Centralh.*, xvi, No. 10) first published a notice of the finding of an alkaloid-like base from a decomposing human liver. Its sulphate solution fluoresced, and in other ways resembled quinine, yielding precipitates also with the usual alkaloidal reagents, potassio-mercuric iodide, phosphomolybdic acid, and gold and platinic chlorides. It appears, however, that Marquardt had isolated such bases even previous to this. The chief investigators of this class of alkaloids have been Selmi, who first systematically studied them and gave them the name *ptomaines*, and Brieger, who in the latter part of the 19th century published a series of elaborate studies and has classified their reactions.

Brieger's researches established the fact that ptomaines are found during the earlier stages of decay, and that they are in general of a non-benzenoid character, but that as putrefaction continues they gradually disappear and give place to well-known benzenoid compounds, phenol, cresol, indol, etc. The bases are of two classes. At first are obtained oxygenated bases, like *choline*, $C_5H_{15}O_2N$, *muscarine*, $C_5H_{15}O_3N$, *neurine*, $C_5H_{13}ON$, *gadinine*, $C_7H_{18}O_2N$, and *tetanine*, $C_{13}H_{20}O_4N_2$. These seem later to disappear, and amines seem to be almost the only products. Among those mentioned, the simplest are *dimethylamine*, $(CH_3)_2NH$, *trimethylamine*, $(CH_3)_3N$, and *triethylamine*, $(C_2H_5)N_3$. A number of the others seem to be diamines, like *putrescine*, $C_4H_{12}N_2$, *cadaverine*, $C_5H_{14}N_2$, *saprine*, $C_5H_{16}N_2$, *neuridine*, $C_5H_{14}N_2$—all four discovered by Brieger in the cadaver—*collidine*, $C_8H_{11}N$, *hydrocollidine*, $C_{11}H_{13}N$, *parvoline*, $C_9H_{13}N$, and *tyrotoxicon* (*diazobenzene*), $C_6H_5N_2$, discovered by Vaughan in poisonous cheese and in ice cream which had been allowed to become stale.

Barger and Walpole (*J. P.*, 1909, xxxvi) separated from putrescent horse meat *parahydroxyphenylethylamine* which is formed by the decomposition of tyrosine (see *Tyramine*). This base also occurs in ergot. Dale and Dixon (*J. P.*, xxxix) have shown that this base as well as *isoamylamine*, which also occurs in putrescent meat, acts upon the system like adrenalin, causing marked rise in the blood pressure.

Brouardel and Bontury (*C. R. A. S.*, xcii, 1056) state that ptomaines can be distinguished from the vegetable alkaloids by their reaction with potassium ferricyanide. This salt when treated with a solution of a pure vegetable alkaloid is unaffected by it; while, under the same conditions, it is instantly reduced to the state of ferrocyanide by a ptomaine, and thus becomes capable of forming Prussian blue with a ferric salt. Up to the present but two exceptions to this rule have been found—morphine, which readily reduces potassium ferricyanide, and veratrine, which gives traces of such reduction. It is possible, however, that in this last case the reducing action is due to certain impurities which the investigators were unable to remove completely from the veratrine employed by them.

Ptomaines are not used as medicines, but are of great interest to the toxicologist, not only from a chemical standpoint, but also from the fact that many are violently poisonous. The well-known action of putrescent flesh, the curious poisonings sometimes produced by certain crustaceans and mollusks which feed upon carrion, are in all probability caused by them. Salkowski and Brieger found in living mussels a ptomaine that they named *mytilotoxine.* (See *Musculus.*) In regard to treatment of poisoning by putrid animal matters, our present knowledge only justifies the immediate evacuation of the stomach and bowels and the meeting of the various indications as they arise. For fuller information as to the formation of ptomaines, their detection, separation, and clinical features, see *Ptomaines and Other Animal Alkaloids*, by A. C. Farquharson, M.D., Bristol, Eng., 1892.

Pulmoform. *Methylene-diguaiacol.*

$$CH_2\left\langle\begin{matrix}C_6H_3(OCH_3)(OH)\\ C_6H_3(OCH_3)(OH)\end{matrix}\right.$$

This is a yellow tasteless powder obtained by the action of formaldehyde upon guaiacol. It is used as a substitute for creosote, especially in the treatment of *chronic bronchitis* and *tuberculosis.* The *dose* is eight grains (0.5 Gm.).

Pulmonaria. *Pulmonaria officinalis* L. *Lungwort. Pulmonaire*, Fr. *Lungenkraut*, G. (Fam. *Boraginaceæ.*)—An herbaceous perennial, European plant having tufts of ovate-oblong, coarsely hairy, spotted leaves and cymes of red flowers fading to violet. It is commonly cultivated. The leaves have been employed in *catarrh, hemoptysis,* and *consumption*, but their virtues are doubtful.

Purgatol. *Purgatin. Anthrapurpurine-diacetate. Diacetyl Ester of Anthrapurpurine*, or *Trioxyanthraquinone.* $C_{14}H_5(OH)(OC_2H_3O)_2.O_2$.—This substance occurs as an orange-colored crystalline powder, melting at 175° to 178° C., insoluble in water and in dilute acids, but slowly soluble in weak alkali and splitting up with development of a deep violet-red coloration.

Purgatol is said to be a laxative similar to emodin, to which it is chemically allied. It is absorbed to some extent, causing the urine to become red. It has been recommended in *chronic constipation* in *doses* of eight grains (0.5 Gm.), increased if necessary, and is said to act in from three to twelve hours without pain.

Pycnanthemum. *P. flexuosum* (Walt.) Bsp. (*P. linifolium* Pursh., *Koellia flexuosa* (Walt.) MacM.) *Mountain Mint. Basil. Dysentery Weed.*—This American mint was popularly used in bowel complaints; its hot infusion is diaphoretic. (See *A. J. P.*, 1894, 65, 169; *Ph. Rund.*, 1896, 32.)

The volatile oil from *P. lanceolatum* Pursh. contains carvacrol, pulegone, geraniol, dipentene, and terpenes, and a second ketone, probably thujone. The carvacrol content runs from 14.5 to 58 per cent., usually 25 per cent. or more. (*Chem. Abstracts*, 1918, xii, 1410.)

Pyocyanase.—This is the name which is given to a solution of bacterial proteids, obtained by the process of autolysis, from the *Bacillus pyocyaneus.* The method of preparation is as follows: The bacilli are grown in bouillon until they cause to multiply; this cessation of growth is believed to be due to the production of a ferment which eventually leads to a solution of the bodies of the bacteria. The bouillon is then filtered through porcelain filters to free it from any bacteria which may be present. This solution contains a substance which has the power of dissolving not only the *Bacillus pyocyaneus,* but many other forms of bacteria, including those which cause diphtheria, typhoid fever, streptococci, etc. The tubercle bacillus, however, does not appear to be affected by it. Muhsam (*D. M. W.,* 1908, xxxiv, 231) added one drop of *pyocyanase* to eighty minims (5 cc.) of a bouillon culture of diphtheria and found that in twenty-four hours these germs were all destroyed. He also injected into guinea-pigs 2 cc. of diphtheria culture to which was added at the time of inoculation from one to five drops of pyocyanase and found that in every instance the latter protected the animals against the acquirement of the disease.

Pyocyanase has been used as a local antibacterial agent in a number of conditions. It has been found serviceable when applied directly to the membranes in cases of *diphtheria,* and is stated to be capable of sterilizing the throat. It has also been employed with asserted good results in various other suppurative and infectious conditions of the mouth, nose and throat. Pringsheim (*Med. Klin.,* 1909, p. 1678) dissents from the chorus of praise and states that it is not superior in its practical effects to other disinfectants in common use. Bernbach (*M. M. W.,* 1908, lv, 120) finds that when injected subcutaneously it is followed by local redness, swelling and pain, and chill followed by a fever reaching as high at times as 40° C., which ends in five hours with a critical sweat.

Pyocyanase is applied either by means of a swab or an atomizer, from fifty to eighty minims (3.0–5.0 cc.) being used.

Mavinaveitia has separated the blue coloring matter formed by these bacteria to which he gives the name *pyocyanin.* (*D. C.,* 1917, lxi, 132.)

Pyoktanin Mercury.—A combination of mercury, with methyl violet. It forms a violet powder almost insoluble in water and alcohol. It is used as an antiseptic in *gonorrhea* in 1–2000 solutions and in *burns,* diluted with equal amounts of starch.

Pyoktanin Yellow. *Imino-tetramethyl-diamido diphenyl-methane Hydrochloride. Apyonin. Medicinal Auramine,* $C_{17}H_{21}N_3HCl$.—This is a yellow powder insoluble in water and alcohol, used as an antiseptic in *skin diseases* and in ophthalmic practice. It is used as a dusting powder, 1 or 2 per cent., or 2 to 10 per cent. ointments.

Pyramidon Camphorate.—There are two combinations of camphoric acid with pyramidon on the market. The neutral pyramidon camphorate, $(C_{13}H_{17}N_3O)_2C_{10}H_{16}O_4$, is a white, crystalline powder, fusing between 80° and 90° C., soluble in 15 parts water and 2 parts alcohol. The acid camphorate (*pyramidon bicamphorate*), $C_{13}H_{17}N_3O.C_{10}H_{16}O_4$, has a faintly acid reaction, fuses between 84° and 94° C., and is soluble in twenty parts of water or four of alcohol. The purpose of these combinations is to overcome the tendency of pyramidon to produce excessive sweating, indeed it is asserted that the bicamphorate is useful to control the *night sweats* of *phthisis.* The two salts are used for much the same purposes as pyramidon. *Dose,* of either, is eight to fifteen grains (0.5–1.0 Gm.).

Pyramidon Salicylate. *Amidopyrine Salicylate.* $C_{13}H_{17}N_3O.C_7H_6O_3$.—This substance has been proposed as a substitute for the older salicylates, and may be used in their stead in subacute and chronic cases. The *dose* is eight to twelve grains (0.5–0.75 Gm.).

Pyranum. *Pyrenol. Thymol-sodium Benzoyloxybenzoate.*—This is a white, hygroscopic, crystalline powder with an aromatic odor and a sweetish taste. It dissolves readily in water, one part to five, and in alcohol, one part to ten. This substance, which apparently undergoes change in the system (salicylic acid and thymol having been detected in the urine after its administration), was brought forward by Schlesinger (*Th. M.,* Feb., 1903) as an antipyretic and antineuralgic. He used it in various forms of fevers and asserts that it is superior to salicylic acid in acute *rheumatism,* and has very remarkable analgesic properties. Burchand (*Ther. Geg.,* 1905) recommends pyranum in *hysteria* and *neurasthenia. Dose,* fifteen grains (1 Gm.) repeated up to forty-five grains (3 Gm.) in a day, if required.

Pyridine. C_5H_5N.—*Pyridine* is the first of a series of homologous bases which are found in coal tar naphtha, in shale oil, in peat tar, in tobacco smoke, and more especially in the product known as *Dippel's oil,* obtained by the distillation of bones and other animal matter. Pure pyridine is a colorless liquid, with a powerful and persistent odor, of sp. gr. 0.9746, and boils at 116° to 118° C. It is miscible with water in all proportions, but is precipitated from its solution by excess of sodium hydroxide. It is also miscible with alcohol, ether, chloroform, benzene, and fatty oils. It is used as a solvent in the rubber and paint industries. It has been used as an antiseptic and germicide, and is employed as one of the constituents for "denaturing" alcohol for manufacturing uses. In toxic dose pyridine is a violent poison, producing cyanosis, methemoglobinemia, great muscular weakness from paralysis both of the motor centers and nerves, and finally death from failure of respiration. De Renzi asserts that in small doses it stimulates the heart, increases the blood pressure, and is a useful remedy in *angina pectoris.* It was first introduced into practical medicine, as a remedy for *asthma,* by Germain Sée, whose statement has since been confirmed by various clinicians. Sée employed it by exposing about a drachm upon a plate in a small room, in which the patient remained from twenty to thirty minutes, the process being repeated several times a day; or from five to ten minims in two ounces of water may be taken by an atomizer; or five minims may be inhaled directly. De Renzi has given it internally in the daily *dose* of six minims (0.3 cc.) gradually increased to twenty-five (1.6 cc.). Under the name of *pyrilin* is marketed a solution of *pyridin ethylphosphinate,* recommended in diseases of the air passages.

Pyridine Tricarboxylic Acid. $C_5H_2(COOH)_3N$.—This derivative of pyridine may be prepared by the oxidation of methyl-pyridine (*picoline*), or is obtained from certain natural alkaloids, such as quinine, quinidine, and cinchonidine, by boiling with an alkaline solution of potassium permanganate. It forms prisms melting at 244° C. This substance is said to be an active antiseptic and antipyretic, and was recommended by Rademaker (*Medical Herald*, 1887) in *malaria, asthma* and *typhoid fever*, in *doses* of from one to ten grains (0.06–0.6 Gm.).

Pyrochinin is a quinine-pyramidon double salt of camphoric acid, containing 43 per cent. quinine, 30 per cent. pyramidon and 26 per cent. camphoric acid. It has been proposed as an antipyretic and analgesic.

Pyrosal. $C_9H_8O_5C_{11}H_{12}N_2O$.—*Antipyrine acetylsalicylate* forms colorless needles or plates of an acid but not bitter taste which are difficultly soluble in water. *Pyrosal* is said to contain about 50 per cent. of antipyrine, 36 per cent. of salicylic acid, and 14 per cent. of acetic acid. It is asserted to be broken up in the intestinal canal into its constituents, and to exert their influence in the human system, and has been used in *polyarthritis*, severe *influenza, febrile cystitis, migraine*, and *sciatica*, in *doses* of from eight to fifteen grains (0.5–1.0 Gm.), from two to six times daily.

Quamacai.—The wood of *Paullinia thalictrifolia* Juss. (Fam. *Sapindaceæ*), a twining shrub indigenous to Brazil, has been used in *beri-beri* and *rheumatic affections*. It is also used externally in diaphoretic baths.

Quebracho Bark. *Aspidosperma, U. S. IX.*—The name quebracho is derived from the two Spanish words, *quebrar* and *hacha*, signifying "The axe breaks." There are several trees whose wood is hard and to which the term "quebracho" is popularly applied, among others the *Thouinia striata* (Fam. *Sapindaceæ*). The name *quebracho colorado* is applied to the *Schinopsis Lorentzii* (Griseb.) Engl. (Fam. *Anacardiaceæ*) which grows in Argentine. The wood of this plant yields as extract which is largely used in tanning of leather. Perkin and Gunnel (*A. J. P.*, 1896) found in it also a yellow coloring matter apparently identical with fisetin (see *Fustic*). Under the name of "quebracho flojo," the wood and bark of *Iodina rhombifolia* Hook. et Arn. (Fam. *Santalaceæ*) are substituted and sold for quebracho colorado in Southern Brazil, Argentina and Uruguay.

Quebracho blanco is the popular name for the *Aspidosperma quebracho-blanco*, which was formerly official. This is a large evergreen tree which sometimes reaches the height of one hundred feet, and is remarkable for its erect stem and its wide-spreading crown reaching out over the cacti and lower bushes among which it grows. The tree is indigenous to the western provinces of Argentine and is also found growing in Chili, Bolivia and Southern Brazil. The bark has been used for a long time in South America as a febrifuge but was not introduced into Europe until about 1878. The commercial supply of the drug used in the United States comes from the Argentine Republic.

Quebracho bark is remarkable for the extreme thickness of the corky layer which often constitutes more than half of its entire substance, and is separated from the lower layer by a more or less sharply defined outline. The corky layer is usually externally dirty gray, or where it has been rubbed appears yellowish-red. "In irregular chips or in longitudinal pieces attaining a length of 14 cm. and a thickness of 35 mm.; outer corky layer from 3 to 25 mm. in thickness, brownish-gray or reddish-brown and deeply furrowed, frequently somewhat reticulate with longitudinal and shallow transverse fissures, the crevices being occasionally lined with the mycelia of a grayish mould; outer surface of bark, from which the cork has been separated, light brown or reddish-brown and usually more or less roughened; inner surface occasionally with adhering wood, otherwise light yellowish-brown to light reddish-brown, longitudinally finely striate and finely porous; fracture short-fibrous with projecting bast-fibers; nearly inodorous, taste bitter and slightly aromatic. Under the microscope, transverse sections of Aspidosperma show a number of successive layers of cork separated by large groups of stone cells, isolated bast-fibers and parenchyma; inner bark with starch-bearing medullary rays 1 to 5 cells in width, separating narrow wedges composed of large prominent groups of stone cells in which are occasionally included one or more thick-walled bast-fibers; bast-fibers usually single, very thick-walled, strongly lignified and surrounded with crystal fibers and starch-bearing parenchyma. The powder is reddish-brown; bast-fibers single, very long and surrounded by crystal fibers, the crystals being in prisms frequently terminated by pyramids and from 0.008 to 0.03 mm. in length; stone cells in large thick groups composed of numerous more or less tabular cells; cork cells more or less polygonal in outline with thick, slightly lignified walls; starch grains single or 2- to 4-compound, the individual grains spherical, ovoid or more or less plano-convex, from 0.003 to 0.025 mm. in diameter." *U. S. IX.*

In 1878, Fraude (*B. Chem. G.*, 1878, p. 2189; 1879, p. 1560) discovered in the quebracho blanco an alkaloid, *aspidospermine*, $C_{22}H_{30}O_2N_2$, but Hesse has found five other alkaloids, *aspidospermatine*, $C_{22}H_{28}O_2N_2$, and isomeric with it *aspidosamine*, $C_{22}H_{28}O_2N_2$, *quebrachine*, $C_{21}H_{26}O_2N_2$, and isomeric with this *hypoquebrachine*, $C_{21}H_{26}N_2O_2$, and *quebrachamine*, *quebrachol*, $C_{20}H_{34}O + H_2O$, *quebrachit*, $C_6H_{11}(OCH_3)O_5$. (*Ber. d. Chem. Ges.*, xiii, 2308.) A. J. Ewins (*Tr. Chem. Soc.*, 1914, p. 2738) investigated aspidosperma, but could not confirm the list of alkaloids found by Hesse, with the exception of aspidospermine and quebrachine. He believes that the other alkaloids reported are decomposition products of aspidospermine and quebrachine. According to Fourneau and Page (*Bull. Sci. Pharm.*, 1914, xxi, 7), quebrachine is identical with yohimbine.

Aspidospermine is a brownish-yellow amorphous powder or needle-shaped crystals, fusing at 205° to 206° C., is soluble in about 6000 parts of water at 15° C., the solution having a decidedly bitter taste, soluble in about 48 parts of absolute alcohol, in 106 parts of ether, insoluble in glycerin; it dissolves readily in fats and fixed oils, cod liver oil dissolving a larger proportion than it does of quinine. Its sulphate and hydrochloride are very soluble in water. The citrate is crystallizable, and very soluble. The yield of aspidospermine is small, 0.33 per cent. of the bark. *Aspidospermatine* is crystalline, and fuses at 162° C.; *aspidosamine* is amorphous, and fuses at 100° C.; *quebrachine* in colorless crystals fuses at 214° to 216° C.; *hypoquebrachine* is a yellowish mass resembling albumin, and fuses at 80° C.; *quebrachamine* forms colorless silky needles, only slightly soluble in alcohol, ether, chloroform, and benzin, and fuses at 142° C. Vanderkleed reports two samples of quebracho assaying 0.95 and 1.22 per cent. of alkaloids respectively. (*J. A. Ph. A.*, 1915, p. 983.) Newcomb reports the ash content of aspidosperma to range from 5.9 to 6.8 per cent. (*A. J. P.*, 1915, p. 115.) Two new sugars have also been extracted by Tanret, *quebrachite* and lævogyrate inosite. Tannin and starch have also been found in the bark. According to H. C. Wood, Jr., the most important principle is quebrachine. (*U. P. M. B.*, 1910, xxiii.)

When a preparation of aspidosperma is injected into the circulation it causes an enormous increase in the rate and depth of the respiration with some fall in the blood pressure. Pentzold, who first described the effects of this drug on the respiration, believed that the breathing was dyspneic in type and that the drug acted by preventing the red corpuscles from giving up their oxygen. He based his belief on the fact that after death from the poison the blood had the same color in both arteries and veins, but Wood and Hoyt (*U. P. M. B.*, Sept., 1903) showed that the blood retained its normal oxidizing powers after aspidospermine and believed that the arterial hue in the veins was due to the violence of the respiration. The fall of blood pressure is due primarily to weakness of the heart, although larger doses also cause dilatation of the blood vessels—according to Cow (*J. P. Ex. T.*, 1914, v, p. 341), by a depressant action on the medullary centers. The increase in the respiration which is the most marked effect of aspidosperma appears to be due to a direct action upon the respiratory center as H. C. Wood, Jr. (*U. P. M. B.*, 1910, xxiii), has shown that it does not affect the circulation in the lungs, and Cow that it does not affect the bronchioles.

All of the alkaloids of aspidosperma as far as they have been studied are possessed of similar physiological properties, although to different degree. Both Wood and Cow agree that quebrachine is the most active alkaloid in the drug.

Aspidosperma is used in medicine for the relief of various types of dyspnea, especially in *emphysema* and *asthma*. In the latter condition it is not generally useful to interrupt the paroxysm, but in many cases if used continuously will greatly reduce the frequency and severity of attacks.

Under the name of *amorphous aspidospermine* there has entered in commerce a mixture of the various alkaloids of this drug. *Dose* of this preparation is from a quarter to one grain (0.016–0.065 Gm.); that of the crystalline aspidospermine is from one-fortieth to one-twentieth of a grain (0.0016–0.003 Gm.).

The fluidextract (*Fluidextractum Aspidospermatis*) was formerly official. *Dose*, fifteen minims (1 cc.).

Quina Morada.—This drug, growing in Bolivia and the Argentine Republic, and there credited with the therapeutic values of cinchona is produced by *Pogonopus Tubulosus* (Rich.) K. Sch. (Fam. *Rubiaceæ*). It has been studied by Arata and Canzoneri, who find in it a blue fluorescent substance, *moradin*, and an alkaloid, *moradeine*. (*P. J.*, April, 1890.)

Quinanaphthol. *Quinaphthol. Quinine-beta-naphthol-monosulphonate.* $C_{20}H_{24}O_2N_2.(OHC_{10}H_6.SO_3H)_2$.—This is a yellow crystalline powder, soluble in alcohol and water. It fuses at 185° to 186° C., and contains 42 per cent. quinine. It is used in *typhoid fever, intestinal tuberculosis, dysentery* and *acute rheumatism* in *doses* of five to fifteen grains (0.3–1 Gm.).

Quinate of Urea. *Urol. Urea Quinate.* $C_7H_{12}O_6.2CO(NH_2)_2$.—A combination of two molecules of urea and one of quinic acid. It forms prismatic crystals melting at 106° to 107° C. It is recommended by Van Noorden in *doses* of thirty to forty-five grains (2–3 Gm.) dissolved in a tumblerful of hot water, on rising, and going to bed, as a solvent for uric acid.

Quinic Acid. *Acidum Quinicum. Kinic Acid. Hexahydro-tetraoxybenzoic Acid.* $C_6H.H_6.(OH)_4.COOH$.—Forms colorless, rhombic prisms, easily soluble in water, difficultly soluble in strong alcohol, which fuse at 162° C. Found naturally in cinchona bark, in the coffee bean, and other sources. Led by the belief that the decrease in the elimination of uric acid, which is said to be produced by strawberries, is due to *quinic acid*, Weiss, of Basel, experimentally determined that quinic acid checks the formation of uric acid in the body, and was led to propose it and its salts as remedies in the treatment of *gout*. This theory of the action of quinic acid is certainly not established and of doubtful correctness, but has given rise to practical trials of quinates by various clinicians in gout with asserted good results. Quinic acid is converted in the system, first into benzoic, and second into hippuric acid. Various combinations of quinic acid have appeared in commerce, often under proprietary names among which are urosin, urol, chinotropin, sidonal and new sidonal; these are described elsewhere in this work.

Quinine Acetyl Salicylate. *Quinine Aspirin. Xaxaquin.*—Acetyl salicylate of quinine, $CH_3.CO.O.C_6H_4.COOH.C_{20}H_{24}O_2N_2$, is a white, crystalline powder, sparingly soluble in water, more readily in alcohol and in chloroform; melting point 157° C. It has been used by Rivolta in *pleurisy*. Boshuwers has used it (*Ther. Neu.*, March, 1908) as a symptomatic remedy in *influenza* and *tonsillitis*. The *dose* is three to ten grains (0.2–0.65 Gm.).

Quinine Æsculinate (Neutral). *Escoquinine.*—It is stated to be prepared by chemically combining quinine with esculin, the glucoside obtained from the common horsechestnut, *Æsculus Hippocastanum* L. It is a yellowish, amorphous, water insoluble powder, bitter tasting and containing 50 per cent. quinine. It is claimed to have been used with signal success in the treatment of *catarrh* and lung complications. *Dose*, one and one-half to three grains (0.096–0.2 Gm.).

Quinine Antimonate.—A white powder insoluble in water. It is used in the treatment of *rheumatism, gout, herpes*, etc. *Dose*, one and one-half to seven grains (0.096–0.45 Gm.).

Quinine Arrhenalate. *Quinine Methyl-arsenate. Quinine Monomethyl-arsenate.* $(C_{20}H_{24}O_2N_2)_2AsO.(OH)_2CH_3$.—This salt forms colorless, bitter crystals, fusing at 139° to 141° C., which are insoluble in cold and slightly soluble in warm water.

Quinine Arsenate. *Quininæ Arsenas.* $2(C_{20}H_{24}O_2N_2).H_3AsO_4 + 8H_2O$.—Made by precipitating a solution of 10 parts of quinine hydrochloride in 200 parts of water with a solution of 3.9 parts of sodium arsenate dissolved in 100 parts of water. The precipitate is washed and purified by recrystallization. It forms white, prismatic crystals, slightly soluble in cold water, very soluble in hot water. The salt contains 69.39 per cent. of quinine and 12.30 per cent. of arsenic acid. *Dose*, one-fifteenth to one-eighth of a grain (0.004–0.008 Gm.).

Quinine Eosolate. *Quininæ Eosolas.* $C_9H_7S_3O_{12}(C_{20}H_{24}O_2N_2)_2$.—This is the commercial name of the neutral quinine salt of *trisulpho-acetyl-creosote*. Very active anti-periodic properties have been claimed for it. *Dose*, three to eight grains (0.2–0.5 Gm.) three times a day.

Quinine Glycero-phosphate. *Quininæ Glycerophosphas. Kineurine, Neo-quinine.*—This salt was formerly recognized by the N. F., but was dropped at the last revision. It represents about 72 per cent. of quinine. It was officially described as follows: "Quinine Glycerophosphate occurs as fine, white crystalline needles or as a powder; odorless and having a very bitter taste. One gramme dissolves in about 850 cc. of water, or 75 cc. of alcohol at 25° C.; very soluble in boiling alcohol; very slightly soluble in chloroform or ether; soluble in 20 parts of a mixture of one volume of alcohol and two volumes of chloroform. Quinine Glycerophosphate slowly loses part of its water of crystallization at room temperature and when heated to 100° C. becomes anhydrous. Incinerate 0.2 Gm. of the salt; no weighable residue remains. The salt yields a clear solution with diluted sulphuric acid. An aqueous solution is not fluorescent, but becomes so upon the addition of a few drops of diluted sulphuric acid. Add 1 cc. of bromine T.S. to 10 cc. of a saturated aqueous solution of the salt, and then follow with 1 cc. of ammonia water; the liquid acquires an emerald-green color. When the salt is heated with potassium bisulphate the odor of acrolein is given off. An aqueous solution of 0.1 Gm. of the salt in 10 cc. of distilled water, made with the aid of acetic acid, does not produce a precipitate on the addition of ammonia oxalate T.S. (*calcium*). Dissolve 0.1 Gm. of the salt in 10 cc. of diluted hydrochloric acid; the solution does not become more than faintly turbid upon the addition of a few drops of barium chloride T.S. (*sulphate*). Dissolve 0.1 Gm. of the salt in 10 cc. of diluted nitric acid; the solution is not rendered more than faintly turbid on the addition of silver nitrate T.S. (*chloride*). Add a slight excess of ammonia water to a saturated aqueous solution of the salt, and filter; the clear filtrate does not show more than a slight turbidity with magnesia mixture T.S. (*phosphate*). Mix about 2.5 Gm. of the salt in a separatory funnel with 15 cc. of distilled water, add 5 cc. of ammonia water, shake with three successive portions of 25, 15 and 10 cc. of chloroform, respectively, and evaporate the chloroform solutions to dryness on a water bath. Dissolve 1.5 Gm. of this dry residue in 25 cc. of alcohol, add 50 cc. of hot distilled water, neutralize the liquid with normal sulphuric acid V.S., using methyl red T.S. as indicator and evaporate the liquid to dryness on a water bath. Powder the residue, mix it with 20 cc. of distilled water and maintain the temperature of the mixture at 65° C., for thirty minutes, agitating frequently. Now cool the mixture to 15° C., macerate it at this temperature for two hours with occasional shaking, then filter it through a dry filter, of from 8 to 10 cm. in diameter, into a dry test tube. Transfer 5 cc. of this filtrate to a test tube and mix it gently (without shaking) with 7 cc. of ammonia water, which must contain not less than 10 per cent. nor more than 10.2 per cent. of NH_3, must have a temperature of 15° C., and be added at once. A clear liquid is produced (*other cinchona alkaloids*). If the temperature during the maceration has been 16° C., add 7.5 cc. of ammonia; if 17° C., add 8 cc." *N. F. IV.* This substance has been recommended as an antiperiodic in *doses* of five to ten grains (0.32–0.65 Gm.). The tonic *dose* is set down as one and one-half to three grains (0.096-0.2 Gm.).

Quinine Salicylate. *Quininæ Salicylas,* U. S. IX; $C_{20}H_{24}O_2N_2.C_7H_6O_3+H_2O$. *Salicylate de Quinine Basique,* Fr. *Chininsalicylat. Salicylsaures Chinin,* G. *Salicilato quinico,* Sp.—Quinine salicylate may be made by adding a solution containing 3.9 parts of sodium salicylate dissolved in 30 parts of water, to a hot solution made by dissolving 10 parts of quinine sulphate in 75 parts of boiling water. The precipitate is collected, washed and dried and recrystallized from its solution in alcohol.

It was officially described as in "colorless, odorless needles, having a bitter taste, permanent in the air. It often assumes a pinkish color on keeping. One Gm. of Quinine Salicylate dissolves in 14 mils of alcohol, 13 mils of glycerin, 25 mils of chloroform, and in 160 mils of ether at 25° C.; slightly soluble in water. Its saturated aqueous solution is alkaline to litmus and when this solution is treated with a drop of ferric chloride T.S., a violet color develops. Add 1 or 2 drops of bromine T.S. to 10 mils of an aqueous solution of Quinine Salicylate and then introduce an excess of ammonia water; an emerald-green color is produced due to the formation of thalleioquin. Quinine Salicylate loses not more than 5 per cent. of its weight when dried to constant weight at 100° C. Incinerate about 2 Gm. of Quinine Salicylate; not more than 0.05 per cent. of ash remains. Shake about 0.4 Gm. of the salt with 20 mils of distilled water and 1 mil of nitric acid; separate portions of 10 mils each of the filtered solution are not rendered more than slightly turbid by the addition of a few drops of barium chloride T.S. (*sulphate*), nor more than slightly opalescent by a few drops of silver nitrate T.S. (*chloride*). Mix 2.21 Gm. of Quinine Salicylate in a separator with 10 mils of distilled water, add 5 mils of ammonia water, and shake the liquid with three successive portions of 25, 20 and 10 mils, respectively, of ether. Evaporate the combined ether solutions to dryness on a water bath, dissolve the residue in 20 mils of alcohol, dilute it with 50 mils of hot distilled water, and neutralize the liquid with normal sulphuric acid V.S., using methyl red T.S. as indicator. Evaporate it to dryness on a water bath, powder the residue, mix it with 20 mils of distilled water in a test tube, and complete the test for other cinchona alkaloids as directed under *Quininæ sulphas.*" *U. S. IX.*

Under the name of *Quinisal* has been introduced a compound of quinine with salicylo-salicylic acid (see *Diplosal*). This is a fluffy crystalline powder practically insoluble in water but decomposes in the presence of either acids or alkalies into its constituents. It represents a still larger proportion of salicylic acid than the normal salicylate which is rather to be regarded as a disadvantage.

Quinine salicylate represents approximately 27 per cent. of salicylic acid, and 69 per cent. of anhydrous quinine. It is believed by many practitioners to be a valuable remedy in the advanced stages of an *acute rheumatism,* in *subacute rheu-*

matism, and in mild *gouty* conditions, but the proportion of salicylic acid seems too small to exercise any pronounced effect on the system.

Dose, from five to ten grains (0.32–0.65 Gm.).

Quinine Salts.—A number of salts of quinine whose effects do not differ materially from those official and whose advantage is very doubtful, have been put on the market; they are used for the same purposes and in practically the same dosage as the official salts. In addition to those described elsewhere in this work the following seem to merit a brief word of mention of their physical properties:

Quinine Acetate, $C_{20}H_{24}O_2N_2.C_2H_4O_2$.—White crystals of a somewhat acetous odor, sparingly soluble in cold water, soluble in alcohol; 84.38 per cent. quinine. It is said also to possess diuretic properties.

Quinine Benzoate. $C_{20}H_{24}O_2N_2.C_7H_6O_2$.—White crystalline powder, soluble in about 350 parts of water; 72.65 per cent. quinine. Incompatible with either alkalies or acids.

Quinine Bitartrate, $C_{20}H_{24}O_2N_2.C_4H_6O_6$.—White crystals, slightly soluble in water or alcohol; 81 per cent. of quinine.

Quinine Citrate.—Varies somewhat in its composition; generally occurs as white crystals, sparingly soluble in water; represents from 72 to 87 per cent of quinine.

Quinine Carbonate. Acid Carbonate of Quinine. $C_{20}H_{24}O_2N_2.H_2CO_3 + H_2O$.—Fine, needle-like crystals soluble in water or alcohol; 73.66 per cent. of quinine. The neutral carbonate is described under *Aristochin.*

Quinine Ferrocyanide. Quinine Hydroferrocyanide. $(C_{20}H_{24}O_2N_2)_4H_4Fe(CN)_6 + 7H_2O$.—Yellow powder very slightly soluble, represents 79.13 per cent. of quinine. It is used in *night-sweats.*

Quinine Formate. Quinoform. $C_{20}H_{24}O_2N_2CH_4O_2$.—White crystals, neutral in reaction, soluble in water or alcohol; 87.6 per cent. of quinine. Especially suited for hypodermic use.

Quinine Hydrochlorsulphate. Quinine Chlorhydrosulphate. $(C_{20}H_{24}O_2N_2)_2H_2SO_4(HCl)_2 + 3H_2O$.—Colorless or faintly yellowish crystals, soluble in 1 part of water; 74.23 per cent. of quinine. Its solutions are acid.

Quinine Hydrofluoride. Quinine Fluoride. $C_{20}H_{24}O_2N_2.HF$.—White powder or crystals, insoluble in water, soluble in alcohol; 94.17 per cent. quinine. Used also in *rickets.*

Quinine Iodide. Quinine hydriodide. Quinine hydriodate. $C_{20}H_{24}O_2N_2HI$.—Pale yellow crystals, slightly soluble in water, freely in alcohol; 71.71 per cent. of quinine.

Quinine Iodohydriodide. Iodized Quinine Hydriodide. Quinine Periodide. $C_{20}H_{24}O_2N_2HI + I_2$.—A reddish-brown amorphous powder, insoluble in either water or alcohol: 45.9 per cent. of quinine. Used chiefly for iodide effect in *syphilis* and *rheumatism.*

Quinine Diiodide. Acid Quinine. Hydriodide. $C_{20}H_{24}O_2N_2.2HI + 5H_2O$.—Yellowish crystals or scales, soluble in 20 parts of water; 48.4 per cent. quinine.

Quinine Lactate.—Soluble in 6 parts of water, very soluble in alcohol: 78.26 per cent. of quinine. Also used locally in *gonorrhea.*

Quinine Phosphate. $C_{20}H_{24}O_2N_2.H_3PO_4 + 8H_2O$.—colorless crystals, soluble in water or alcohol; it represents from 70 to 77 per cent. of quinine according to varying amount of water of crystallization.

Quinine Tartrate. $(C_{20}H_{24}O_2N_2)_2C_4H_6O_6 + 2H_2O$.—Colorless crystals, slightly soluble in water, soluble in alcohol; 77.7 per cent. quinine.

Quinine Urate was thought by Pérayre, of Bordeaux, to be peculiarly efficacious in obstinate intermittents. It is prepared by boiling 10 parts of crude quinine in water, adding gradually 20 parts of crystallized uric acid, and, after sufficient ebullition, filtering and evaporating. A yellow salt is obtained, sometimes amorphous, more frequently crystalline, soluble in hot and less so in cold water, and, according to the author, capable of curing intermittent fever in smaller doses than the sulphate, with less cerebral disturbance, less bitterness, and easier tolerance by the stomach. (*J. P. C.*, 3e sér., xxxvii, 139.)

Quinine Valerate. *Quininæ Valeras. Quinine Valerianate.*—This salt was official in the N. F. IV, as an ingredient in the elixir of quinine and strychnine valerate. As the amount of valeric acid represented was so small as to be incapable of modifying the effect of the alkaloids, this elixir has very properly been omitted. The salt which represents approximately 73 per cent. of quinine was described as follows: "Quinine Valerate occurs as white, lustrous crystals, having an odor of valeric acid and an intensely bitter taste. It is sparingly soluble in cold water, soluble in hot water, becoming less soluble with age on account of loss of valeric acid; readily soluble in alcohol. Its aqueous solution is neutral or slightly alkaline to litmus. Add a few drops of bromine water to 10 cc. of an aqueous solution of the salt (1 in 1000), then add an excess of ammonia water; an emerald-green color is produced. An aqueous solution of the salt, acidulated with sulphuric acid, exhibits a blue fluorescence and has the odor of valeric acid. Incinerate 1 Gm. of Quinine Valerate; not more than 0.1 per cent. of ash remains. About 0.1 Gm. of the salt dissolves in 5 cc. of sulphuric acid without producing more than a light yellow color (*readily carbonizable impurities*). Ten cc. portions of the cold, saturated aqueous solution of the salt do not give more than a slight turbidity with barium chloride T.S. when acidulated with hydrochloric acid (*sulphate*); nor with silver nitrate T.S. when acidulated with nitric acid (*chloride*). To test this salt for excessive amounts of *other cinchona alkaloids* proceed as directed under *Quininæ Glycerophosphas.*" *N. F. IV.*

Quiniodol.—This is made by treating powdered red cinchona bark with an ethereal solution of iodine. Two strengths are made containing respectively 5 and 10 per cent. of iodine. It is employed as a surgical dusting powder for infected *wounds.*

Quinoa.—The *Chenopodium Quinoa* Willd. (Fam. *Chenopodiaceæ*), is largely cultivated in Southern Peru and Southern Chili, often above the elevation at which barley and rye will ripen, for the sake of its seeds. These are about the size of white mustard seeds, but flatter, and afford a flour resembling somewhat oatmeal. The starch grains are very small, and constitute about 40 per cent. of the seed, which also contain 5 per cent. of sugar, 7.5 of casein, and 11 of albumen and other protein compounds. One variety, the *red quinoa,* contains a bitter principle in the seed husks, and is used to some extent as an emetic and antiperiodic. (*A. J. P.*, 1872, 559.)

Quinoline. *Chinoline. Leucoline. Chinolin,* G. $(C_9H_7N.)$—This is a tertiary base, resembling an alkaloid, found in coal tar. It may be prepared by the destructive distillation of quinine or cinchonine with potassium hydroxide, and also synthetically by König's and Skraup's processes by the action of sulphuric acid and glycerin upon nitrobenzene and aniline, or a mixture of these two latter substances. *Chinoline* is a colorless, strongly refractive, oily liquid, having a specific gravity of 1.094, boiling at 238° C., without decomposition, the oily stain left on bibulous paper disappearing readily on exposure. Its odor is aromatic, resembling that of oil of bitter almond. It is sparingly soluble in cold water, more so in hot water, soluble in alcohol, and mixes in all proportions with ether, carbon disulphide, methyl alcohol, etc. It easily dissolves camphor and resin. It gradually turns reddish-brown in color on exposure to the air. It forms readily crystallizable salts with acids, the tartrate now being a commercial article; these salts are decomposed by contact with fixed alkalies and the peculiar odor of quinoline developed. A number of compounds and derivatives are known among which are the following: *Quinoline tartrate,* $(C_9H_7N)_3.(C_4H_6O_6)_4$, is in the form of a whitish, micaceous, crystalline powder, melting at 125° C. It dissolves in 80 parts of cold water, in about 150 parts of alcohol, and in 300 parts of ether, having a peculiar pungent odor and a rather sharp, though not unpleasant taste. *Quinoline hydrochloride,* $C_9H_7N.HCl$, melts at 94° C. and sublimes unchanged. It dissolves in water, alcohol, and chloroform. *Quinoline salicylate,* $C_9H_7N.C_7H_6O_3$, is a white crystalline powder, soluble in water and glycerin, very soluble in alcohol, ether, vaseline, and fatty oils. (See also *Crurin.*)

While quinoline was originally brought forward as a substitute for quinine, experience has shown that it possesses only feeble antiperiodic properties. It is, however, an active antipyretic and is also a powerful germicide. It is a depressant to the central nervous system and in 1 per cent. solution will prevent the coagulation of the blood. It is used chiefly as an antiseptic, especially in the treatment of *gonorrhea* for which purpose an 0.7 per cent. solution may be employed. Quinoline has been highly commended as a preservative for anatomical specimens. For physiological study of quinoline derivatives see *Trans. College of Physicians of Edinburgh* (*Laboratory*). 1893; also Laidlaw (*Biochem. J.*, 1910, v, 243).

Quinotoxin. *Chinotoxin.*—This name was originally applied by Ostermayer to the *diquinolindimethyl sulphate,* a synthetic compound possessing toxic properties similar to those of curare. The term was afterwards applied to the decomposition product resulting from the action of acetyl-salicylic acid upon quinine. According, however, to Sollmann (*J. A. M. A.*, 1921, lxxvi, p. 999) this latter product is the same as quinicine and is of very low toxicity.

Quisqualis.—The seeds of the *Quisqualis indica* L. (Fam. *Combretaceæ*) (*Rangoon Creeper*) have been used as an anthelmintic and occasionally substituted for santonica. According to Davenport (*Schweitz. Apoth. Zeit.*, 1918, lvi, 522) they contain an active principle resembling santonin. The *dose* of the seeds is 7.5 Gm. (2 drachms).

Radium. Ra = 226.4.—*Radium* is an elemental substance, possessing remarkable chemical and physical properties, discovered in pitchblende, a complex uranium ore, by Professor and Madame Curie of the University of Paris, in 1900. It belongs below barium in the periodic system and on the same line with thorium and uranium, these three elements having the highest atomic weights of any known. The discovery that certain substances are radio-active was made by Henri Becquerel in 1896, who showed that *uranium* was capable of affecting a photographic plate in the same way as light. Shortly after this, it was shown that a number of other substances were radio-active. The characteristics of radio-active bodies are four: (1) They affect photographic plates; (2) they produce phosphorescence in certain substances; (3) they cause the surrounding air to become a conductor of electricity; (4) they produce heat. In 1899 Madame Curie, while investigating the radio-activity of certain minerals, came to the conclusion that the uranium ore, known as *pitchblende,* from Joachimsthal in Austria, must contain some substance more actively radiant than uranium itself. This led her to the separation of the element radium, which showed two million (2,000,000) times as much activity as uranium.

After tedious and difficult experimentation involving the recrystallization, precipitation, and concentration of a ton of the ore down to a few decigrammes of purified product, a barium-like element was discovered which was many thousand times as active as uranium in its radio-activity, and which was therefore named radium by its discoverers. England manufactures some radium, the Cornish pitchblende being richer in radium than that from Joachimsthal. *Autunite* from Portugal and China and also *torbenite* contain traces of radium. At present the main radium supply of the world is from *carnotite* which is found in large quantities in Colorado. In testing specimens of unknown ores for radio-activity, the photographic plate is used and an exposure is made of the unopened plate with a small metal object placed between the ore sample and the plate. After leaving the objects in this relative position for twelve hours or more the plate is developed in the regular way and is examined for evidence of a photographic outline or image of the metal object. The extraction of radium salts from radium containing ores includes three stages. First the ores are roasted; the roasted ores are then treated with sulphuric and nitric acids which takes out the uranium compounds and leaves the radio-active metals behind as sulphates; the residue is then treated alternately with alkalies and acids and is finally separated by fractional precipitation as sulphate.

One ton of uranium residues furnishes from 17 to 22 pounds of radio-active barium residue, which upon final concentration yields a few drachms of radium bromide of high radio-active power. Some ores like autunite contain but two or three milligrammes of radium to the ton of original ore. The yield of pure radium bromide from a ton of pitchblende is about 0.25 Gm. The yield from carnotite is somewhat larger.

Radium in the elemental form has recently been prepared and observed. It is a brilliant white metal fusing at about 700° C. It is bivalent and closely allied to barium.

Properties.—Radium gives off three groups of rays, which are known by the first letters of the Greek alphabet, *alpha, beta,* and *gamma rays.* The alpha and beta rays are universally acknowledged to be material substances, while the gamma rays are by some considered waves of ether, and by others as electrons. Besides these, in solution radium liberates a gaseous element which is known as *emanation.* This gas is formed in the radium while in the dry state, but is completely absorbed, and only given off from solutions of salts of the metal. The most widely accepted theory concerning the origin of these rays is that of Rutherford. According to this, radio-activity is a sign of atomic destruction, particles of matter being given off, and the element being changed into another form of element with a lower molecular weight. Thus uranium gives off alpha particles, and the residue is *ionium;* this gives off alpha particles, the residue being radium. The decomposition of radium forms emanation, which in turn gives off alpha particles, forming a series of active deposits known as Radium A., Radium B., C., D., E., F. (Polonium), and eventually Radium G., which is by some believed to be identical with lead.

This spontaneous transformation of radium goes on at a constant rate, independent of the physical state or chemical combination of the element. The rate is such that nearly 2000 years will elapse before half of any given quantity will be changed. The following table showing the disintegration of products and the length of time required for disintegration of half of each substance is taken from the *N. N. R.*, 1924:

RADIUM AND ITS DISINTEGRATION PRODUCTS

Substance	Chemical Nature	Atomic Weight	Half Value Periods
Radium	Metal	226	1,780 yrs.
Radium emanation	Inert gas	222	3.85 days
Radium A	Solid non-metal identical with polonium	218	3.0 min.
Radium B	Identical with lead	214	26.7 min.
Radium C1	Identical with bismuth	214	19.5 min.
Radium C2	Identical with thalium	210	1.4 min.
Radium C′	Identical with polonium	214	10.6 sec.
Radium D	Identical with lead	210	15.8 yrs.
Radium E	Identical with bismuth	210	4.85 days
Radium F	Polonium	210	136 days

The alpha rays, which constitute about nine-tenths of the radiation of radium are positively charged electrons with a mass about four times that of hydrogen, moving with a velocity approximately one-tenth that of the light wave. By some they are supposed to be identical with the element *helium*, or rather to represent helium in the process of formation. Their power of penetration is relatively small. They can pass only through three inches of air, and are stopped by a heavy sheet of note-paper.

The beta rays are negatively charged electrons, and are by many believed to be identical with the cathode stream formed in a Crooke's tube. Their velocity is about equal to that of light, and their penetration is quite considerable, it requiring a sheet of lead one centimeter in thickness to certainly stop them. The beta rays travel in the opposite direction to the alpha rays and are deviable by a magnetic field which the alpha and gamma rays are not.

The gamma rays form less than one per cent. of the total radiation. Of their nature comparatively little is known. Their penetration is extraordinary, exceeding that of the X-ray. Because of the fact that they are not deflected by a magnetic field it was formerly believed that they were non-material, but the theory has been brought forward that they are discrete particles, electrically neutral.

Emanation (or *radon*) is constantly being formed in radium. It is absorbed by the salts of the metal when in a dry state, but is liberated when the salt is dissolved. It is a gaseous element, called *niton* which may be liquefied at a temperature of −150° C., and has an atomic weight of 222. When freshly liberated it is radio-active but becomes exhausted within a relatively short time, one-half of its power being dissipated within four days. Any substance exposed to emanation becomes temporarily radioactive. This is due to a deposit of the solid matter into which emanation is transferred after giving off its alpha rays.

The approximate estimate of the radio-active power in given substances can be reached by the degree of its influence upon photographic plates or the degree of fluorescence imparted to a platinocyanide screen but accurate measurements are based upon their ionizing power, that is, upon the degree of electrical conductivity they impart to the air. For this purpose, an apparatus known as the electroscope is employed. A *Curie* is the amount of emanation in equilibrium with one gramme of radium. A micro-curie is one-millionth of this and is equivalent to the amount of emanation in one milligramme of radium and equals 2700 "Maché units."

Besides the therapeutic uses of radium described below it is being much used in activating luminous paints for watch, clocks, etc.

It has been estimated that the total amount of radium separated and in use in 1921 was less than 100 Gms.

Most of the radium which is used therapeutically is in a more or less impure state, and it becomes necessary to have some knowledge of the radio-active power of any known specimen before it is used for medical purposes. Because of its affinity for oxygen, it is very difficult to prepare radium in the elemental state and it is therefore usually marketed in the form of one of its salts. Of these the *carbonate* $RaCO_3$, the *chloride* $RaCL_2$, and the *sulphate* $RaSO_4$ are most frequently employed. The salts sold under these names do not pretend to be pure salts of radium but are mixtures with the corresponding salts of barium. They are usually sold on the basis of their radium content as measured electroscopically. Manufacturers of radium generally supply with each sample of the metal, a statement of its power.

Therapeutic Uses.—The medical value of radium depends in the first place upon the destructive action of the rays upon the certain pathological tissues, and secondly upon the alterations in functions which are produced by the internal administration of emanation. The widest use of radium has been as a destructive agent in various types of *neoplasms.* For this purpose it is applied in various forms of containers, the most popular being a sealed glass tube, which is enclosed within a thin aluminum capsule to protect it from breaking.

The earliest investigations of the action of radium rays upon living protoplasm appear to be those of Schwarz (*A. G. P.*, 1903), who showed that when hen's eggs were exposed to the metal there was a decomposition of the lecithin within them. London (*B. K. W.*, xlii) found that rabbits kept for two weeks in a cage on top of which was placed 25 mgm. of radium lost their hair, the ears necrosed and the sexual organs degenerated; he believes that the emanations have no effect on fibroid tissue. The alpha rays have considerable germicidal action, as apparently does also emanation, but neither of these have any great penetrative power, so that the anti-bacterial effect of radium is not likely to prove of practical utility.

When applied to the skin, radium produces no immediate effect, but lesions appear after considerable periods of incubation, which may be as long as two weeks. If the dose has been small there is merely redness, but after longer exposure an ulcer is formed which heals very slowly. Although there is left behind, when these ulcers heal, a white supple cicatrix, destruction to the hair follicles, sweat and sebaceous glands may have been the result of the action of the rays upon the skin. It is possible, however, to profoundly influence the deeply lying structures with much less danger of causing dermatological injuries than with the X-rays. This can be accomplished by screening off the relatively superficially acting alpha and beta rays which allows the deeply penetrating gamma rays alone to act.

Radium has been largely used for the destruction of *malignant growths* and ulcers such as *carcinomata, sarcomata, rodent ulcers, epitheliomata*, and the like, especially in *cancer of the uterus*. While there is no doubt that it exercises a beneficial action there is a considerable difference of opinion as to its precise value, some authorities going so far as to rank it superior to surgical operations while others maintain that it is to be classed as a palliative rather than a curative. (For discussion of its value in uterine cancer see *J. A. M. A.*, 1921, lxxvii, 604, et seq.)

It is also of great service in the treatment of *menorrhagia* and *metrorrhagia*. The mode of its action in these cases is not definitely known; it has been suggested that it is due to its effects upon the ovaries but Maury (*J. A. M. A.*, 1920, lxxiv, 1711) from experiments upon the lower animals concluded that its action was upon the mucous membrane of the uterus. Levin (*J. A. M. A.*, 1921, lxxvii, 930) has used it with asserted good results in *Hodgkin's disease* and in *lymphatic leukemia*.

The dosage of radium is generally expressed in terms of pure radium and time. For instance, if the quantity of the salts equivalent to one milligramme of pure radium is to be applied for one hour, the dosage set is "one milligramme, hour." If an impure preparation is employed, as is usually the case, its activity must be calculated to that of pure radium. For instance, if the salt represent five-hundred-thousand units, it would require four milligrammes to exercise the same effect as one milligramme of pure radium.

Emanation when introduced into the system appears to have an influence upon the circulation, but especially upon metabolism. According to Theis and Bagg (*J. Bi. Chem.*, 1920, xli, 525) radium emanations cause a marked increase in the elimination of nitrogen. According to Loewi (*B. K. W.*, 1912, xlix, p. 198), the inhalation of emanation produces a contraction of the vessels of the lungs, and dilation of the vessels of the brain, with some tendency to lower the general blood pressure. The effect upon metabolism is shown in an increased elimination of uric acid. Although His (*B. K. W.*, xlviii, p. 197) found after the exhibition of radium marked diminution in the amount of uric acid in the blood, Fine and Chace (*J. P. Ex. T.*, 1914, vi, 219) could find no such change. Armstrong (*Practitioner*, 1912, lxxxviii, p. 156) and a number of German writers have described beneficial results from the drinking of water containing emanation, and also from the inhalation of the gas itself in *gout*.

While it seems evident that radium emanation has some marked effect on metabolism the precise nature of this alteration remains as yet obscure. Clinically, radium has been used internally in the treatment of *gout, arthritis deformans* and other diseases of the joints; in muscular *rheumatism*, in *sciatica, neuralgia* and other painful conditions. Some believe that the beneficial effects obtained by drinking mineral waters is due to their radium content; but while it is a fact that many of the famed medicinal springs are radio-active it remains to be shown that this explains their beneficial action. Indeed, the whole use of radium as an internal remedy is still in the experimental stage. (For a list of some of the proprietary radium specialties see *A. Ph. A. Year-book of Pharmacy*, 1912, p. 302.)

Raisins. *Uva Passa. U. S.* 1870.—The dried ripe fruit of the *Vitis vinifera* L. (Fam. *Vitaceæ*), is no longer recognized by the Pharmacopœia. The grape vine itself is too well known to require description. The plant is a native of the southern shores of the Caspian Sea and Armenia, and has been cultivated in Europe and Northern Africa from the remotest antiquity, and is now spread over all the temperate civilized regions of the globe. Its leaves and tendrils are somewhat astringent, and were formerly used in *diarrhea, hemorrhages*, and other morbid discharges. The juice which flows from the stem was also thought to be possessed of medicinal virtues, and the idea still lingers among the vulgar in some countries. The unripe fruit has a harsh, sour taste, and yields by expression a very acid liquor, called *ver-juice*, which was much esteemed by the ancients as a refreshing drink when diluted with water. It contains malic and tartaric acids, and an acid called *racemic acid*, a compound isomeric with tartaric acid, but differing from it in being optically inactive. M. A. Petit has ascertained that grape leaves contain both glucose and sucrose, as well as tartaric acid. (*J. P. C.*, 1874.) The seeds afford from 15 to 18 per cent. of a bland fixed oil, which is occasionally extracted, and from 5 to 6 per cent. of tannic acid, which also exists in the skin of the fruit. The grape, when ripe, is among the most pleasant and grateful fruits, and is admirably adapted, by its refreshing properties, to febrile complaints. If largely taken, it proves diuretic and gently laxative. The ripe fruit differs from the unripe in containing more sugar and less acid, though never entirely destitute of the latter. The fruit is exceedingly influenced by soil and climate, and the varieties of the plant which have resulted from culture or situation are innumerable.

Several varieties of raisins are known in commerce. The best of the European fruit are the

Malaga raisins, imported from Spain. They are large and fleshy, of a purplish-brown color and sweet, agreeable taste. Those produced in Calabria are similar. The *Smyrna raisins* are also large, but of a yellowish-brown color, slightly musky odor, and less agreeable flavor. They are originally brought from the coast of Syria. The *Corinthian raisins*, or *currants* as they are commonly called in this country, are small, bluish-black, with a vinous odor and a sweet, slightly acid taste. Their name is derived from the city in the vicinity of which they were formerly cultivated. At present they are procured chiefly from Zante, Cephalonia, and the other Ionian Islands. In the older Pharmacopœias they are distinguished by the title of *uvæ passæ minores.* Within recent years the production of raisins in California has become an industry of the highest importance. These raisins are coming into large use in the United States and have largely replaced those obtained from Europe. The ripe grapes are cut from the vines, spread out on a clay floor, and dried by exposure to the heat of the sun. The drying process usually requires about ten days' time. Artificial heat is used to dry them in rainy weather; sometimes the grapes are partially dried on the vines; this is done by cutting the stalks of the ripe grapes half way through, and allowing the bunches to remain for a few weeks, a portion of the bark of the vine being removed also to facilitate the process. If it is desirable to remove the waxy bloom on the grapes, the bunches are steeped for a short time in weak alkaline solution, washed and then thoroughly dried.

Raisins usually contain more sugar than do fresh grapes. It is often so abundant that it effloresces on the surface or concretes in separate masses within the substance of the raisin. The average composition of raisins is, in parts per hundred: moisture 18.61, protein 3.09, fat 2.86, sugars 70.49, ash 2.70. The *sugar of grapes* (*dextrose*) differs from that of the cane, being less sweet, less soluble in cold water and much less so in alcohol. In these respects it does not differ from artificial dextrose, which is now made in enormous quantities and consumed in food products and candies; the artificial product is made by acting on starch with hydrochloric acid (see *Glucosum*).

The chief medicinal use of raisins is to flavor demulcent beverages. Taken in substance they are gently laxative, but are also difficult of digestion, and, when largely eaten, sometimes produce unpleasant effects, especially in children.

Radish. *Raphanus sativus* L.—The juice of this well known plant has been used by Grumme in the treatment of *cholelithiasis* as an aid in preventing the formation of biliary calculi. He employed the expressed juice of the crushed bulbs in *doses* of two to four fluidounces (60–120 cc.).

Saki reports the presence of an amylolytic enzyme in radish juice. (*J. P. C.*, 1906, 561.)

Sacher recommends the coloring matter from red radishes as a sensitive indicator in alkalimetry; the fresh peels are treated with alcohol and the solution is turned red with acids and green by alkalies.

Randia. *Randia dumetorum* Lam. (Fam. *Rubiaceæ.*)—The fruit of this spiny Asiatic shrub is used by the natives as a fish poison, and is said to act in man as an irritating emetic. According to the *Pharmacographia Indica*, each fruit contains about four grains (0.26 Gm.) of a saponin, besides valeric acid. The tincture has been used by James Sawyer (*L. L.*, 1891) as an antispasmodic.

Ranunculus. *Crowfoot. Renoncule*, Fr. *Hahnenfuss*, G.—Most of the plants belonging to the genus *Ranunculus* have similar acrid properties, and, from their close resemblance, are confounded under the common name of *buttercup. R. bulbosus* L. was formerly in the Secondary List of the U. S. Pharmacopœia; but *R. sceleratus* L. had attracted more attention in Europe, and *R. acris* L. and *R. flammula* L. were recognized by the Dublin College. In all these species the plant itself is a violent irritant, producing when chewed excessive inflammation in the mouth and throat, and, when swallowed toxic gastritis which may be fatal. Clarus discovered, in *R. sceleratus* L., besides an acrid volatile oil, a nearly inert resin, and *anemone camphor* (see under *Pulsatilla*). The volatile oil is soluble in ether, and is decomposed, on standing, into a white amorphous substance having acrid properties (*anemonic acid*), $C_{15}H_{14}O_7$. (*Brit. and For. Med.-Chir. Rev.*, 1859, 181.) Rochebrune states that he has separated from *R. aquatilis* L., *R. flammula* L., *R. sceleratus* L. and *R. bulbosus* L., crystalline alkaloids to which he has given the name of *ranunculine*, although their identity is doubtful. These alkaloids are violent irritants and active cardiac poisons. (*Toxicolog. Africaine*, i.) Before the introduction of cantharides the green butter-cup plants were much employed as vesicants.

Realgar. As_2S_2. *Red Orpiment.*—This is *arsenic disulphide.* It is found native in Saxony, Bohemia, Transylvania, and in various volcanic regions. *Realgar* is artificially made by melting arsenic trioxide with about half its weight of sulphur. Thus prepared, it is of a crystalline texture, of a beautiful ruby-red color, of a uniform conchoidal fracture, somewhat transparent in thin layers, and capable of being sublimed without change. Native realgar is said to be innocuous when taken internally, while that artificially prepared is poisonous, in consequence, according to Guibourt, of containing a little free arsenic trioxide. Realgar is used only as a pigment.

Red Chalk. *Reddle.*—A mineral substance of a deep red color, of a compact texture, dry to the touch, adhering to the tongue, about as hard as chalk, soiling the fingers when handled, and leaving a red mark when drawn over paper. It consists of clay and ferric oxide, and is intermediate between *bole* and *red ochre*, containing more ferric oxide than the former and less than the latter. It is used for drawing lines upon wood, etc., and is sometimes made into crayons by levigating and elutriating it, then forming it into a paste with mucilage of gum arabic, molding this into cylinders, and drying it. It has been used internally as an absorbent and astringent.

Resaldol. *Resoldol. Resorcin-benzoyl-carbonic acid-ethyl-ester.* $C_{20}H_{14}O_5(CH_3CO)_2$.—Resaldol is made by acetylating the product of the reaction between chlormethyl-salicylic aldehyde and resorcinol. It is an amorphous yellowish-brown powder of an astringent taste, insoluble in water and dilute acids, but soluble in alkalies. According to Impens (*D. M. W.*, 1913, p. 1827), it acts much like cotoin (see *Coto*), over which it has the advantages of being tasteless and nonirritant. It is used in *tuberculous* and other forms of *enteritis*. The *dose* is eight grains (0.5 Gm.) several times a day.

Reseda. *Reseda Luteola* L. *Weld. Dyer's Weed. Herbe Jaune, Gaude,* Fr. *Wau, Gelbkraut, Harnkraut,* G. (Fam. *Resedaceæ.*)—An annual European plant, naturalized on roadsides and ballast from Massachusetts to Pennsylvania. The plant grows to a height of 6 dm., possesses alternate lanceolate leaves and small greenish-yellow flowers. It is inodorous, and has a bitter taste, which is very persistent. Volhard showed that allyl thiocyanate, $C_3H_5.SCN$ (volatile oil of mustard), was present in the root, and Chevereul obtained from it by sublimation a peculiar yellow coloring matter, which he called *luteolin.* Hlasiwetz and Pfaundler (1895) assign to it the formula $C_{15}H_{10}O_62H_2O$ and find it to be tetrahydroxyflavone. This forms yellow crystals of silky luster, insoluble in water, soluble in alcohol. It dissolves in alkalies with deep yellow color. It is used especially in silk dyeing. A. G. Perkin (*J. Chem. S.*, 1896) investigated the salts of luteolin, and called attention to the similarity of its properties to those of fisetin (see *Fustic*). In medicine it has been employed as a diaphoretic and diuretic, but it is now used only for dyeing purposes.

Resineon.—This is a volatile oil obtained from black tar oil by distillation and stated to be free of phenol. It boils at 148° C. and is used externally as a dressing for wounds and injuries and as an antiseptic in *skin affections.* A 1 to 8 ointment is applied by inunction in *chronic eczema.*

Resorbin.—An ointment vehicle made by emulsifying almond oil and water by means of a little yellow wax, gelatin, and soap, to which is added some lanolin. It is asserted that it greatly facilitates the absorption of medicaments.

Resorcin Acetate. *Resorcinol Monoacetate, N. N. R.*, 1925.—This is a thick, yellow liquid, sparingly soluble in water but more soluble in alcohol and the organic solvents. It has a faint odor and a sharp taste. Its boiling point is 283° C.

Resorcin acetate is used in the treatment of skin diseases, such as *acne, chilblains, seborrhea,* etc. Its action is said to resemble that of resorcin but to be milder and more lasting.

Retinol. *Codoil. Rosinol. Rosin Oil.* $C_{32}H_{16}$.—A product obtained by the distillation of rosin. It forms a yellowish oil boiling at temperatures over 280° C. It is stated that *retinol* does not irritate the skin, is unaltered by light, is mildly antiseptic, does not become rancid, and is very inexpensive; qualities which, taken along with its extraordinary solvent power, bid fair to make it a valuable vehicle for ointments. Among the substances dissolved by it are: salol, 1–10; iodol, 1–50; naphthol, 1–50; thymol iodide, 1–50; camphor, 1–20; chrysophanic acid, 1–40; cocaine, 1–30; codeine, 1–40; and strychnine, 1–40. It is miscible in all proportions with oil of juniper, phenol, terpentine, alcohol, and ether. Resorcinol, if dissolved in glycerin, may be mixed with retinol, and so may iodoform if it be dissolved in a little ether. Iodol is dissolved, but soon precipitates as a resinous mass. Phosphorus is also dissolved, and the solution remains unchanged indefinitely. Retinol mixes readily with fats, oils, vaseline, lard, lanolin, glycerin, cacao butter, etc, and may be used in ointments. In cases where a liquid is not undesirable, retinol, owing to its antiseptic properties, can with great advantage replace these bodies. Upon the mucous membrane retinol seems to act as a mild stimulant antiseptic; it has been used with alleged excellent results locally in *otitis, vaginitis, rhinitis* and other mucous diseases. Injections of it in *gonorrhea* are said to be remarkably effective. As a means of administering phosphorus it is especially recommended.

Rhigolene.—This name was given by H. J. Bigelow of Boston, to a very light, inflammable liquid, obtained by distilling petroleum, and separating the liquids of the lowest boiling point by redistillation, until one is obtained which boils at about 18° C. It was used for producing local anesthesia by its rapid evaporation when sprayed upon the part, but has been displaced by ethyl chloride. The vapor is inflammable and care should be exercised in using it near a flame.

Rhizophora Mangle L.—This is a tree with coriaceous, elliptic to elliptic-ovate leaves and large yellow flowers belonging to the *Rhizophoraceæ* and forming thickets along the coast of Florida and in the tropics. The red bark of the *mangrove tree* has been used for many years by the natives of South America as a febrifuge. Duque and Moreno (*S. M.*, 1905, p. 479) have claimed that it is a specific in *leprosy.* They administer a beginning *dose* of one fluidrachm (3.75 cc.) of the fluidextract twice a day which is gradually increased until the patient is taking a fluidounce and a half (45 cc.) daily.

Rhododendron. *Rhododendron Chrysanthemum* Pall. *Yellow-flowered Rhododendron. Rosebay. Snowrose. Rosage,* Fr. *Alpenrose, Schneerose, Gichtrose,* G. (Fam. *Ericaceæ.*)—The leaves of this rhododendron have long been employed in Siberia as a remedy in *rheumatism,* and to a less extent in *gout* and *syphilis.* They yield their virtue to water and alcohol, and, according to von Archangelski, contain three proximate principles; *rhododendrol,* $C_{10}H_{12}O_2$; *rhododendrin,* $C_{16}H_{22}O_7$; and a glucoside resembling digitalin and very toxic. The *dose* of the dried leaves is said to be two drachms (7.7 Gm.), given in infusion. There have been several reports of sheep being poisoned through eating rhododendron leaves. De Zaayer found in *R. ponticum* the neutral principle, andromedotoxin. Hardikar (*J. P. Ex. T.*, 1922, xx, p. 17) confirms its presence in an unnamed species of rhododendron which he investigated, and made a careful study of its physiological action. (See *Andromeda.*)

G. F. Kuehnel found in leaves of the "great laurel," *Rhododendron maximum* L., a common shrub in the Alleghenies from New York to Georgia, arbutin, ericolin, and ursone. (*A. J. P.*, 1885.)

Rhus.—The genus *Rhus* contains various species which have the property of so violently irritating susceptible skins as to produce severe dermatitis. Of these poisonous species there are six which are indigenous to the United States.

R. vernix L. (*R. venenata* DC.)—*Swamp Sumac, Poison Sumach, Poison Elder* is our most poisonous species. It is a handsome shrub or small tree, usually ten or fifteen feet high. The bark of the trunk is dark gray, of the branches lighter. A prominent characteristic is the color of the extreme twigs and petioles, which is pale to deep red. The leaves are pinnate, with three to six pairs of opposite leaflets, and an odd terminal one. These are oblong or oval, entire or slightly sinuate, acuminate, smooth, and, except the one at the end, nearly sessile. The flowers are polygamous, very small, greenish, and in loose or slender axillary panicles. The berries are small, roundish, and greenish white. The tree grows in swamps and low grounds from Canada to Carolina, and flowers in June and July. It was confounded by the older botanists with *R. vernicifera* DC., of Japan, the Japanese lacquer tree, which has similar poisonous properties. Its activity is said to depend upon *urushic acid.*

Rhus Michauxii Sargent (*R. pumila* Michx.) is a rare Southern species, growing in upper Carolina and Georgia, and not more than a foot in height. It is characterized by its pubescent branches and petioles, by its pinnate leaves, with many pairs of oval, nearly acuminate, incised-dentate leaflets, downy beneath, and by its silky fruit. According to Pursh, it is the most poisonous of the genus.

Rhus diversiloba Torrey and Gray (*R. lobata* Hooker) is found on our Pacific border. It is there generally known as *Poison Oak,* and closely resembles *R. Toxicodendron* L.

Rhus Metopium L. (*Metopium Linnæa,* Engelm.), *Mountain Manchineel, Coral Sumac,* is a West Indian species, growing also in the "hummock" lands of Southern Florida. It is a small tree, the bark, when wounded, exuding a gum-resin to which medicinal properties are ascribed. This is known locally as *hog-gum,* but should not be confounded with the Asiatic *Hog-gum* or *Bassora.* The leaves are pinnate with fine leaflets. To the acid red fruit is due the name Coral Sumac. It is exceedingly poisonous.

Rhus Toxicodendron L. (*R. radicans* L.), *Poison Oak, Poison Ivy,* whose fresh leaves were formerly official in the U. S. Pharmacopœia under the name of *Rhus Toxicodendron,* U. S. 1890, is a woody vine climbing by numerous aerial rootlets to considerable heights and showing considerable variation. The leaves are 3-foliate, the leaflets being ovate or rhombic, 2.5 to 15 cm. long, entire or sparingly dentate or sinuate, acute or short-acuminate, the lateral sessile or short-stalked, are inequilateral, the terminal ones stalked. The flowers are green, 3 mm. broad, in loose axillary panicles, 2 to 8 cm. long; the fruit globose-oblong, whitish or cream colored, resembling that of *R. Vernix.*

The milky juice, of the poisonous species of *Rhus,* becomes black on exposure to the air, and leaves upon linen or other cloth a stain, which cannot afterwards be removed by washing with soap and water, or by alcohol either hot or cold, but deepens by age. It has been proposed as an indelible ink. Ether dissolves it; applied to the skin it frequently causes inflammation and vesication

The toxic principle of poison sumacs is generally believed to be *toxicodendrol,* an acid resin, but McNair concludes that it is a polyhydric phenol which he calls *lobinol* (*J. Am. C. S.,* 1921, xliii, 159). As toxicodendrol is non-volatile many have hesitated to accept it as the sole active principle because of the well-known fact that susceptible persons may be poisoned without actual contact with the plant, but Youngken and Slothower (*A. J. P.,* 1920, xcii, 695) have shown that the hairs on the leaves of the poison ivy contain the toxic principle. The latter may be carried by air currents or may be transported on clothes, or tools, or animals, which after brushing against the plant are able to transfer the poison to susceptible persons.

In the treatment of *ivy poisoning* a great variety of remedies have been lauded as specifics; among these may be mentioned fluidextract of grindelia, solution of lead subacetate, solution of formaldehyde, zinc sulphate, potassium permanganate, etc. Perhaps as successful treatment as any is to remove the poison from the skin with alcohol—it is not sufficient simply to bathe the part with alcohol as this serves only to spread the poison, it must be thoroughly washed. Afterwards apply a lotion of sodium thiosulphate of about 10 per cent. strength to which may be added one or two per cent. of phenol to allay itching. Thorough washing with soap—if due precaution against the transference of the poison to other parts of the body is observed—is probably also a valuable means of removing the poison; indeed it has been recommended that a thick lather of laundry soap be allowed to dry on the inflamed part as a curative. Schamberg (*J. A. M. A.,* 1919, lxxiii, 1213) succeeded in desensitizing persons against ivy poisoning by the use of ascending doses of a tincture of the drug by the mouth, and Strickler (*J. A. M. A.,* 1923, lxxx, 1588) has employed hypodermic injections of an extract as a curative. Warren (*A. J. P.,* 1913, p. 548) was unable to detect a poisonous principle in the pollen grains of *Rhus Vernix.* See also Tschirch and Stevens, *A. J. P.,* 1906, p. 63. Besides the poisonous principle of rhus there is present an iron greening tannin, chlorophyll, wax, fixed oil, resin, sugar, albumen, pectin, gum, starch, and oxalic acid.

The poisonous rhus when taken internally appears to be possessed of narcotic besides irritant properties, vomiting, drowsiness, stupor, dilated pupils, convulsive movements, delirium, and fever having been present in poisoning by them. The tincture of rhus has been used by homeopathic practitioners in the treatment of *subacute* and *chronic rheumatism,* and the practice has found imitation. Some years ago H. C. Wood made extended trials of the remedy, using a homeopathic tincture obtained from a homeopathic pharmacy, in various doses (homeopathic, small, and large), upon a large number of cases of various types of rheumatism, in the Philadelphia Hospital, but he was not able to perceive that the patients progressed more rapidly when taking it than when they were simply nursed.

Rhus canadensis Marsh. (*R. aromatica* Ait) (Fam. *Anacardiaceæ*).—This indigenous shrub, growing in dry soil from Maine and Southern Ontario to Florida and westward, has been highly recommended in the treatment of *nocturnal incontinence* of urine by a number of clinicians of repute (See *G. H. M. C.,* 1889; also *Annals of Gynæc.,* 1890.) The adult *dose* is twenty or thirty minims (1.3–1.8 cc.) of the fluidextract of the bark, three times a day, given in aromatized solutions.

Ricin is the name given by Kobert and Stillmark to the toxic constituent of castor beans (*Ricinus communis* L.). It belongs to the class of albuminoids and is of the character of an enzyme. It is a white powder which forms a turbid liquid in a 1 per cent. solution of sodium chloride. It has been proposed by Jacoby to detect the presence of pepsin in liquids by using *ricin.* (*M. R.,* 1907.) For a valuable paper by Finnemore and Deane read before the British Pharmaceutical Conference, 1905, see *M. R.*, 1906, 165. The toxic symptoms, which frequently do not come on for several hours after the ingestion of the poison, are due primarily to the intensely irritant action of the substance, and consist of diarrhea, with suppression of the urine, and frequently jaundice, probably from irritation of the mucous membrane of the biliary ducts. Müller (*A. E. P. P.*, 1899, xlii) states that the poison also has a direct action upon the medulla, leading to the fall of blood pressure and lessened respiratory activity.

The effects of ricin in many directions bear a striking resemblance to the effects of bacterial toxins. Thus, for example, it produces a leucocytosis and an agglutination of the red corpuscles. The most interesting, however, of these resemblances is the production of immunity and the formation of antitoxic substances.

Rimu Resin.—The resin of the *Dacrydium cupressinum* Solander, the New Zealand red pine or *rimu*, a large coniferous tree of New Zealand, is characterized by its rose color and its crystalline appearance. It is composed chiefly of a crystalline acid resin, *rimuic acid.* (*Chem. News*, lxxxviii, 20.)

Ristin.—This is the mono-benzol ester of ethylene glycol. It is marketed only in the form of a 25 per cent. alcoholic solution. The latter is asserted to possess antiseptic properties and is used in the treatment of *scabies* mixed with equal parts of glycerin.

Robinia. *Robinia Pseudo-Acacia* L. *Black Locust Tree. Yellow Locust. False Acacia. Robinier*, Fr. *Falsche Akasie*, G. (Fam. *Leguminosæ.*)—This well-known indigenous tree has a place in the materia medica of the eclectics. The root and inner bark are poisonous but the leaves are said to offer a wholesome food for foraging animals. This would seem confirmed by the experiment of Paven, who failed to find in them any poisonous principles. Kobert (*M. Bull.*, April, 1891) found in the bark an albumoid enzyme, which he named *robinalbin*, similar to, but not identical with, ricin. Power (*P. J.*, Aug. 17, 1901; *A. J. P.*, 1913, 339) summarizes the results of a more detailed investigation of this bark. He names the poisonous proteid *robin* and states that it belongs to the class of nucleoproteids. He finds evidences of one or more alkaloids; by hydrolysis he obtained *syringic acid*, $C_9H_{10}O_5$, and a red amorphous substance, *syringenin.* These products indicate the glucoside *syringin*, $C_{17}H_{24}O_9$. He also considers that *glucosyringic acid*, $C_{15}H_{20}O_{10}$, may pre-exist in the bark. In the bark of the locust tree grown in Japan Tasaki and Tanaka (*J. Soc. Chem. Ind.*, 1919, xxviii, 267) found a poisonous glucoside, *robitin.* The most striking toxic effects of this were fever and paralysis of the hind legs. Robin has emetic and purgative properties. Z. T. Emery (*N. Y. M. J.*, Jan. 22, 1887) reports the poisoning of thirty-two boys from chewing the inner bark of the tree. The symptoms in the mildest cases were vomiting and flushed face, dryness of the throat and mouth, and dilated pupils. In the severest cases, to these were added epigastric pain, extremely feeble, intermittent heart action, and stupor. The air dried seeds have been examined by van Berk (*Pharm. Weekblad.*, 1917, liv, 1278.) and found to contain, water 13 per cent., fat 8.5 per cent., albumin 38 per cent., soluble carbohydrates 18 per cent. Feeding experiments showed the seeds to be harmless to animals.

Robinia Nicou Aubl., now known as *Lonchocarpus Rufescens* Benth.—According to the researches of Geoffroy (*Annal. de l'Inst. botanico-geologique colon. de Marseille*, 1895), this leguminous plant, which is used in Guiana for the purpose of stupefying fish, contains an active principle, *nicoline* (C_3H_4O), which crystallizes in oblique, rhomboidal tables. It has been found by E. Boinet (*C. R. S. B.*, 1886, 10 s., iii) to produce in the lower animals a short primary stage of excitation, followed by one of stupor, great muscular relaxation, enfeeblement of sensibility, mydriasis, fall of temperature, cyanosis, and death through centric paralysis of the respiration, though there is also fall of arterial pressure. In the dog there was salivation and vomiting.

Rosa.—Of the genus *rosa* at least four species have been, and probably to some extent are still, used in medicine—namely, *Rosa canina* L., *Rosa centifolia* L., *Rosa damascena* Mill., and *Rosa gallica* L.

Rosa canina.—The *Dog Rose, Wild Brier*, or *Hip Tree*, of Europe, North Africa and West Asia is an upright shrub characterized by having branches with stout hooked prickles, imparipinnate leaves with 5–7 oval or elliptic, doubly serrate leaflets and light pink flowers with usually 5 obcordate fragrant petals. The fruit consists of a fleshy, hollow receptacle, bearing on its inner surface a number of hairy achenes. The ripe fruit, which is usually employed in the fresh condition, is ovoid, smooth, shiny and red in color. Rose hips possess a pleasant, sweet, acidulous taste. It was formerly official in the British Pharmacopœia under the name of *Rosæ Caninæ Fructus.* It contains about 30 per cent. of sugar, combined with citric and malic acids, also salts of these acids, and a trace of tannin. A confection is sometimes used as a pill excipient. Vanillin has also been found present in the petals.

Rosa centifolia, the *Cabbage Rose* or *Pale Rose*, has prickly stems and the leaves consist of two or three pairs of leaflets, with an odd one at the summit closely attached to the common footstalk, which is rough, but without spines. The leaflets are ovate, broad, serrate, pointed, and hairy on the under surface. The flowers are large, with many petals, generally of a pale red color, and supported upon peduncles beset with short bristly hairs. The varieties of *R. centifolia*, produced by its almost universal cultivation, are very numerous, but the plant is said to grow with single flowers in its native home, which is the eastern part of the Caucasus. It is very closely allied to *R. gallica*, Regel considering it a variety of *R. gallica.* The petals, which were recognized by the U. S. P., 1890, as *pale rose*, are roundish-obovate and retuse, or obcordate, pink, fragrant, sweetish, slightly bitter, and faintly astringent. They contain volatile oil, malic and tartaric acids, tannin, fat, resin, sugar, and a coloring matter which seems to be identical with that of the red rose. They should be collected when the flower is fully expanded but has not begun to fall. Their fragrance is impaired but not lost by drying. They may be preserved for a considerable time by compressing them with alternate layers of common salt in a well-closed vessel, or beating them with twice their weight of that substance. A rose water is often prepared from them by distillation.

Rosa damascena or *Damask Rose* is not known in the wild state. It was introduced into Europe from Asia Minor in the 16th century. It is the rose which is cultivated mainly on the southern side of the Balkan mountains, in Bulgaria, and yields the commercial *otto of rose.* (See *Oleum Rosæ.*) It is a tall shrub with usually double, red, pink, white, or striped flowers of moderate size, having several on a branch, though not clustered. Its volatile oil is the base of rose water.

Rosemary. *Rosmarinus. Folia Rosmarini, s. Roris Marini. Folia Anthos. Feuilles de Romarin,* Fr. Cod. *Rosmarin, Rosmarinblätter,* G. *Rosmarino,* It. *Romero,* Sp.—"The leaves of *Rosmarinus officinalis* (Fam. *Labiatæ*)." *U. S.,* 1880. *Rosemary* is a small evergreen shrub, with an erect stem, divided into many long, slender, ash-colored branches. The leaves are numerous, sessile, opposite, about 2.5 cm. long, rigid, linear, entire, obtuse at the summit, folded backward at the edges, of a firm consistence, smooth and green on the upper surface, whitish, woolly, and glandular beneath. The flowers occur in pale blue verticillasters. The plant is native to the countries which border on the Mediterranean, and is cultivated in the gardens of Europe and the United States. The leaves, which have already been described, have a strong balsamic odor, which is possessed, but in a less degree, by all parts of the plant. Their taste is bitter and camphoraceous. These properties are imparted partially to water, completely to alcohol, and depend on the volatile oil. (See *Oleum Rosmarini,* Part I.) The present commercial supplies of this drug are from France. The tops lose a portion of their sensible properties by drying, and become inodorous by age. Rosemary is gently stimulant, and has been considered emmenagogue. In the practice of this country it is scarcely used; but in Europe, especially on the continent, it enters into the composition of several syrups, tinctures, etc., to which it imparts its agreeable odor and excitant property. It is sometimes added to sternutatory powders, and is used externally in connection with other aromatics in the form of fomentation. In some countries it is employed as a condiment; and its flowers, which are much sought after by the bees, impart their peculiar flavor to the honey of the districts in which the plant abounds.

Rotten Stone. *Terra Cariosa.*—An earthy mineral, occurring in light, dull, friable masses, dry to the touch, of a very fine grain, and of an ash-brown color. It is obtained from Derbyshire, in England, and is used for polishing metals. For a particular account of it, see *A. J. P.,* 1860, 463.

Rourea. *Rourea oblongifolia* Hook. and Arn. (Fam. *Connaraceæ.*)—This Mexican creeper is affirmed to contain an alkaloid, and to act as a violent convulsant poison. (*El Estudio,* 1890.)

Rubia. *Madder. Garance,* Fr. *Krappwurzel, Färberröthe,* G. *Robbia,* It. *Rubia de tintoreros, Granza,* Sp.—Under this name the U. S. P. 1870 recognized the root of *Rubia tinctorum* L. (Fam. *Rubiaceæ.*) The root of *dyer's madder* is perennial, and consists of numerous long, succulent fibers, varying in thickness from the size of a quill to that of the little finger, and uniting at the top in a common head, from which also proceed side-roots that run near the surface of the ground, and send up many annual stems. The quadrangular stems are furnished with short prickles by which they adhere to neighboring plants, upon which they climb. The leaves are arranged in whorls at the joints of the stem. The flowers are small, yellow and terminal. The plant is a native of Southern Europe. The root, which is dug up the third summer, enters commerce either in the form of the whole root deprived of its cuticle, or in the form of a reddish-brown powder.

Madder contains as its most important constituent *alizarin,* $C_{14}H_6(OH)_2O_2$, and with it as coloring matter of secondary importance *purpurin,* $C_{14}H_5(OH)_3O_2$. Besides these two technically important constituents there have been recognized *pseudopurpurin,* an orange dye color, and a yellow one (*xanthopurpurin*). These coloring matters, however, are probably decomposition products from glucosides existing in the fresh plant. Thus, alizarin is known to result along with glucose from the treatment with dilute acids of *rubianic* or *ruberythric acid,* $C_{26}H_{28}O_{14}$. The most interesting of the coloring substances is the *alizarin,* and this is now termed *dihydroxyanthraquinone,* $C_6H_4(CO)_2.C_6H_2(OH)_2$. This occurs as orange-red crystals, almost insoluble in cold water, but readily soluble in alcohol, ether, the fixed oils, and alkaline solutions. The alcoholic and aqueous solutions are rose-colored; the ethereal, golden yellow; the alkaline, violet and blue when concentrated, but violet-red when sufficiently diluted. A beautiful rose-colored lake is produced by precipitating the solution of alizarin with alum. Alizarin was recognized by Graebe and Liebermann in 1868 as a derivative of anthracene, $C_{14}H_{10}$, and elaborated a method for preparing it commercially from anthracene. Upon this arose rapidly a great chemical industry, and the cultivation of madder, has, of course, decreased correspondingly.

Madder when taken into the stomach imparts a red color to the milk and urine, and to the bones of animals, without sensibly affecting any other tissue. Under the impression that it might effect some change in the osseous system, it has been prescribed in *rachitis,* but without favorable result. It was also formerly used in *amenorrhea. Dose,* about half a drachm (2.0 Gm.), repeated three or four times a day.

Rubidium.—Rb–85.45. A soft silvery white metal belonging to the alkali metal group with potassium and sodium, easily oxidized in air, only stable when kept immersed under a hydrocarbon. Sp. gr. 1.532, melts at 39° C.; and boils at 696° C. Decomposes water when brought into contact with it, dissolved by acids to form salts. Salts of *rubidium* may be obtained much more cheaply than in former years, on account of Erdmann's process for the recovery of these salts from the Stassfurt potash deposits. Several salts have been brought forward for use in practical medicine.

Rubidium Carbonate. $RbCO_3.H_2O$.—A white powder, deliquescent and strongly caustic. Decomposes upon exposure to the air with the formation of rubidium bicarbonate ($RbHCO_3$) which is crystalline, permanent in air and with a faint alkaline reaction.

It is used in preparing salts of rubidium.

Rubidium iodide, RbI, which occurs in white lustrous crystals, or a white powder, freely soluble in water, has been recommended by Harnack, Neisser, and others as a substitute for potassium iodide, than which it is asserted to be better borne by the stomach. The dose is that of potassium iodide. G. Jacontini affirms that rubidium iodide is a specific in *coryza.* It has also been used as a substitute for the other iodides in *syphilis. Dose,* one to five grains (0.06–0.3 Gm.).

Rubidium bromide, RbBr, may be used as a substitute for, and in the dose of, potassium bromide, than which it is said to be better borne, especially by feeble patients.

Rubidium and Ammonium Bromide ($RbBr + 3NH_4Br$).—A white or slightly yellowish, crystalline powder, readily soluble in water. Its taste is somewhat cooling at first, and pungently saline afterwards. This salt, one hundred parts of which contain thirty-six parts of rubidium bromide and sixty-four of ammonium bromide (NH_4Br) is used as a sedative, similar in action to potassium bromide. *Dose,* from one to two drachms (3.9–7.7 Gm.) in a day.

Rubidium Sulphate. Rb_2SO_4.—This occurs as large, rhombic crystals with a taste resembling potassium sulphate. It is soluble in water and is stated to be a very active cathartic.

Rue.—*Ruta.* U. S. 1870. *Garten-Raute,* G.; *Ruda,* Sp. The U. S. P. formerly recognized the leaves of the *Ruta graveolens* L. (Fam. *Rutaceæ*). It is a low, shrubby plant, with several shrubby branching stems, which, near the base, are woody and covered with a rough bark, but in their ultimate ramifications are smooth, green, and herbaceous. The leaves are fleshy, 2- to 3-pinnatifid, the ultimate lobes or divisions being obovate-cuneate. The flowers are yellow, and disposed in a terminal branched cyme. The plant is a native of the south of Europe, locally established in pastures in the United States and cultivated in our gardens. The leaves have a strong, disagreeable odor, especially when rubbed. Their taste is bitter, hot, and acrid. When recent, and in full vigor, they have so much acrimony as to inflame and even blister the skin, if much handled; but the acrimony is diminished by drying. Their virtues depend chiefly on a volatile oil, which is contained in glandular vesicles, apparent over the whole surface of the plant. They contain, also, a peculiar acid, *rutinic acid,* $C_{27}H_{32}O_{16}$. Rutinic acid is the coloring principle of rue, and has been found in various other plants; though, like quercitrin, yielding quercetin and sugar, it has been shown to be distinct.

Rue yields a very small proportion of a yellow or greenish volatile oil (*Oleum Rutæ, U. S.,* 1880), which becomes brown with age. According to Zeller, the yield from the fresh herb is 0.28 per cent., that from the seeds about 1 per cent. The oil has the strong unpleasant odor of the plant, and an acrid taste. Kane gives its sp. gr. at 0.837, its boiling point at 230° C. "A neutral reaction. Sp. gr. about 0.880. It is soluble in an equal weight of alcohol." *U. S.,* 1880. It consists mainly of an oxidized constituent, which Strecker proved to be *methyl-nonyl-ketone,* $CH_3.CO.C_9H_{19}$. This accounts for its yielding under treatment with oxidizing agents, pelargonic acid, $C_9H_{18}O_2$. The methyl-nonyl-ketone, when pure, is a colorless liquid, fluorescing blue, boiling at 225° C., and crystallizing at about 15° C. Schimmel & Co. (*Schim. Rep.,* 1892, 31) state that pure oil of rue consists of 90 per cent. of methyl-nonyl-ketone, and solidifies even at a moderate temperature to a solid, crystalline mass, and has the sp. gr. 0.837.

According to von Soden and Henle, *Algerian oil of rue* differs from the ordinary oil in that it is chiefly composed of methyl-heptyl-ketone, with but small quantities of methyl-nonyl-ketone. Its specific gravity at 15° C. is 0.842; and it does not solidify at –15° C. (*Ph. Ztg.,* 46.) Power and Lees (*Trans. Chem. Soc.,* 1902) find in Algerian oil 80 per cent. of the two ketones, 10 per cent. of the corresponding carbinols (alcohols), pinene, l-limonene, cineol, methyl salicylate, ethyl valerate, and some free fatty acids.

Rue is said to have been used by the ancients as a condiment. In modern times it has been employed in *hysteria, worms, colic,* and atonic *amenorrhea* and *menorrhagia.* Its medicinal activity depends upon its volatile oil, which is a powerful local irritant, causing, when applied to the skin persistently, burning, redness, and vesication, and when taken internally in large doses, violent gastric pains and vomiting, great prostration, confusion of mind, convulsive twitching, and in pregnant women, abortion. It has been considerably used in Europe for the production of criminal abortion, in a number of cases with fatal results. The experiments of Prochnow (*A. I. P. T.,* 1911, xxi, 314) demonstrate, however, that it has only a feeble influence on the uterus. In a case of fatal poisoning in a man, reported by G. F. Cooper, there were vomiting, violent tormina and tenesmus, with bloody stools, great abdominal distention, with tenderness and severe strangury. (*Med. Exam.,* N. S., ix, 720.) The *dose* of the oil is from two to five minims (0.12–0.3 cc.) every two or three hours. The rue itself is sometimes given in the *dose* of from ten to thirty grains (0.65–2.0 Gm.).

Ruthenium. Ru–101.7.—A grayish black brittle metal. Sp. gr. 8.6, melting point about 2000° C. Soluble in aqua regia. This is one of the platinum group of rare metals. Several of its salts have been proposed for use in medicine or as reagents.

Ruthenium Chloride. *Ruthenium Sesquichloride.* Ru_2Cl_6.—A deliquescent, crystalline mass of a brownish-red color and soluble in water and stated to possess a high antiseptic value.

Ruthenium Red. *Ruthenium Oxychloride Ammoniated.* $Ru_2(OH)_2Cl_4.7(NH_3) + 3H_2O$.—A brownish-red powder, soluble in water. It is used as a microscopic stain and reagent for pectin, plant mucin, and gum. In bacteria staining there must be added to the *ruthenium red* a small amount of acetic acid.

Rye. *Secale cereale* L. (Fam. *Gramineæ.*) *Roggen,* G. *Leigle,* Fr. *Centeno,* Sp.—*Rye* is a tall annual cereal allied to wheat and barley. Its native country is somewhat doubtful, but is said to be found wild throughout the Mediterranean countries, extending to Central Asia. Hackel believes the species to have been derived from *Secale montanum* Guss., a wild perennial indigenous to the mountains of South Europe and Central Asia. There are two prominent varieties known as "Winter" and "Spring" rye, the difference being due to cultivation mainly. Rye is now cultivated in all temperate latitudes. The average composition of rye as a cereal may be thus stated: fat, 1.43 per cent.; starch, 61.87 per cent.; sugar (as sucrose), 4.30 per cent.; albumen (insoluble in alcohol), 9.78 per cent.; nitrogenous matter (soluble in alcohol), 5.09 per cent.; cellulose, 3.23 per cent.; mineral matter, 1.85 per cent.; moisture, 12.45 per cent. (Sadtler, *Industrial Organic Chemistry,* 3d ed., p. 169.) *Rye flour* is used, in the dry state, as an external application to *erysipelatous inflammation* and other eruptive affections, the burning and unpleasant tingling of which it tends to allay, while it absorbs the irritating secretions. In the form of mush it is an excellent laxative article of diet, and, mixed with molasses, it may be given with great advantage in *hemorrhoids* and *prolapsus ani,* connected with *constipation.*

Sabadilla. *Cevadilla.*—The dried ripe seeds of *Schoenocaulon officinale* (Schlecht.) A. Gray [*Asagræa officinalis* (Cham. and Schlecht.) Lindl.], were recognized by the Br. Pharm. of 1885. At one time cevadilla was generally believed to be derived from *Veratrum Sabadilla* Schiede. The plant grows in the Andes of Mexico and in the mountains of Guatemala and Venezuela. It is also cultivated. The fruit is a capsule having three locules in each of which there are from three to four seeds. A resemblance, existing or supposed, between this fruit and that of barley is said to have given rise to the Spanish name cevadilla, which is a diminutive of barley. The seeds are elongated, pointed at each end, flat on one side and convex on the other, somewhat curved, 5 to 8 mm. long, wrinkled, slightly winged, black or dark brown on the outside, whitish within, hard, inodorous, and of an exceedingly acrid, burning, and bitter taste. The powdered drug is sternutatory.

Cevadilla contains about 0.3 per cent. of alkaloids for account of which see under *Veratrina.*

Cevadilla is an acrid, drastic emeto-cathartic, operating occasionally with great violence, and in overdoses capable of producing fatal effects. Known in Europe as early as 1752, and formerly used to some extent as a tænicide, in *doses* of from five to twenty grains (0.32–1.3 Gm.), it was official solely as the source of veratrine. It is the principal ingredient of the *pulvis capucinorum,* sometimes used in Europe for the destruction of vermin in the hair.

Sabbatia. *American Centaury. Centaurée Américaine,* Fr. *Sabbatie,* G.—The overground plant of *Sabatia* (*Sabbatia*) *angularis* (L.) Pursh. (Fam. *Gentianaceæ*), an herb found in rich soil throughout the Eastern and Central United States and Ontario. The stems are much branched, distinctly 4-angled, and from 3 to 9 dm. high. The leaves are ovate, 5-nerved, having a heart-shaped clasping base. The flowers are rose-pink and on drying become pinkish brown. The fruit is a 2-valved capsule, dark brown and covered with a resin. It is more or less used in popular medicine as a tonic and antiperiodic. It is a simple bitter of some activity, and may very well be substituted for the foreign remedies of its class. Rodney H. True found American centaury adulterated with *Rhexia mariana* L., also known as *deer grass* or *meadow beauty.* (*A. J. P.,* 1905, 213.) John F. Huneker found in *sabbatia* a small proportion of *erythrocentaurin,* $C_{27}H_{24}O_8$, previously discovered by Méhu in *Erythræa Centaurium* Pers., of Europe.

In the southeastern United States, the *Sabbatia Elliottii* Steud., or *Quinine flower,* and in the southwestern United States the *Sabbatia campestris* Nutt. have been employed like the *S. Angularis* in the north. According to Merck the *S. Elliottii* contains a glucoside, *sabbatin,* as its active principle. Of the *S. angularis* and the *S. campestris* the whole plant is used, the *dose* being a drachm (3.9 Gm.), given in the form of fluidextract or in decoction. Of the quinine flower, the root is employed; *dose,* of the fluidextract, one fluidrachm (3.75 cc.); in intermittent fever to be repeated at short intervals.

Sabina. *U. S. VIII. Savin. Sabinæ Cacumina. Summitates* (*Herba*) *Sabinæ. Savine Tops. Sabine,* Fr. Cod. *Sadebaumspitzen. Sevenkraut,* G.—"The tops of *Juniperus Sabina* Linné (Fam. *Coniferæ*)." *U. S. VIII.* An evergreen, spreading or prostrate, rarely erect, shrub, with several varieties, from three to ten feet high, with numerous pliant branches. The leaves, which completely invest the younger branches, are numerous, small, firm, smooth, pointed, dark green, glandular in the middle, opposite, and imbricated in four rows. The fruit is a blackish-purple galbalus of globular shape, and containing three seeds. Although savin is a native of the mountains of Europe and West Asia, it grows wild in the neighborhood of the northwestern lakes of the United States.

The ends of the branches, and the leaves by which they are invested, are collected for medicinal use in the spring. They were officially described as "short, thin, subquadrangular branchlets bearing leaves which are rather dark green, in four rows, opposite, scale-like, ovate-lanceolate, more or less acute, appressed, imbricated, having on the back a shallow groove containing an oblong or roundish gland; odor peculiar, terebinthinate; taste disagreeable, resinous and bitter." *U. S. VIII.* They have a strong, heavy, disagreeable odor, and a bitter, acrid taste. These properties, which are less striking in the dried than in the recent leaves, are owing to a volatile oil.

In America the tops of *Juniperus virginiana* L., or common *red cedar,* also commonly referred to as *savin,* are sometimes substituted in commerce for savin, which they resemble closely, but from which they can be distinguished by some of their leaves being obtuse or acutish and the fruits being smaller, purplish and containing fewer seeds. In Europe savin is said to be adulterated with the tops of *J. phœnicea* L., which contain volatile oil similar to that of *J. communis* L. Such substitution is to be detected by the fact that in *J. phœnicea* the imbricated leaves occur in spirals of five, and the berries are large, shiny, and vary in color from yellow to reddish-yellow. In the mesophyll there occur large stone cells which are either single or in groups.

The proportion of volatile oil obtained from savin varies from 1 to 2.5 per cent. The *oil of savine* (*Oleum Sabinæ, U. S. VIII*) is "a colorless or yellowish liquid, having a peculiar terebinthinate odor, and a pungent, bitter, and camphoraceous taste. Specific gravity: 0.903 to 0.923 at 25° C. The oil is dextrogyrate, the angle of rotation varying between $+40°$ and $+60°$ in a 100 mm. tube, at a temperature of 25° C. Soluble in about one-half volume or more of 90 per cent. alcohol." *U. S. VIII.* According to Schimmel & Co. (*Schim. Rep.,* April, 1897), it contains pinene, $C_{10}H_{16}$, cadinene, $C_{15}H_{24}$, and an alcohol, $C_{10}H_{16}O$, *sabinol,* which is present both in the free state and as acetic ester. With iodine it becomes heated, detonates, and gives off yellow and violet-red vapors. (Flaschoff.)

Savin is highly irritant, and is supposed to have a special direction to the uterus. It has been much used in *amenorrhea* and *atonic menorrhagia,* and occasionally as a remedy for *worms.* Chapman strongly recommended it in *chronic rheumatism,* and it is employed in Germany, both internally and externally, in *chronic gout.* In overdoses it may produce dangerous gastro-intestinal inflammation, and it should therefore be used with caution. The oil of savin is a powerful local irritant, producing, when persistently applied to the skin or the mucous membrane, violent inflammation. It has been much used for the purpose of producing criminal abortion, and in a number of such cases has caused death, the symptoms being violent abdominal pain, bloody vomiting and purging, diminution or suppression of urine, disordered respiration, unconsciousness, convulsions, and fatal collapse. Although Prochnow (*A. I. P. T.*, 1911, xxi, p. 316) has found that small doses of savin have a slight stimulating effect upon the uterus, it is manifest that any abortifacient results must be due to general disturbance of the health rather than to any local action. The fluidextract which was official in the U. S. P. VIII, is rarely used internally but the stated *dose* is from five to ten minims (0.3–0.6 cc.). The *dose* of the oil of savin is from one to three minims (0.06–0.2 cc.).

Safrol. *Safrolum. U. S. VIII. Synthetic Oil of Sassafras.* $C_{10}H_{10}O_2 = 162.08$.—"The methylene ether of allyl pyrocatechol [$C_6H_3.C_3H_5.OOCH_2$) 1 : 3 : 4], found in oil of sassafras, camphor oil, and other volatile oils, purified, if necessary, by repeated chilling and crystallization." *U. S. VIII.* Safrol is found in oil of sassafras often in the proportion of 80 per cent., but commercially it is obtained from the red oil of camphor, by fractional distillation, the portion boiling at about 230° C. contains the safrol, this is cooled and the crystals separated.

Safrol appears to be widely distributed in the vegetable kingdom, probably existing in the bark of the *Mespilodaphne Sassafras* Meissn. in the *Sassafras nuts* (see *Pichurim Beans*, Part II), both of Brazil, in the bark of *Atherosperma moschatum* Labill. and in many other plants. It was officially described as "a colorless or faintly yellow liquid with a sassafras-like odor. Specific gravity: 1.098 to 1.100 at 25° C. Boiling point: about 233° C. It is optically inactive. On cooling to −20° C. or below, it solidifies to a mass of crystals, which do not melt below 11° C. Soluble in about an equal volume of strong alcohol, and in about 30 parts of 70 per cent. alcohol. Miscible in all proportions with ether and chloroform." *U. S. VIII.* Physiologically and therapeutically, safrol is equivalent to oil of sassafras. *Dose,* three to eight minims (0.2–0.5 cc.).

Sagapenum.—This gum-resin, formerly highly esteemed, but at present very rarely met with even in Eastern commerce, is the concrete juice of a Persian plant, *Ferula Persica* Willd. (Fam. *Umbelliferæ*), related to those that yield galbanum. It is in irregular masses, composed of agglutinated fragments, slightly translucent, of a brownish-yellow, olive, or reddish-yellow color externally, paler internally, brittle, of a consistence somewhat resembling that of wax, and often mixed with impurities, especially with seeds more or less entire. It has an alliaceous odor less disagreeable than that of asafetida, and a hot, nauseous, bitterish taste. According to Tschirch (*Harze und Harzbehälter,* 229), it contains 23.3 per cent. of gum; 19.2 per cent. of essential oil, containing sulphur; and 57.5 per cent. of a resin which is free from sulphur and melts at 74° to 76° C. The ether soluble resin of *sagapenum* can be separated by saponification into *umbelliferone* and *sagaresitannol,* $C_{24}H_{27}O_4.OH$. This latter yields on oxidation *oxypicric acid.* The oil is pale yellow, very fluid, lighter than water, and of a disagreeable alliaceous odor. Sagapenum was formerly used in *doses* of from ten to thirty grains (0.65–2.0 Gm.) in *amenorrhea, hysteria,* etc.; also externally in plasters as a discutient.

Sage. *Salvia. U. S. VIII. Garden Sage. Meadow Sage. True Sage. Save. Sauge,* Fr. *Folia Salviæ,* P. G. *Salbei,* G.—"The dried leaves of *Salvia officinalis* Linné (Fam. *Labiatæ*)." *U. S. VIII. Sage* is a perennial low shrub or subshrub, up to two feet high, with a quadrangular, pubescent, branching, shrubby stem, furnished with opposite, petiolate, ovate-lanceolate, crenulate, wrinkled leaves, of a grayish-green color, sometimes tinged with red or purple. The flowers are blue, variegated with white and purple, and are disposed on long terminal spikes, in distant whorls, each composed of a few flowers, and provided with ovate, acute, deciduous bracts. The calyx is tubular and striated, with two lips, of which the upper has three acute teeth, the under two. The corolla is tubular, bilabiate, ringent, with the upper lip concave, and the lower divided into three rounded lobes, of which the middle is the largest. The filaments are supported upon short pedicels, to which they are affixed transversely at the middle. The fruits are black nutlets borne in open cups.

Sage grows spontaneously in Southern Europe, and is cultivated abundantly in our gardens. There are several varieties, differing in the size and color of their flowers, but all possessing the same medicinal properties. The flowering period is in June, at which time the plant should be cut, and dried in a shady place. The leaves were officially described as "long and stoutly petiolate, the blade elliptical or ovate-oblong, 3 to 7 Cm. long, obtuse or subacute at the summit, rounded or subcordate at the base, finely crenulate, thick, grayish-green, very pubescent, especially on the under surface, conspicuously reticulate-veined; odor aromatic; taste aromatic, bitter, and somewhat astringent." *U. S. VIII.*

Within recent years sage of commerce has been adulterated with or substituted by *Spanish sage* and *Greek sage.* Spanish sage consists of the leaves of *Salvia lavandulæfolia* Vahl., a perennial herb indigenous to Mexico. Its leaves differ from those of true sage in being usually smaller, whorled on the stems and having a less distinctly crenulate margin and a much smoother surface. *Greek Sage* is the leaves of *Salvia triloba* L., a perennial herb indigenous to countries bordering the Mediterranean. It may readily be distinguished from sage by having usually broader, thicker, shorter and more woolly leaves with a less pronounced crenulate margin and by its odor which is distinct from that of true sage.

Both the leaves and the flowering tops of sage have a strong, fragrant odor, and a warm, bitterish, aromatic, somewhat astringent taste. They abound in a volatile oil, which may be obtained separate by distillation with water. Muir (*J. Chem. S.*, xxxvii, p. 678) found it to contain a terpene boiling at 156° C., another boiling at 171° C., thujone, $C_{10}H_{16}O$, a liquid boiling at from 197° to 203° C., and ordinary camphor, $C_{10}H_{16}O$. In the fresh oil the first terpene predominates. On standing, the amount of thujone increases, and then the camphor. The oil from English leaves contains also a sesquiterpene, $C_{15}H_{24}$, of the boiling point 260° C. Wallach (*Ann. Ch. Ph.*, 1889) states that the first portions contain pinene and cineol, but the greater portion consists of thujone, $C_{10}H_{16}O$ (formerly called *salviol*). Ferrous sulphate strikes a black color with infusion of sage.

By the ancients sage was highly esteemed; it is at present little used, except as a condiment, but has been given in *dyspepsia*, also for *colliquative sweats.* According to Cadéac and Meunier (*Lyons Méd.*, May, 1891,) the volatile oil of sage is a violent epileptiform convulsant, resembling in its action the oil absinthe, but less powerful.

The *dose* of the powdered leaves is from twenty to sixty grains (1.3–3.9 Gm.). *Dose,* of the infusion (one oz. in one pint of boiling water), two fluidounces (60 cc.).

Although the *Salvia officinalis* was the only species of this genus which was recognized by the U. S. P. VIII, many other species share the feeble medicinal properties of sage. *S. pratensis* L., *S. Æthiopis* L., *S. glutinosa* L., and *S. Sclarea* L., or *clarry,* have been officially recognized in Europe, but are less agreeable than is *S. officinalis* and are not much used; the leaves of *S. Sclarea* are said to be introduced into wine in order to impart to it a muscatel taste. The infusion of the *Rocky Mountain sage,* probably *S. lanceolata* Willd., is affirmed by A. Comstock (*T. G.*, 1887, 660) to be valuable as a diaphoretic in *malarial* and *rheumatic fevers,* taken in the form of hot infusion, and when cold to be distinctly tonic and astringent. The *dose* of fluidextract is half a fluidrachm (1.8 cc.).

The seeds of various sages contain enough farinaceous and mucilaginous material to make them useful as food. In the Western United States the ordinary sages of the plains are highly esteemed for fattening cattle, which eat their ripened tops freely (these sages must be distinguished from the so-called "sage brushes" of the West, which belong to the genus *Artemisia*). *Chia* is the seeds of one or more species of *salvia* largely used in Mexico and Southern Arizona by the natives as food. It is affirmed that the variety known as *Chia pinoli* is yielded by *S. columbariæ* Benth. (see *Report U. S. Geogr. Surveys, 100th Merid.*, vol. vi, 48). *S. Chia* was described in the Farmacopea Mexicana as a new species, yielding *chia,* but Mariano Báscena affirms (*La Naturaleza,* 1881) that the common chia-yielding sage of Mexico is *S. polystachya* Ort., while *Chia azul* is yielded by *S. patens* Cav. Guibourt is probably in error in ascribing chia to *S. hispanica* L. The chia seeds are used as food and for the making of mucilaginous poultices. For description of these seeds see (*A. J. P.*, May, 1882, 227–229). The European species, *Salvia verticillata* L., *S. Verbenacea* L., *S. horminum* L. and *S. viridis* L., all indigenous to Central or Southern Europe, are also noted for the mucilaginous character of their seeds, and have on this account been employed to remove foreign substances from the eye. *S. Verbenacea* is sparingly naturalized in waste places in the Middle and Southern States.

Sago. *Sagou,* Fr. *Sago,* G., It. *Sagu,* Sp.—Under this name the U. S. P. formerly recognized the starch obtained from the *sago* palms Numerous trees, inhabiting the islands and coasts of the Indian Ocean, contain a farinaceous pith from which is extracted the starch in enormous quantities. In India and the East Indies it is obtained from several palms, viz: *Metroxylon Rumphii* Mart., *M. læve* Mart., *M. Sagu* Rottboell and allied species (Fam. *Palmæ*). It has also been obtained from *Cycas revoluta* L. and other cycads.

The fruit of the *Cycas circinalis,* according to J. van Donjen, contains a poisonous glucoside, *pakoëine.* (*P. J.*, May, 1903.)

According to H. von Rosenberg (*Proc. A. Ph. A.*, xxvii, 140), pith cells of these palms consist mostly of starch when the large leaves have fallen off and the flowers are just taking their place. At this time the tree is felled, and the trunk cut into billets six or seven feet long, which are split in order to facilitate the extraction of the pith. This is obtained in the state of a coarse powder, which is mixed with water in a trough having a sieve at the end. The water, loaded with farina, passes through the sieve, and is received in convenient vessels, where it is allowed to stand till the insoluble matter has subsided. An average palm about fifteen years old will yield from 300 to 400 kg. of sago starch. It is then strained off, and the farina which is left may be dried into a kind of meal or molded into whatever shape may be desired. For the consumption of the natives it is usually formed into cakes of various sizes, which are dried, and extensively sold in the islands. The commercial "Pearl" sago is prepared by forming the meal into a paste with water, and rubbing it into grains. It is produced in the greatest abundance in the Moluccas, but of the finest quality on the eastern coast of Sumatra. The Chinese of Malacca refine it so as to give the grains a fine pearly luster. Malcolm states that it is also refined in large quantities at Singapore.

Pearl sago is that which is now generally used. It is in small grains, about the size of a pin head, hard, whitish, of a light brown color, in some instances translucent, inodorous, and with little taste. *Common sago* is in larger and browner grains, of more unequal size, of a duller aspect, and frequently mixed with more or less of a dirty looking powder.

Sago meal is imported into England from the East Indies. It is in the form of a fine amylaceous powder, of a whitish color, with a yellowish or reddish tint, and of somewhat musty odor.

Sago starch grains occur both in the altered and unaltered condition in the commercial article. They are avoid, muller-shaped or irregularly 3- or 4-sided with rounded angles; simple or 2-, 3- or 4-compound, the larger grains 30 to 60 or rarely up to 80 microns in length; the hilum circular, excentric and often radiately fissured; lamellæ excentric and concentric; polarization crosses distinct.

Common sago is insoluble in cold water; but by long boiling unites with that liquid, becoming at first soft and transparent, and ultimately forming a gelatinous solution. Pearl sago is partially dissolved by cold water, probably owing to the heat used in its preparation. Chemically considered, it is a very pure natural starch, as the nitrogenous mater rarely amounts to more than one per cent. and the ash to one-half per cent., the remainder being starch and moisture.

Potato starch is sometimes prepared so as to resemble bleached pearl sago, for which it is sold, But, when examined under the microscope, it exhibits larger granules, which are also more regularly oval or ovate, smoother, less broken, and more distinctly marked with lamellæ than are those of sago, and the hilum often cracks with two slightly diverging slits. Imitation sago is now made in the United States from various kinds of starch.

Sago is used exclusively as an easily digestible, non-irritating food. It is given in the liquid state, and in its preparation care should be taken to boil it long in water, and stir it diligently, in order that the grains may be thoroughly dissolved. Should any portion remain undissolved, it should be separated by straining. A tablespoonful to the pint of water is usually sufficient.

Salacetol. *Salicyl-acetol. Salantol.* $C_6H_4(OH)CO.OCH_2CO.CH_3$.—A synthetic product, the ester of salicylic acid and acetylcarbinol, introduced as a substitute for salol, to avoid the elimination of phenol in the system. Crystallizes out of alcohol in white or pinkish needles, fusing at 71° C., slightly soluble in cold water and alcohol, readily soluble in ether, chloroform, and petroleum benzin. It may be used when salol is indicated, in *doses* of from fifteen to forty-five grains (1.0–3.0 Gm.).

Salamander Alkaloids.—*Salmander maculosa*, and probably other newts, produce a poisonous secretion from the skin, from which Hoppe-Seyler and Zalesky separated an active body, *salamandarine*. E. S. Faust (*A. E. P. P.*, xliii) has secured crystalline salts from this body which produce in the lower animals restlessness, excited reflex activity, and convulsions ending in total paralysis. A second alkaloid, *salamandaridine*, was also separated by Faust.

Salep. *Tubera Salep*, P. G.—This name is given to the dried tuberous roots of many species of the genus *Orchis*, and other allied genera of the *Orchidaceæ*. At present the salep of European commerce is prepared chiefly in the Levant, but to some extent in Germany and other parts of Europe. The tubers are collected from wild plants growing in Asia Minor, Southwest Asia, France and Germany. They are divested of their brown outer covering, washed, boiled and dried. The German salep is said to be more translucent than the Levant.

The commercial supplies of salep are shipped chiefly from Smyrna and Constantinople and to a limited extent from Germany.

Salep is in small, oval, irregular, ovoid or oblong tubers, rarely palmate (as tubers from *Orchis maculata* and *Orchis latifolia*) hard, horny, semi-transparent, of a yellowish color, a feeble odor, and a mild insipid mucilaginous taste. It is sometimes kept in the state of powder. In composition and relation to water it is closely analogous to tragacanth, consisting of bassorin with a smaller amount of a water soluble gum and minute quantities of saline matters. It also occasionally contains a little starch. It is highly nutritive, and may be employed for the same purposes as tapioca, sago, etc. Its medieval and Oriental reputation as an aphrodisiac is unfounded. On account of its hardness, salep, in its ordinary state, is of difficult pulverization; but the difficulty is removed by macerating it in cold water until it becomes soft, and then rapidly drying it. *Royal salep*, said to be much used as a food in Afghanistan, has been identified by J. E. T. Aitchison as the product of *Allium Macleanii* Baker. (Fam. *Liliaceæ*.) (*P. J.*, Sept., 1889.)

E. Reeb stated that salep possesses, like diastase, the property of coagulating milk, which he attributes to *erythrodextrin*, but finds that this body, in distinction from diastase, will retain its coagulating property even after heating it to 100° C. (*Journ. der Pharm. v. Elsass-Lothringen*, 1912, No. 8.)

Sal-ethyl. *N. N. R.* 1924. *Ethyl-Salicylate.* $C_6H_4(OH)COOC_2H_5$.—This proprietary ester is used after the manner of, and for the same purposes as, methyl salicylate. It is a colorless volatile fluid of pleasant odor and taste. Sp. gr. 1.184 and boiling at 231.5° C. The *dose* is five to fifteen minims (0.3–1 cc.).

Saligallol. *Pyrogallol Di-salicylate.*—A resinous solid, soluble in two parts of acetone and fifteen parts of chloroform. Its solution in acetone has been used as an external application in skin diseases.

Saligenin. *N. N. R.* 1924. *Ortho-oxybenzyl alcohol*, $C_6H_4.OH.CH_2OH$, is the decomposition product of the glucoside *salicin*. Under the name of *antiarthrin*, a substance has been introduced into commerce which is said to be a combination product between *saligenin* and tannin. It readily undergoes decomposition. It has been used in chronic *rheumatism* and *gout* in doses of eight to twenty grains (0.5–1.2 Gm.) four to six times a day.

It has been recommended as a local anesthetic by Wethall and Thomas (*Jour. of Urol.*, 1922, vii, p. 329). See also under *Salicinum*, Part I.

Salimenthol.—*Samol. Salicylic Ester of Menthol*, $C_6H_4(OH)COO.C_{10}H_{19}$, is an almost colorless fluid, insoluble in water, but miscible with alcohol, ether, chloroform and fatty oils in all proportions.

It is supposed to exercise the virtues of both of its constituents and is employed in various rheumatic and painful conditions by external application with the idea that it will act as a local anodyne by virtue of its menthol radical and being absorbed will exercise the analgesic effect of salicylic acid. It may be applied in the form of a 25 per cent. ointment. It has also been administered internally in *doses* of eight to fifteen drops (0.5–1.0 Gm.), generally enclosed in capsules.

Salipyrin. *N. N. R.* 1924. *Antipyrine Salicylate. Salazolon.* $C_{11}H_{12}N_2O.C_7H_6O_3$.—Prepared by the action of salicylic acid upon antipyrine, either at 100° C. or in solution. It occurs as a white, coarsely crystalline powder, odorless, with a somewhat sweetish taste. It is readily soluble in alcohol and in benzene, and crystallizes from the former in hexagonal tables with a melting point of 91.5° C. According to Guttmann and to Kollmann (*Internat. Klin. Rundsch.*, Sept., 1890; also *M. M. W.*, Nov., 1890), it is an active antipyretic and antirheumatic, which rarely produces toxic symptoms, although an eruption resembling that caused by antipyrine has been noted. Kollmann states that it sometimes causes vomiting, and the daily *dose* should not exceed forty-five grains (3.0 Gm.), and always be less than this in the beginning, as some individuals are intolerant of it. *Salipyrin* has been used to a considerable extent in all forms of *rheumatic diseases*, in *influenza*, in various *fevers*, in *migraine*, and in the whole class of diseases in which its component constituents have been found to be useful; also locally in *coryza*. Salipyrin has been very highly praised by Beuttner as a sedative antihemorrhagic remedy, in all forms of *metrorrhagia* not dependent upon severe organic disease, in threatened *abortion*, and in *dysmenorrhea*. The usual *dose* is from seven to fifteen grains (0.45–1.0 Gm.), in capsule or tablet, repeated every three or four hours, until not over 45 grains (3 Gm.) have been taken.

Salit. *Salicylic Ester of Borneol.* $C_{10}H_{17}O.CO.C_6H_4.OH$.—It occurs as an oily fluid, insoluble in water, but readily soluble in alcohol, ether, and oils. It is incompatible with alkalies and alkaline salts.

Salit is employed for the purposes of the endermic administration of salicylic acid in *neuralgia*, and acute and chronic *rheumatic disorders*. In a few instances its application has given rise to a slight irritation of the skin. It should generally be diluted with equal portions of olive oil, and one-half to one teaspoonful of the mixture applied with friction or by painting over the infected part and covering with an impermeable dressing.

Salix. *Willow-bark. Weidewinde,* G. *Ecorce de Saule,* Fr.—Most of the species of the large genus *Salix* are possessed of similar medicinal properties. (For elaborate study of various willow barks see *Wellcome Chemical Research Laboratory Report,* No. 39.) *S. fragilis* L. or *Crack Willow,* which has been introduced into this country from Europe, is said by Sir James Smith to be the most valuable species. *S. purpurea* L., the *Basket Willow,* a European species, is stated by Lindley to be the most bitter, and *S. pentandra* L., or *Laurel-leaf Willow,* is preferred by Nees von Esenbeck. Many native species are in all probability equally active with the foreign.

Salix alba L., the species formerly recognized by the U. S. Pharmacopœia (1880), is the common European or *white willow.* It has sparingly escaped from cultivation, growing from New Brunswick and Ontario southward to Pennsylvania. It is a large tree with a rough grayish bark, the twigs being brittle at the base, and in this respect somewhat resembling *S. fragilis.* The leaves are pubescent on both surfaces and finely serrulate. It hybridizes with other species of *Salix.* It flowers in April and May, and the bark is easily separable throughout the summer. That obtained from the branches rolls up when dried into the form of a quill, from 0.5 to 1 mm. thick, has a brown, more or less finely warty periderm, is flexible, fibrous, and of difficult pulverization. The inner surface is brownish-white, and smooth, separating in thin layers. Willow bark has a feebly aromatic odor and a peculiar bitter astringent taste. It yields its active properties to water, with which it forms a reddish-brown decoction. Pelletier and Caventou found among its ingredients, tannin, resin, a bitter yellow coloring matter, a green fatty matter, gum, wax, lignin, and an organic acid combined with magnesia. The proportion of tannin is so considerable that the bark has been used for tanning leather. The characteristic constituent of all species of willow, however, is *salicin.* (See *Salicinum.*) Robert W. Beck (*A. J. P.*, 1891, 581) has determined the relative percentages of salicin and tannin as follows:

	Salicin.	Tannin.
Leaves of *S. lucida* Muhl	0.30 per cent.	6.48 per cent.
Bark of *S. lucida* Muhl	1.09 " "	3.58 " "
Bark of *S. alba* L............	0.56 " "	4.26 " "
Bark of *S. nigra* Marsh......	0.73 " "	3.29 " "

Jowett and Potter made an examination of thirty-three samples of willow and poplar, and found in but one (*Salix discolor* Muhl.) the related glucoside *salinigrin,* which Jowett had previously discovered in an unknown sample of willow bark. This compound has the formula $C_{13}H_{16}O_7$, and on hydrolysis yields glucose and meta-hydroxybenzaldehyde. (*Wellcome Chem. Research Laboratory Report,* No. 28.)

The green aments or floral buds have been recommended by certain eclectic practitioners as a sexual depressant, useful in *spermatorrhea,* and other forms of *sexual excitement,* and in the nervous disturbances of the menstrual period. From twenty to thirty minims (1.3–1.8 cc.) of the fluidextract are to be given four times a day.

Salocoll. *Phenocoll Salicylate.* $C_6H_4(OC_2H_5)$-$NH.COCH_2.NH_2C_7H_6O_3$.—This substance forms fine white crystalline needles of sweet taste and soluble in hot water. It combines the properties of phenocoll and salicylic acid, being used in *rheumatic affections* in *doses* of nine to fifteen grains (0.6–1.0 Gm.) several times daily.

Salophen. *Phenetsal. N. N. R.* 1924.—*Acetylparaminophenol Salicylate,*
$C_6H_4\left\{\begin{matrix}OH\\COOC_6H_4.NH(C_2H_3O)\end{matrix}\right.$, is formed by the combination of salicylic acid with acetylparamidophenol, and contains 51 per cent. of salicylic acid. It forms small white crystalline scales melting at 187° C., and is almost insoluble in cold water; moderately soluble in alcohol and ether. In warm alkaline solution it undergoes decomposition into salicylic acid and acetylparamidophenol. According to Siebel (*Th. M.*, Jan., 1892), this reaction takes place in the intestines. It has been used by various clinicians in all forms of *rheumatic diseases* and is undoubtedly effective, though less certain in its action than are the simple salicylates. It is also used to some extent as an analgesic in the pains of nervous diseases and as an intestinal antiseptic. Locally it is sometimes applied to relieve *itching* in various *skin diseases.*

Dose, ten to fifteen grains (0.65–1.0 Gm.); not more than seventy-five grains should be given daily.

Saloquinine. *Salochinin.* $C_6H_4.OH.CO.O.C_{20}$-$H_{23}N_2O$.—This is the quinine ester of salicylic acid and occurs in colorless crystals, insoluble in water, freely soluble in alcohol and ether, fusing at 130° C. Acids or strongly acid salts decompose it, splitting it up into its constituents. It is tasteless and is said not to disturb the digestion or to cause tinnitus aurium, although it is very slowly absorbed. It is said to contain 70 per cent. of quinine, and has been used successfully as an antiperiodic, but is reputed to be of special value in the treatment of malarial and other *neuralgias,* also in fulgurant pains, and has also been highly commended in *typhoid* and other *fevers* as an antipyretic. If in a fever it be administered directly after the cold bath, it begins to powerfully impress the system about the time the effect of the immersion is going off. It may be given in the single *dose* of from fifteen to thirty grains (1–2 Gm.), repeated within twenty-four hours in bad cases of *rheumatic affections.*

Saloquinine Salicylate. *Rheumatin.* C_6H_4.-$OH.CO.O(C_{20}H_{23}ON_2).C_6H_4OH.COOH$.—A white, tasteless powder. Slightly soluble in water, readily in chloroform and ether. It is used in *neuralgia, rheumatism,* etc., in fifteen-grain (1 Gm.) *doses.*

Samandera Bark.—This is the inner bark of *Samandera indica* Gärtn., a tree belonging to the *Simarubaceæ,* growing in Ceylon and the East Indies. It is intensely bitter, and probably contains quassin. For further particulars, see ***P. J.***, 1872, 541.

Sandarac. *Sandaraca. Gum Juniper.*—A resinous substance obtained from the *Callitris quadrivalvis* Vent. (*Thuja articulata* Vahl.), an evergreen tree (Fam. *Pinaceæ*) growing in the mountains of northwestern Africa.

Sandarac is a resinous exudation which occurs as a natural secretion in schizo-lysigenous reservoirs in the bark. It exudes naturally, but an increase in yield is obtained by cutting through the bark. The exuding resin hardens and is collected. It is sent by the natives to Mogador, Casablanca and Nazagan, from which points it is shipped to London, Trieste, Marseilles and Hamburg. It occurs in small, irregular, roundish oblong grains or tears, of a pale yellow color, and with a dusty surface, more or less transparent, dry and brittle, breaking into powder under the teeth, of a faint, agreeable odor increased by warmth, and of a resinous, slightly acrid taste. It melts with heat, diffusing a strong balsamic odor, and easily inflames. It is almost entirely soluble in ordinary alcohol, and entirely so in that liquid when anhydrous, and in ether. Heated oil of turpentine also dissolves the greater part of it, but very slowly. According to Unverdorben, it consists of three resins, varying in their relations to alcohol, ether, and oil of turpentine. The *sandaracin* of Geise, which remains after sandarac has been exposed to the action of ordinary alcohol, is a mixture of two of these resins. Tschirch (*Harze und Harzbehälter*) has isolated and described an acid, *sandaracolic acid,* $C_{44}H_{64}O_4(OH)COOH$, making up 85 per cent. of the natural resin and *callitrolic acid,* $C_{64}H_{82}O_5(OH)COOH$, of which 10 per cent. is present. In Australia and Tasmania *Callitris verrucosa* R. Brown trees grow in vast numbers, and produce a sandarac which is almost colorless, having highly refractive power, and a pleasant aromatic odor, becoming dark by age, and sometimes assuming a superficial mealiness. This *Australian sandarac* softens easily, but does not melt in boiling water, is gritty to the touch, and can scarcely be distinguished from the African drug. (*P. J.*, Jan., 1890.) It is claimed by Greenish (*M. M.*, 1920, p. 471) to contain more volatile oil and more inactive pimaric acid than the African article. For an elaborate description of Australian sandarac, see also *A. J. P.*, 1896, 215.

Sandarac was formerly used internally, and as an ingredient of various ointments and plasters. At present it is used chiefly as a varnish and as incense; its powder, termed *pounce,* is rubbed upon paper to prevent ink from spreading after letters have been scratched out. It is sometimes adulterated with mastic, rosin and dammar. A false sandarac has been described by R. Haneke. It resembled the real article, being lemon-yellow in color, transparent, and the tears elongated and rounded at the tips. When chewed it broke into fine powder and stuck to the teeth, while it softened on the water bath and flowed together into a resinous mass. Examination showed it to consist largely of colophony. (*O. Z.*, liv.)

Sanicula. *Sanicula marilandica* L. *Sanicle,* Fr. *Sanikel,* G. (Fam. *Umbelliferæ*).—The root of this indigenous perennial herb is popularly known in some parts of the country by the name of *black snake-root.* It is fibrous and of an aromatic taste, and, according to C. I. Houck (*A. J. P.*, vol. xiv, 463), contains a volatile oil and a resin. It has been used in *intermittent fever,* and also in *chorea* by Zabriskie. *Dose* of powder to children eight years old, half a drachm (2.0 Gm.) three times a day.

Sanitas.—This name is given to a fluid prepared by forcing air through a mixture of Russian turpentine oil and water, heated at 60° C. for a period ranging from 4 to 12 days. Among the various oxidation products is a soluble camphor ($C_{10}H_{16}O_3$), remaining dissolved in the oil, also a peroxide. It is used as an application for *burns, sores,* and *skin diseases,* and as a general disinfectant for sick rooms.

Sanoform. *Di-iodo-methyl Salicylate.*

$$C_6H_2\begin{matrix}\diagup COOCH_3\\ —OH\\ \diagdown I_2\end{matrix}$$

.—This substance is obtained by the action of iodine on methyl salicylate. It is a crystalline, colorless, odorless, and tasteless powder, permanent in the light and air, and melting at 110° C., but may be heated up to 200° C. without decomposing. It is soluble in 200 parts of cold or 10 parts of hot alcohol, and readily in ether, chloroform, benzene, and carbon disulphide, but almost insoluble in water or glycerin. It contains 62.7 per cent. of iodine. It forms, with caustic alkalies, salts which are sparingly soluble in water.

Sanoform, first introduced as a substitute for iodoform by A. Arnheim, would appear to afford an efficient antiseptic dressing for wounds. As it remains unchanged at high temperatures, it is readily sterilized, while its odorlessness gives it a great advantage over iodoform. Its absorption is extremely slow, as it does not appear in the urine after having been administered hypodermically until twenty-four hours have elapsed, and does not entirely disappear until after fourteen days. It is seemingly, therefore, less poisonous than iodoform. It may be used as a dusting powder or in the manufacture of a 10 per cent. gauze which can be sterilized by heating; or a 1 per cent. solution in collodion, or a 10 per cent. ointment may be employed. It has been employed with satisfaction in ophthalmic surgery by Radziejewski and by Jacobsohn.

Santolina.—A composite plant, commonly called *Holy herb, Heiligenpflanzen, Cypress herb, Cypressenkraut* (*Santolina Chamæcyparissus* L.), is stated to have long been used popularly against the *round worm* in Scotland. Maben (*P. J.*, xvi, 301) found in it a volatile oil and a considerable percentage of resin, with a bitter principle, which he believed to be an alkaloid and the active principle of the drug. The decoction of the plant may be made by boiling half an ounce in a pint of water for half an hour, straining and making up to a pint. It is given in *doses* of five fluidounces (150 cc.) to adults and half that quantity to children, repeated for four mornings, and then followed by a brisk cathartic.

Santalol compounds.—There have been put upon the market a number of proprietary derivatives of oil of sandalwood. These are used like the oil itself as urinary antiseptics, especially in *urethritis.* The advantage claimed for these compounds over the oil is generally that they are less irritating to the stomach.

Santalol Carbonate. Santalyl Carbonate.—There are on the market two preparations claiming to be carbonic acid esters of santalol. These are known under the trade names of *Blenal* and *Carbosant.* They each occur as yellowish, oily liquid, almost tasteless and odorless, representing 94 per cent. of santalol. They may be given in *doses* of fifteen to twenty minims (1 to 1.3 cc.).

Santalol Camphorate. Camphosal. Camphoral. Santalyl Camphorate.—This is stated to be the neutral camphoric ester of santalol. It is a yellowish brown oil with a faintly aromatic odor and bitter taste. *Dose,* five to fifteen minims (0.3–1 cc.).

Santalol Salicylate. Santalyl Salicylate. Santyl. N. N. R. 1924.—A yellowish oil with a faint balsamic odor and taste and a specific gravity of 1.07. It yields on saponification approximately 40 per cent. of salicylic acid and 60 per cent. of santalol. Besides its use as a urinary antiseptic in *gonorrhea* and *cystitis,* Menier (*B. K. W.,* 1907) has found it of service as a local remedy in *ozena.* The *dose* is fifteen to twenty-five minims (1 to 1.5 cc.).

Thyresol.—This is said to be the methyl ether of santalol. It occurs as a colorless liquid with a slight sandalwood odor freely soluble in alcohol or ether. According to Knauth (*D. M. W.,* 1909) it does not liberate santalol in the body but appears in the urine as a glycuronic compound. He, however, finds it a useful remedy in *urethritis. Dose,* five to ten grains (0.3 to 0.6 Gm.).

Santalol Formaldehyde.—This combination of formic aldehyde with oil of sandalwood and some inorganic acid is a balsamic yellow fluid which, in the presence of water, is asserted to break up into its components.

Santalol Allophanate.—The allophanic ester (see *Allophanic Acid*) of santalyl is upon the market under the trade name of *allosan.* It occurs as colorless tasteless crystals insoluble in water and representing about 72 per cent. of santalol. The usual *dose* is fifteen grains (1 Gm.).

Sapindus.—Various tropical plants belonging to this genus of the *Sapindaceæ* contain saponin, and are largely used for cleaning purposes. The berries are commonly used, being called "*Soap berries.*" Thus, in India are employed the pulp of the fruit of *Sapindus Mukorossi* Gaertn., the capsules of *S. trifoliatus* L., and in South America the oil and seed vessels of *S. Saponaria* L. The fruits of *S. rarak* DC., according to O. May, contain saponin and a fixed oil. (*A. Pharm.,* 1906, 25.) Asahina and Shimidzu (*J. P. C.,* 1916, xiv, 188) extracted from the pericarp of *S. mukurosi* a pure saponin exhibiting an optical rotation of + 13.28° at 20° C. and hydrolyzing to form sapogenin and arabinose.

Sapium. *Sapium sebiferum* (L.) Roxb. *Chinese Tallow Tree. Vegetable Tallow. Tankawang Fat.*—This is a species of the family *Euphorbiaceæ,* cultivated in the Chinese provinces of Kiangse, Kiang-sou, and Chih-kiang for the sake of the solid fixed oil which covers the seeds. The "tallow" occurs in hard, brittle, opaque, white masses of about eighty pounds' weight. It consists chiefly of palmitin with a little stearin and is said to be nearly pure stearin. The oil is largely used for lighting purposes. The remnants of the nut are employed as fuel and as manure. (See *P. J.,* 1883, 401, and 1887, 901.)

Saponaria. *Saponaria officinalis* L. *Soapwort. Bouncing Bet. Fuller's Herb. Sheep Weed. Saponaire. Savonnière,* Fr. *Seifenwurzel,* G. (Fam. *Caryophyllaceæ.*)—A perennial herb, having oblong-lanceolate, 3-nerved leaves and panicled cymes of pink or nearly white flowers. Though indigenous to Europe, it is common along roadsides and waste places in the United States. The rhizome and roots are employed. The rhizomes are cylindrical, from 5 to 12 cm. long and 5 to 12 mm. thick, outer surface being reddish-brown. The fracture is short and even. They are inodorous, and of a taste at first bitterish and slightly sweetish, afterwards somewhat pungent, continuing long, and leaving a slight sense of numbness on the tongue. They impart to water the property of forming a lather when agitated, like a solution of soap, whence the name of the plant was derived. This property, as well as the medicinal virtues of the plant, resides in *saponin,* $C_{32}H_{54}O_{18}$. This principle constitutes, according to Bucholz, its discoverer, 34 per cent. of the dried root which contains also a considerable quantity of gum and a little bassorin, resin, and altered extractive, besides lignin and water.

Saponin.—The term saponin is applied to a number of glucosidal principles which have in common the property of foaming when shaken with water and of forming emulsions with fixed oils and resinous substances and of preventing the deposition of finely divided precipitates.

They are homologous substances having the general formula $C_nH_{2n-8}O_{10}$. They vary considerably in physiological action, the more powerful ones being called *sapotoxins.* They are colloids and not dialysable.

They usually have a biting acrid taste and are powerfully sternutatory.

The saponins can be separated by several methods, the earliest suggested being that of Gehlen who dissolved them out of the crude drug with boiling alcohol from which on cooling they spontaneously separate or may be precipitated by ether. Some of them, however, are soluble in cold alcohol and therefore not recoverable by this method. A second method is that of Tromsdorf who precipitated the saponin from either a decoction or a hot alcoholic extract, first with neutral lead acetate, which precipitates in an acid saponin, and the filtrate is then treated with basic lead acetate which precipitates the neutral saponins. A third method depends upon their precipitation with saturated solution of caustic baryta. By this method it is probable that there is some change in the chemical composition of the molecule. The fourth method, which is useful for some of them, is that suggested by Kobert of salting out with ammonium sulphate.

The saponins are mostly neutral in reaction although there is a small group which are acid. Both the acid and the neutral saponins, however, will form salt-like combinations with barium and other bases. On heating with diluted mineral acids they are decomposed, yielding some kind of sugar. When heated with caustic alkalies a fatty acid complex is separated. They are therefore classed as glucosides. (See Kobert, *Bio-Chemisches Hand lexikon,* 1912, vii.)

The saponins are widely distributed through the vegetable kingdom. Among the plants, considered elsewhere in this work, which yield saponin are quillaia, dioscorea, guaiacum, helonias, aesculus, senega, sarsaparilla, ginseng, cainca, saponaria, digitalis, etc.

Saponin has been found in many other plants, among them some species of *Silene, Dianthus,* and *Lychnis,* in *Vaccaria vulgaris* Host., and in *Agrostemma Githago* L., all belonging to the Fam. *Caryophyllaceæ.* Serious poisonings by the mixture of the seeds of *Agrostemma Githago* with wheat have been reported. (*D. M. W.,* 1903.) According to Augustine Henry, there are at least eleven species of trees whose products are used in China for washing purposes and probably contain saponin, which is also found to the extent of 10 per cent. in the seeds of the Chinese tea oil tree, and is left in such large proportion in the refuse after the extraction of the oil that the "tea seed cake" is used as a fish poison. (*Am. Drug.*, 1896.) In California the *Indian Soap Root*, *Chlorogallum pomeridianum* (Ker.) Kunth., is much used for washing clothes; it probably contains saponin.

Yucca filimentosa L., familiarly known as *Adam's needle* or *Spanish bayonet*, a liliaceous Mexican plant, has long been used by the Indians as a cleansing agent and contains a considerable amount of a special saponin. It has become a plant of some commercial importance in Kansas under the colloquial name of *soap weed.* (See *D. C.*, 1917, lxi, 42.)

The saponins have been employed in beverages to give a frothy or foaming effect. The detection of small amounts is very difficult. One method that has been suggested is to test the hemolytic effect of the separated froth.

Many of the saponins are highly poisonous and are therefore known as *sapotoxins.* The toxic effects appear to be due to their affinity for cholesterin and perhaps also lecithin. By virtue of this combination with these important lipoid bodies they are irritant to mucous membranes and when introduced into the circulation destroy the red blood cells and exercise potent effects upon the central nervous system. The variability in their toxic powers may be gauged by the fact that diocin, when mixed with blood, in as dilute solution as 1 in 400,000, will cause hemolysis while chamaelirin (from Helonias) requires a concentration of 1 in 700. Most of the toxic saponins are unable to pass through the intestinal mucous membranes and when taken by the mouth cause only local irritation of the alimentary canal; agrostemma is a noteworthy exception to this rule.

When introduced into the circulation in moderately toxic doses the most obvious symptoms produced by the sapotoxins, are usually on behalf of the nervous system; convulsions followed by motor weakness, and even complete paralysis. Accompanying these nervous symptoms there is often weakness of the heart and evidence of irritation of the serous membranes and eliminating organs. After larger quantities, there is, besides the nervous manifestations, marked failure of the circulation, and vomiting and purging—the ejecta often being bloody. Death is usually due to respiratory failure, but may occur after some days of general exhaustion. When locally applied sapotoxins destroy the contractility of the muscles and the conductivity of the nerves. For studies of the physiological effects of saponins see Ransom (*D. M. W.*, 1901, xxvii, p. 194), Brandl (*A. E. P. P.*, 1905, liv, p. 245 and 1908, lix, p. 299), Yagi (*A. E. P. P.*, 1911, lxiv, p. 141) and Kobert (*Biochem. Handlex*, 1914, vol. vii).

Sarcocolla. *Sarcocolle*, Fr. *Fleischleimgummi*, *Fischleimgummi*, G.—This peculiar gum was formerly thought to be an exudate of the *Penœa fulcata* L. (*Penaceæ*), a small shrub growing in Cape of Good Hope, but according to Tschirch (*Schweiz. Apoth. Zeit.*, 1920, lviii, 113) is a secretion of the stem of the *Astragalus sarcacolla* (*Leguminosæ*) a native of Persia. *Sarcocolla* occurs in the form of small, roundish, irregular grains, somewhat spongy, sometimes agglutinated in masses, at times admixed with fine hairs, friable, opaque or semi-transparent, of a yellowish or brownish-red color, inodorous unless heated, when they have an agreeable odor, and of a peculiar, bitter sweetish, and acrid taste. Sarcocolla, according to Pelletier, consists of 65.3 per cent. of a peculiar substance, considered by Thomson as holding an intermediate place between gum and sugar, and called *sarcocollin*, $C_{13}H_{23}O_6$, 4.6 of gum, 3.3 of a gelatinous matter having some analogy with bassorin, and 26.8 of lignin, etc. It is said to be purgative, but at the same time to produce serious inconvenience by its acrid properties. The Arabian physicians used it internally, and by the ancients it was employed as an external application to wounds and ulcers, under the idea that it possessed the property of agglutinating the flesh, whence its name.

Sarracenia. *Side-saddle Plant. Pitcher Plant. Huntsman's Cup. Water Cup. Sarracenie*, Fr., G. —This is a genus of carnivorous plants belonging to the *Sarraceniaceæ* which includes 7 species indigenous to swamps and savannas of the eastern half of North America. According to E. P. Porcher, the roots of *Sarracenia flava* L., and *S. variolaris* Michx., were at one time used in the southern United States in *dyspepsia.* Sheppard found them to contain lignin, coloring matter, resin, an acid salt of lime, and probably an alkaloid. Stan Martin asserts that he has found in the root—(1) an alkaloid which he proposes to name *sarracenine*, a resin, and a yellow coloring principle. (*Ann. Thér.*, 1866, 73.) E. Schmidt, however, found no alkaloid but discovered *sarracenic acid.* (*A. J. P.*, 1872, 213.) *Dose*, of tincture (two ounces in one pint), a fluidrachm (3.75 cc.); of fluidextract, from ten to twenty minims (0.6–1.3 cc.).

Sassy Bark. *Nkasa. Doom Bark. Casca Bark. Mancona Bark. Saucy Bark. Ecorce de Mançoine*, Fr. *Manconarinde*, G.—This bark is interesting chiefly from its employment by the natives of Western Africa as an ordeal in their trials for witchcraft or sorcery. (For details, see *P. J.*, lxv, 2.) It is obtained from *Erythrophleum guineense* Don, which is a large tree with spreading branches, doubly pinnate leaves, flowers in spike-like racemes, and leguminous fruit. The bark, which is collected from the trunk and branches, occurs in flat or transversely curved pieces, externally of a dull gray, grayish-black or reddish-brown (very old bark) color and marked by reddish-brown warts or circular whitish spots, the old bark being irregularly ridged; fracture hard and granular; inner surface dull black or reddish-brown; odor indistinct; taste astringent and slightly bitter. A comprehensive description of *sassy bark* is given in the *Commentar zur oesterreichischen Pharmacopœia*, 1890, by Vogl; and in the *Résumé de la Matière Médicale et Toxicologique Coloniale*, by Corre and Lejuanne, the plant, fruit, seeds, etc., are carefully illustrated. Gallois and Hardy obtained the poisonous principle *erythrophleine.* This alkaloid is a colorless, crystalline solid, soluble in water, acetic ether, alcohol, and amyl alcohol, insoluble in chloroform, benzin, and ether. In contact with sulphuric acid and black manganese oxide, a violet color (less intense than that produced with strychnine) is developed. Harnack and Zabrocki (*A. E. P. P.*, xv, 404) also prepared *erythrophleine*, $C_{28}H_{43}O_7N$, and by the action of hydrochloric acid upon it obtained an acid they call *erythrophleic acid*, and a volatile alkaloid they call *mançonine.* The bark yields its virtues to water. Power and Salway examined sassy bark in 1912 and confirmed the presence of erythrophleine as described by Harnack. (*A. J. P.*, 1912, 337.)

The physiological action of erythrophleine has been studied by various observers, especially by Harnack and Zabrocki, and Lauder Brunton, with results which are fairly concordant. Erythrophleine exercises a digitalis-like action on the circulation causing a slow, strong pulse, with a rise in the arterial pressure. These changes are certainly in great part due to the direct action upon the heart, but are also seemingly in part produced by a stimulating influence upon the muscle fibers or nerves in the walls of the arterioles. Purging was also noted as the result of an increased peristalsis, thought to be due to the local action of the poison. Vomiting is believed by Lauder Brunton to be the result of an influence upon the nerve centers, because it occurs when the alkaloid is given hypodermically. In fatal poisoning in the lower animals, convulsions are pronounced, and the respiration is also markedly affected. In 1888 Lewin asserted erythropleine to be a powerful local anesthetic, whose action is more pronounced than that of cocaine. His paper gave rise to an extraordinary controversy, the outcome of which appears to be that, although the alkaloid is possessed of moderate anesthetic powers, it is for various reasons practically not useful. (See *U. S. D.*, 17th edition, p. 1739.) A 50 per cent. solution in eugenol has been used under the name of *throphleol* to devitalize dental pulp.

Germain Sée asserts (*Méd. Mod.*, Dec., 1891) that, although sassy bark does not act well upon the heart, it gives great relief in *dyspnea*, the number of respirations being lessened and the inspirations being extraordinarily increased in depth. He gave of the alkaloid from one-fortieth to one-thirtieth of a grain (0.0016–0.002 Gm.); of the extract, from one-fourth to one-third of a grain (0.016–0.021 Gm.).

Satureja. *Satureia hortensis* L. *Summer Savory; S. Montana* L. *Winter Savory. Sarriette,* Fr. *Bohnenkraut,* G.—Annual labiate plants resembling thyme in odor and flavor, growing spontaneously in the south of Europe, cultivated in our gardens as culinary herbs, and sparingly naturalized from New Brunswick to Michigan and southward.

Saururus. *Saururus cernuus* L. *Lizard's Tail.* (Fam. *Saururaceæ.*)—D. L. Phares, of Newtonia, Miss., considered this indigenous swamp plant of the eastern and central United States useful in irritation of the kidneys, bladder, prostate, and urinary passages generally. The *dose* of the strong infusion was, with the plant either fresh or dried, from one to four fluidounces (30–120 cc.) every fifteen or thirty minutes, or three or four times a day. (*A. J. P.*, 1867, 468.)

Saxifraga. *Saxifrage. Rockfoil.* (Fam. *Saxifragaceæ.*)—Garreau and Machelast have isolated from *S. crassifolia* L. and other species of this genus a crystallizable bitter substance, *bergenin.* It is obtained by boiling the stems of the plants with absolute alcohol, after the tannin has been removed by ether. It crystallizes in alcohol, has a bitter taste, melts at 140° C., and is soluble in 167 parts of 90 per cent. alcohol and in 830 parts of water. Its formula is given as $C_6H_3O_3.H_2O$. Bergenin is asserted to be intermediate in its action between salicylic acid and quinine. (*A. Pharm.*, 1881, 293.) The rhizome of *Saxifraga ligulata* Bell, which is used in India in *dysentery*, has been found by David Hooper to contain about 16 per cent. of gallic and tannic acids, but no other active principles. (*P. J.*, Aug., 1888.)

Scarlet Red. *N. N. R.* 1924. *Amido-azotoluol-azo-β-naphthol. Biebreich scarlet. Rubrum Scarlatinum.* $CH_3C_6H_4.N{:}NC_6H_3(CH_3)N{:}N.C_{10}H_5.OH$.—A compound of betanaphthol and diazotized amido-azo-ortho-toluol.

It is a dark brownish-red powder, nearly insoluble in water, slightly soluble in benzene and acetone and easily soluble in chloroform, oils, fats and phenols. It is slightly soluble in cold alcohol, more soluble in hot alcohol, more readily soluble in petrolatum and paraffin. It softens at 175° C., melts between 181° and 188° and decomposes at 260° C. The saturated aqueous solution is of a clean scarlet red color which has a bluish tinge upon dilution or in thin layers. In 1906 Fisher (*M. M. W.*, 1906, liii, 2041) discovered that the dye stuff known as scarlet red had the power of greatly stimulating the growth of epithelial cells. This observation was confirmed by Helmholz (*J. H. H. B.*, 1907, xviii, 365), and in 1908 Von Schmieden (*Cb. C.*, 1908, xxxv, 153) applied it practically for the purpose of stimulating epithelial growths in various surgical conditions, as *chronic ulcers, unhealthy granulations,* and the like. Since then it has been employed by a number of surgeons to stimulate the formation of skin not only in these conditions, but in *bed sores,* in unhealed *ulcers,* following extensive injuries or *burns,* and to promote skin formation after operations. It is usually applied in the form of an ointment containing from 4 to 8 per cent. of the curative agent. When the ulcer is very large it is recommended that the salve should be applied around the edges rather than over the whole surface of the denuded area. It has also been employed by Wolfrum and Cards (*M. M. W.*, 1909, p. 242) in the treatment of *corneal ulcers* after the loss of cornea whether due to injury or ulceration and by Rabaudi (*S. M.*, 1909, p. 344) in *sore nipples* and *erosions of the uterus.*

When the wound is suppurating profusely, scarlet red is of little value. It should be reserved for clean, dry ulcers which show little tendency to heal. It may be applied either in the form of the eight per cent. ointment or as a powder diluted with boric acid. It is not an entirely harmless remedy, for Lyle (*N. Y. M. R.*, Nov. 16, 1912) has reported a case of serious poisoning, characterized by nausea and vomiting, epigastric pain with fever following the application of scarlet red over extensive ulcerated surfaces. Irritation of the kidney has also been attributed to its use.

The success which followed the use of scarlet red has led to the introduction of a number of related substances for similar use. Hayward (*M. M. W.*, 1909, p. 1836) from his experiments concluded that *ortho-amido-azotoluol,* a substance closely allied to scarlet red, was even more efficacious than scarlet red. Amido-azotoluol has the chemical formula $CH_3C_6H_4N.NC_6H_3(CH_3)(NH_2)$. Amido-azotoluol forms red crystals or a reddish-brown powder melting at 100° C. It is insoluble in water but readily soluble in alcohol, chloroform and ether. It is also soluble in fatty oils. Curbski (*Cb. Chir.*, 1910) has reported a case of poisoning from the use of an ointment of this in which the symptoms resemble those of aniline poisoning. According to Curschmann (*Th. M.*, 1911, p. 717) the acetylization of amido-azotoluol diminishes its toxicity and does not affect its therapeutic value. Preparations of this type are on the market under the names of *azodermin* and *epithermol.*

Diacetyl-amido-azotoluol has been marketed under two proprietary names—*pellidol* and *dimazon.* Similar therapeutic properties are claimed for sodium dimethylaminoazobenzene-*m*-sulphonate, which is sold under the name of *azophen. Azodolen* is a mixture of equal parts of pellidol with an iodol compound called *iodolen.*

Schinus. *Schinus Molle* L. *Peruvian Mastic-Tree. California Pepper-Tree.* (Fam. *Anacardiaceæ.*)—The *pepper tree* of Peru yields a drupe the size of a pea, having a flavor similar to a mixture of pepper and fennel. It has been introduced as a shade tree in Southern California. (*A. J. P.*, 1896, 215.) The leaves contain a volatile oil which is readily discharged, as after a rain when the air is filled with fragrance. Schimmel & Co. examined the volatile oil distilled from the berries; it had the sp. gr. 0.850, the odor of phellandrene, and was soluble in alcohol. (*Ph. Rev.*, 1897, 114.) It has been used in *gonorrhea* as a substitute for cubeb. The leaves, bark, and gum resin have also been employed medicinally. (See *A. J. P.*, 1890; *P. J.*, 1887.)

Scolopendrium. *Scolopendrium vulgare* Smith. *Scolopendrium Scolopodendrium* (L.) Karst. *Asplenium Scolopendrium* L. *Phyllitis Scolopendrium* (L.) Newman. *Hart's Tongue.* (Fam. *Polypodiaceæ*).—The fronds of this fern, which is indigenous in Europe and Asia, have a sweetish, mucilaginous, and slightly astringent taste, and, when rubbed, a disagreeable oily odor. They were used as a deobstruent in visceral affections, as an astringent in *hemorrhages* and fluxes, and as a demulcent in pectoral complaints.

Scopola. *Scopolia. Belladonna Scopola. Scopola Belladonna. Japanese Belladonna* (incorrectly).—"The dried rhizome of *Scopola carniolica* Jacquin (Fam. *Solanaceæ*), yielding, when assayed as directed below, not less than 0.5 per cent. of its alkaloids." *U. S. VIII.* The genus *Scopola* is the connecting link between *Atropa* and *Hyoscyamus*, resembling *Atropa* in leaf and flower and in the microscopical character of its rhizome, but differing in that its fruit is not a berry but is a pyxis, so resembling that of Hyoscyamus. For description of drug and its histological study, see Kraemer, *A. J. P.*, 1908, p. 459. The Japanese plant, *S. japonica* Maxim., is so closely allied to *S. carniolica* that its specific distinction is very doubtful; it has been separated upon the characters of the style being curved, the calyx-teeth unequal and the leaves less obovate and having much longer petioles than *S. carniolica;* but Holmes has shown that the curved style occurs in *S. carniolica. S. carniolica* is a common plant in Bavaria, Austro-Hungary, and Southwestern Russia, usually in the hilly districts, where it grows in damp, stony places. Its general appearance is that of the belladonna, but it is much shorter, rarely growing above a foot in height, has thinner leaves, and is especially distinguished by its fruit being a transversely dehiscent capsule (pyxis), and by the presence of a distinct rhizome.

The rhizome was officially described as "of horizontal growth, more or less curved and shortly and sharply flexuous, cylindraceous and somewhat flattened vertically, occurring mostly in pieces from 2.5 to 7.5 Cm. long and 0.8 to 1.6 Cm. broad, often split before drying; upper surface marked with closely set, large, cup-shaped stem scars, margins irregularly contracted; externally varying from yellowish-brown to dark brownish-gray, finely and irregularly wrinkled longitudinally, obscurely annulate and more or less nodular-roughened; fracture short and sharp, exhibiting a yellowish-white bark, its corky layer dark brown, or pale brown, wood indistinctly radiate, and central pith rather horny; nearly inodorous; taste sweetish, afterwards bitterish and strongly acrid." *U. S. VIII.*

The Japanese rhizome is from 5 to 15 cm. long, about 1 cm. in diameter, rarely branched, cylindrical or slightly compressed, knotty, bent, with circular disk-like scars, of a pale brown color, not whitish when abraded, with a slightly mousy, narcotic odor, and a taste nearly free from bitterness.

Histologically, Scopola can readily be distinguished from belladonna root by its characteristic reticulate tracheæ and absence of tracheæ with elliptical-shaped bordered pores.

Scopola yields approximately 0.6 per cent. of total alkaloids (see Williams, *Proc. A. Ph. A.*, 1899, 285) of which about 80 per cent, is hyoscyamine and the rest scopolamine and atroscine.

The U. S. VIII recognized a fluidextract (*Fluidextractum Scopolæ*) which was made with a menstruum of 75 per cent. alcohol.

The physiological action and therapeutic effects of scopola very closely resemble those of belladonna. H. C. Wood, Jr. (*T. G.*, April 15, 1901) showed, however, that the scopola was slightly more depressant to the spinal cord than belladonna (evidence of scopolamine action) and that the extracted total alkaloids of scopola were much more toxic than the extracted total alkaloids of belladonna. Scopola has been very little used in this country as an internal medicine but was at one time extensively employed for the manufacture of belladonna plaster. It is also a commercial source of scopolamine and hyoscyamine.

Extract of Scopola, U. S. VIII, was made by evaporating the fluidextract and assaying it so that it contains 2 per cent. of mydriatic alkaloids. *Dose*, one-eighth to one-fourth of a grain (0.008–0.016 Gm.).

Dose, of the drug, one to two grains (0.65–0.13 Gm.); of the fluidextract, one-half to three minims (0.03–0.2 cc.).

Scrophularia. *Scrophularia marilandica* L. (*S. nodosa* var. *marilandica* Gray). *Figwort. Scrofula Plant. Carpenter's Square. Square-stalk. Heal All. Scrofulaire*, Fr. *Kropfwurz. Kontenwurz*, G. (Fam. *Scrophulariaceæ.*)—This rather tall herb, having a knotted root, a square stem, opposite leaves and slender panicles of small, greenish-purple flowers, grows in rich open woods from New York to North Carolina and west to Kansas. Its leaves have, when fresh, a rank fetid odor, and a bitter, somewhat acrid taste; but these properties are diminished by drying. Water extracts their virtues, forming a reddish infusion, which is blackened by ferric sulphate. For histological study of root, see *P. J.*, 1896. Walz has obtained from it two proximate principles, which he names respectively *scrophularin* and *scrophularosmin.* Figwort leaves were formerly employed internally as an alterative and externally as a discutient and as a local application in *hemorrhoids.* Van de Moer (*P. J.*, 1896) affirms that the seeds are toxic, belonging to the digitalis group.

Sedoheptose.—This is a new sugar produced from *Sedum spectabile* B. by La Forge, and Hudson. It has the formula $C_7H_{14}O_7$ and is reducible but not fermentable.

Sedum. *Sedum acre* L. *Biting Stonecrop. Wall Paper. Small Houseleek. Mossy Stonecrop. Joubarbe âcre. Poivre des Murailles*, Fr. *Mauerpfeffer, Steinkraut*, G. (Fam. *Crassulaceæ.*)—This European plant has escaped to some extent from the gardens and grows wild in New England. It is spreading moss-like, possesses small, very thick leaves and yellow flowers. It causes vomiting and purging, and applied to the skin produces inflammation and vesication. The fresh herb and the expressed juice have been used as an antiscorbutic, emetic, cathartic, and diuretic, and have been applied locally to old *ulcers, warts,* and other excrescences. Other species are less acrid, and are even eaten as salad in some parts of Europe. Such are *Sedum rupestre* L., and *S. album* L. *S. Telephium* L. was formerly employed externally to cicatrize wounds, and internally as an astringent in *dysentery* and *hemoptysis,* and is still esteemed by the common people in France as a vulnerary. Ernst Mylius found in 100 parts of *Sedum acre* 2.2 parts of a soft, not acid resin, 12.80 parts of uncrystallizable sugar, and 12.40 parts of a soft acid resin, besides an alkaloid and inert substance. (*J. P. C.*, 4e sér., xvii, 81.)

Selenium. Se = 79.2.—A steel-gray non-metallic element with a high luster and showing a crystalline surface upon being broken. Also in dark red crystals or powder soluble in carbon disulphide and melting between 170° and 180° C. It burns in air with a bluish-red flame evolving selenium dioxide. Sp. gr. 4.27, m. pt. 217° C. It occurs in copper ores and is obtained as a by-product in the copper industry. It is used in the electrical sciences on account of its distinctive property of being a good conductor of electricity when exposed to light but a poor conductor in the dark. This widely distributed element, discovered by Berzelius in 1817, belongs to the sulphur group, and its compounds occur in nature associated with sulphur compounds. It is also extracted from the lead chamber deposits of the sulphuric acid works. The presence of *selenium* in sulphuric acid has been objected to on account of its coloring substances yellow, even minute quantities present in sulphuric acid giving a yellow tint to cellulose. (*P. J.*, 1912, 47.) The physiological actions of the compounds of this metal have not been widely studied, but Chabrié and Sépicque (*C. R. A. S.*, cx) have shown that *selenous acid* is an irritant poison. According to Merck, a solution of selenous acid (0.5 per 100) is a valuable reagent for detecting alkaloids. (*M. R.*, 1900.) Wassermann (*D. M. W.*, 1911) from experiments upon mice reached the conclusion that selenium had a destructive action on *cancerous growths* which has led to some clinical trials of various compounds of the element, especially the combination of *eosin-selenium* and the colloidal forms known as *seleniol* and *electro-selenium.* The treatment must be regarded as still in an experimental stage.

Selenium oxychloride has recently come into use as a solvent. It has selective solvent properties which are peculiarly uncommon and is capable of dissolving such resistant materials as rubber, enamels, hydrocarbons, phenol-formaldehyde condensation products, etc. (*Ph. Era.*, 1921, liv, 120.)

Semecarpus. *Semecarpus venosa* (Fam. *Anacardiaceæ*), the *Tschongott Tree.*—The highly poisonous nature of the bark of this tree, which is a native of the Caroline Islands, is, according to Thoms and Mannich (*Ph. Ztg.*, 1902), due to the presence of *cardol* (*anacardic acid*).

Sempervivum. *Sempervivum tectorum* L. *Common Houseleek. Hen-and-Chickens. Grande Joubarbe,* Fr. *Hauswurz, Hauslauch, Dachwurz,* G. (Fam. *Crassulaceæ.*)—A succulent, perennial, Eurasiatic plant with imbricated leaves and scorpioid cymes of rose-purple flowers arranged on a panicle. It is extensively cultivated. In Europe the bruised recent leaves of this plant are employed as a cooling application to burns and other external inflammations. The juice is said to cure *warts.*

Septovince. *Trichloracetyl-diphenol-diiodide.*—This compound was introduced under the name of *iodal,* but as this title properly belongs to the triiodaldehyde the name was changed to septovince. It is claimed by Sorapure to have specific curative properties in *acute articular rheumatism* (*P. J.*, 1916, xcvii, 463). The method of use is as follows: One part of septovince is shaken with 7 parts of water and allowed to stand for 6 hours at the end of which time there is a dark, tarry deposit and a clear, brown, supernatant liquid. The latter is injected intramuscularly in *doses* of one fluidrachm (5 cc.) daily and also applied locally.

Serums. *Normal Horse Serum. Normal Sheep Serum. Normal Goat Serum.*—These liquids are obtained from the blood of the respective animals by inserting a large sterile needle into a vein and allowing the blood to flow through rubber tubing connected with the needle into covered vessels of one or more liters capacity. The blood is allowed to coagulate for about two days, either around a rod or other device previously inserted in the vessel, or spontaneously in the bottom of the container; the clot at the end of this period may be squeezed free of serum by dropping a weight from the upper part of the vessel. The clot gathers in its meshes the red cells and the white cells of the blood, so that the fluid remaining to be siphoned off is a transparent liquid of a light yellowish brown color. This is called *blood serum.* If the clotting had been prevented by the addition of a citrate or oxalate and the blood cells separated by means of sedimentation, with or without centrifugation, the resulting fluid would be *blood plasma.* If in the third place, the blood had been vigorously agitated by means of rough solid bodies such as pieces of broken glass in the container immediately, upon being withdrawn from the animal, the fibrin or clot would have rapidly formed around these agitating bodies leaving the cells suspended in the fluid; such a fluid is called *defibrinated blood,* it resembles whole blood in appearance, but differs from it in having lost the property of spontaneous coagulation, it differs from serum in containing red blood cells and some white cells. The blood platelets and part of the white cells are destroyed by defibrination. All these operations must be carried out with an aseptic technic more strict than that of the surgical operating room, because blood and the fluids derived from it are excellent culture media for bacteria, and all bacterial contamination, whether pathogenic (disease causing) or not must be excluded. All the instruments and vessels must be sterilized—not by boiling—but in such a manner that even bacterial spores are destroyed. This requires dry heat at 170° C. for an hour and a half. Material such as rubber, which will not withstand this heat, may be sterilized by steam at 15 pounds pressure for half an hour, provided the boiler or autoclave is so arranged that all the air in the interstices of the material to be sterilized is withdrawn and replaced with saturated steam; the usual steam sterilization does not accomplish this.

Even with such precautions, serums are not usually considered safe unless preserved by the addition of some antiseptic, such as 0.5 per cent. phenol or cresol, or chloroform to saturation. As usually administered these quantities of preservative are without serious effect.

The serum of normal animals is used in therapeutics to promote clotting in *hemorrhage* or in hemorrhagic diseases. The other blood fluids described above are not available for this purpose—the plasma on account of its content of citrate or oxalate which prevents clotting, the defibrinated blood and whole blood on account of the red blood cells which they contain; the blood cells of another species might prove harmful to man. It would seem that in blood serum most of the clotting factors have been partially or wholly used up in the production of the clot. Nevertheless, serum has seemed of value in many cases of hemorrhage, though there are other cases in which it is of no value. (See also under *Blood* and *Thromboplastin.*) Fresh serum is apparently more efficacious than old; it is therefore advisable to use serums whose date of production is stated. *Dose,* two and one-half to five fluidrachms (10–20 cc.) hypodermically, or in urgent cases intravenously.

The occurrence of serum sickness and anaphylactic shock after injection of serum or its products has been mentioned under *Antitoxinum Diphtheriæ* (see Part I). The same precautions should be taken in the use of normal serum. Horse serum appears to be less toxic—less likely to cause serum sickness—than the serum of any other alien species, but in cases in which hypersensitiveness to horse serum is feared or proven, serum from the goat or sheep may be used. In hospitals freshly drawn rabbit serum, or whole human blood, is used for similar purposes.

No serum can be sold in interstate commerce except when produced in an establishment licensed by the Secretary of the Treasury. The requirements are those given under *Serum Antidiphthericum* U. S., except those for potency. There is no standard for the potency of normal serum.

Immune Serum. Antitoxins. Antibacterial Serums.—This term includes the serum of animals in whose blood an immunity to any given bacterium or other harmful substance has been produced by the injection of that bacterium or harmful substance. This immunity may show itself in various ways. It is most notable, and most truly an immunity when, as in the case of antitoxic immunity, the serum actually protects another animal from the toxin or poison, or even cures the second animal if injected some time after the toxin. The word *toxin* can only be applied to those poisons which have the property of inciting such an immunity (*i.e.,* producing antitoxin) when injected into an animal in gradually increasing doses. The immunity may be antibacterial instead of antitoxic, that is, attacking the bacteria themselves rather than their soluble poisons or toxins. *Antibacterial immunity* in a serum may be manifest in its bactericidal or bacteriolytic properties; these two modes of action are generally taken as synonymous, but the term bactericidal refers especially to the killing of bacteria by the serum, as shown by tests of the numbers of bacteria present after its action, while bacteriolytic has reference to the gradual breaking up and dissolving of the bacteria as seen under the microscope. Antibacterial immunity is also sometimes demonstrable as a protective action, protecting for example guinea pigs which receive the immune serum against doses of the bacterium in question which kill other guinea pigs of the same weight not receiving the serum. Antibacterial immunity may be bacteriotropic or *opsonic,* which means that the serum in question in some way changes the special bacteria so that they are easily taken up and destroyed by the white blood cells. It is to be noted that immune serums are specific—that is, if antitoxic—they neutralize only the particular toxin which was used in their preparation, and no other; if antibacterial they have an antagonistic affinity for the exact species of bacterium with which the original animal was treated, and no other, or in some cases, only closely related bacteria. This fact of specificity is made of diagnostic use in the agglutinating property of immune serums (see Widal Test for Typhoid Fever, under *Diagnostic Tests*), and in their complement fixing power (see Complement Fixation Reaction for Syphilis, under *Diagnostic Tests*).

In the case of immune serums used for the treatment of disease this specificity is frequently so high as to be detrimental. Thus an antibacterial serum prepared from a given organism may be powerless against the same species of organism arising from other sources. In meningococcus, streptococcus and pneumococcus infection this is particularly true. The organisms from different sources are called strains—and in spite of many different strains being used in the production of these serums, cases of meningitis, sepsis, or pneumonia occur in which the serums can be shown to have no influence against the infecting organism either in the body of the patient or in the laboratory. This is one of the causes of the poor success which has generally attended the use of serums other than diphtheria and tetanus antitoxin. Measures to overcome this difficulty have been taken, notably in anti-meningococcus and partially in anti-pneumococcus serum.

The material which is injected in the production of an immune serum is called the *antigen,* while the substance in the immune serum which gives rise to the different phenomena mentioned above—antitoxic, bactericidal, or bacteriolytic, protective, bacteriotropic or opsonic, agglutinative, complement fixing,—is called an *antibody.* Some workers hold that there is a different antibody for each function, while others take the view that a specific serum has only one antibody, with all these varied functions. It is certain, however, that in different serums these properties are present in different proportions, and consequently it is easier to conceive them as being exercised by different antibodies. Unfortunately, we have little means of knowing in a given case, which properties or which antibodies are the important ones in rendering a serum valuable to cure or prevent the infection in question, therefore we have no means of precisely measuring the worth of a serum.

Immune serums may be prepared against other substances than toxins and bacteria, as against foreign proteins, in which case a seventh property is apparent—that of precipitating the antigen used in its preparation. Blood cells of many other species also act as antigen for another series of immune serums; the antibody most apparent here is *hemolysin,* which dissolves the red corpuscles when added to the immune serum so that the corpuscles disappear and the fluid in which they were suspended takes on a clear red color (see Complement Fixation Reaction for Syphilis, under *Diagnostic Tests*).

All establishments manufacturing serums used in the prevention or treatment of human diseases are required to be licensed by the Secretary of the Treasury if the serums are sold in interstate commerce. Since 1918, The U. S. Treasury Department has required that Anti-dysentery serum, anti-pneumococcic serum and anti-meningococcic serum conform to certain tests for antibodies. It is required that licensed firms submit samples of every lot of those sera to the Hygienic Laboratory for examination before they are dispensed. These requirements are for all purposes potency standards for such sera. There are as yet no approved potency standards for the other sera.

Immune serums commonly contain preservatives and also are prone to cause serum sickness in the same way as diphtheria antitoxin. In this connection it is to be noted that the unofficial serums are in general distinctly less efficacious than the official antitoxins, and further that they are usually to be administered in much larger quantities if any benefit whatever is to be expected; the former consideration would cause one to hesitate if any possible danger were anticipated from their use, and the latter emphasizes the need of extreme caution unless hypersusceptibility to horse serum has been excluded.

Immune serums containing antibodies must be sharply distinguished from Vaccines (p.) which contain antigen and force the human body to manufacture its own antibodies.

All serums lose in potency rapidly at room temperatures, and there is reason to believe that toxic compounds may be found if they become frozen. Therefore they should be kept at a temperature between 4° C. and 15° C. But even with every care they gradually deteriorate and are therefore always dated with an expiration time.

Antianthrax Serum. Serum Antianthracicum. N. N. R. 1924.—This immune serum is prepared by injecting horses with gradually increasing doses of anthrax bacilli. The horses are then bled as described under normal horse serum, and the serum collected. Considerable success has attended the use of this serum in the treatment of *anthrax* in animals, and some in man, if the serum happens to be a potent one and is administered early. *Dose,* 30 cc. to 100 cc. intravenously or subcutaneously.

Antidysentery Serum. Serum Antidysentericum. N. N. R. 1924.—Certain bacilli, or groups of bacilli, have been found to be the cause of some forms of dysentery. These bacilli are classified generically as the dysentery bacillus, and are given various names, as *Shiga-Kruse* type, *Flexner* type, *Strong* type, Y type, according as their characteristics fall into one or another of these fairly well defined groups. Horses have been immunized by the injection of cultures or filtrates of one or several of these types, and the serum used in the treatment of human *dysentery.* The results in many cases have been encouraging, giving a considerable reduction in mortality over similar cases treated without serum; many observers agreeing that the use of a potent serum has reduced the mortality 30 to 50 per cent. below the usual rate. The serum has also been found of value as a prophylactic in localized outbreaks and for those in attendance on cases of the disease. Either a polyvalent serum must be used prepared by immunization with both the Shiga and Flexner types or the infecting strain determined and a corresponding type serum used. *Dose,* two and one-half to eleven fluidrachms (10–50 cc.), subcutaneously or intravenously.

Antigonococcus Serum. Serum Antigonococcicum. N. N. R. 1924.—By injection of animals with gonococci, serum may be prepared which at times shows the properties of bacteriolysis, agglutination and complement fixation. Such serum has been used in the treatment of gonococcal infections, in part with favorable results. The serum seems to have no value in acute *gonorrheal urethritis,* and the lack of complete success in other cases may be due to the failure of antibodies to reach the seat of disease in sufficient concentration.

Antimeningococcus Serum. Antimeningitis Serum. Serum Antimeningococcicum. N. N. R. 1924. —The success attending the use of this serum in cases of *meningitis* caused by the *meningococcus* (*Diplococcus intracellularis meningitidis*) is one of the great triumphs of serum therapy, second only to the success of the antitoxins against diphtheria and tetanus. To immunize the horses used in producing the serum, cultures are injected, freshly killed, living, and partially disintegrated and dissolved. A source of failure of the serum lies in the fact that there are many strains of the meningococcus, and the strain in a given case may be very different from any of those used in producing the serum; the specific antibodies fitting that particular strain would then be lacking and improvement could not be expected from the use of the serum.

A great step in advance, in the use of antimeningococcus serum, is in its application directly to the seat of disease, instead of merely subcutaneously. The injection is made under the dural membrane of the spinal canal, that is, into the meningeal space. As in other successful serum treatment, early diagnosis and early application is necessary. The injection is best done without anesthesia. The patient should be held firmly on his left side, with knees bent up nearly to the face, and with his back resting at the edge of the table or bed. The hands of the operator and the instruments must be sterilized. A stout needle with trocar at least 4 inches long should be used. The skin should be cleansed first, then treated with an antiseptic, such as tincture of iodin. The site for insertion of the needle is preferably the median line just below the fourth lumbar vertebra (on a line with the crests of the ilium). The needle is directed upward at an angle of about 35 degrees along the upper edge of the fifth lumbar spine until the point is felt to penetrate the dura, when the trocar is withdrawn and the spinal fluid allowed to flow out. This should be saved in a sterile container and examined microscopically. A turbid fluid indicates meningitis but in case of doubt it is best to inject the serum. From two to eight fluidrachms (10 to 30 cc.) of serum (previously warmed) is slowly injected by gravity pressure, the amount being best determined by the fall in blood pressure according to Sophian's method. A drop of 20 millimeters is an indication to stop the injection at once. The injection should be repeated daily until the condition of the patient has definitely improved and the spinal fluid has been free from meningococci pus cells. Some observers have reported very good results from the simultaneous intraspinal and intravenous administration of the serum, particularly where meningococci are found in the blood. It must, however, be remembered that the intraspinal injection is the most important.

The amount of preservative in serum for intraspinal administration should not exceed 0.3 per cent. cresol or phenol. If the preservative is too concentrated, or if too much serum is injected, there is danger of collapse and even death. But the danger of the disease itself is much greater and no delay in instituting serum treatment should ensue by reason of fear on this ground.

Antiplague Serum. Yersin Serum.—The horse used for immunization receives killed cultures or living avirulent cultures of *Bacillus pestis* and finally living virulent ones. It is evident that such immunization must be carried out under special precautions in view of the danger involved in working with living plague bacilli. One virulent strain appears to be as effective as another. The resulting serum can be shown to have protective action on animals, but in the treatment of human *plague* only a moderate reduction in mortality is obtained—largely because the serum is not administered at the incipiency of the disease. *Dose,* 100 cc. (three and one-third fluidounces) or more intravenously.

Antipneumococcus Serum. Serum Antipneumococcicum. N. N. R. 1924.—The pneumococcus (*Diplococcus pneumoniæ,* Weichselbaum) is present more often than any other organism as a causative factor in pneumonia. In one or more of its types it is found in about 60 per cent. of normal mouths or throats and is often associated with ordinary colds, severe grip-like infection, middle ear disease, ulcer of the eye, or meningitis. Serums have repeatedly been produced by immunizing animals against the pneumococcus but the results have been variable. Römer, Neufeld, and Cole and others have conducted experimental investigations in serum therapy of pneumonia; it appears to be one requisite for success that the serum be produced by the use of the type of pneumococcus found in the patient to be treated. Certain of these types are more frequent than others and offer more promise. Other desiderata are that the serum be used early —on the first or second day of the disease if possible, and that large amounts—as much as 100 cc. per dose—be injected intravenously. At present the serum treatment of *pneumonia* is practically confined to the type I infection for which alone does the Treasury Department provide a standard. To be of any value the serum must be given early, in large doses intravenously and limited to Type I infections.

Antistreptococcus Serum. Serum Antistreptococcicum. N. N. R. 1924.—Many attempts have been made to produce therapeutically valuable antistreptococcus serum. In many commercial serums some antagonistic influence on streptococci can be demonstrated in the laboratory, but only rarely are authentic series of benefited cases reported. It seems to be necessary to introduce a large amount of the serum (100 cc. or more) intravenously, and in such a serious disease as streptococcus infection the added strain on the eliminative mechanism caused by such quantities of foreign protein may turn the tide in the wrong direction. The Viennese reports of success with streptococcus serum therapy in severe cases of *scarlet fever* have not been confirmed in this country. The strong serum specificity of different strains of the bacterium may account for divergent results. The activity of antistreptococcus serum appears to be largely bacteriotropic.

Antivenomous Serums. Antivenins.—The snake poisons are true toxins and the serums prepared to combat them are true antitoxins. Theoretically, then, we should expect the excellent results of diphtheria and tetanus antitoxin to be duplicated in the serum treatment of *snake bites,* instead of the equivocal results of the antibacterial serums. Certain practical difficulties have interfered with such success. In the first place, the toxins of snake venoms are highly specific. Not only are there present in a given venom several different poisons, such as *hemorrhagins* (causing breaks in the blood-vessels and consequent hemorrhages), *neurotoxin* (poisoning the vital center of the central nervous system), *coagulins* (causing clotting of the circulating blood), *hemolysins* (destroying the red blood cells), *hemoglutinins* (clumping the red blood cells)—but each of these is peculiar to its own species. Therefore to be effective, the serum must be derived from an animal immunized against the particular species of snake to be encountered. In the second place, very potent serums have not as yet been prepared—due largely to the difficulty in securing the antigen, snake venom—in large quantities. Thirdly, the serum must be on hand and used immediately.

In the case of the common North American poisonous snakes,—the rattlesnake, copperhead, and watermoccasin, hemorrhagins are the most important toxins. If antivenomous serums are available they should be carried by the traveller and administered within a few minutes after the bite. Some time may be saved by the ligature cutting off the return flow of blood from the part affected. 100 cc. or more of the antivenomous serum suited to the species of snake concerned should be injected intravenously, and more injected intramuscularly in the vicinity of the wound.

Sesamum. *Sesamum indicum* L. (Fam. *Pedaliaceæ.*)—The *benne* plant is a native of Asia but has become naturalized in our Southern States and is cultivated in all parts of the tropical world. It is an annual, with a branching stem 1 to 2 feet high, and bearing opposite (lower), or alternate (upper), petiolate leaves, varying considerably in their shape. The flowers are pale rose or white, and stand singly upon short peduncles in the axils of the leaves. The fruit is an oblong capsule, with small, oval, yellowish-white, brown, reddish or black seeds.

There are about twenty species referred to the genus *Sesamum,* the majority of which are natives of Africa. In India one or two species occur wild; one of these, *Sesamum indicum* L. (*S. orientale* L.), has been cultivated from time immemorial in various parts of Asia and Africa. From the latter continent it is supposed that seeds were brought by the negroes to the United States, where, as well as in the West Indies, it is now cultivated to a considerable extent. The plant above described will grow as far north as Philadelphia. The seeds are employed as food by the negroes, who parch them over the fire, boil them in broths, make them into puddings, and prepare them in various other modes. By expression they yield a fixed oil, which is recognized by the N. F. (See *Oleum Sesami,* Part I.) Berjot obtained from the seeds 53 per cent. of oil by means of carbon disulphide. Rautenberg reported a series of severe poisonings from the intestinal injection of sesame oil. (*J. A. M. A.*, xlvii, p. 1962.) These accidents, he believes, are due to adulteration of the oil.

Benne Leaves.—These abound in a gummy matter, which they readily impart to water, forming a rich, bland mucilage, much used in the Southern

States as a drink in various complaints to which demulcents are applicable, as in *diarrhea, dysentery, catarrh, acute cystitis, strangury,* etc. One or two fresh leaves of full size, stirred about in half a pint of cool water, will soon render it sufficiently viscid. With dried leaves hot water is used. The leaves also serve for the preparation of emollient cataplasms.

Sethia. *Sethia acuminata* Arn. (now *Erythroxylon lucidum* H. B. K.) (Fam. *Erythroxylaceæ.*)—The juice of this Ceylon plant or the powdered leaves—*dose,* fifteen grains (1.0 Gm.)—are affirmed to be an efficient vermifuge. (*P. J.*, April 7, 1883.)

Sida. *Sida rhombifolia* L. *Mesbé. Queensland-hemp. Jelly-leaf.* (Fam. *Malvaceæ.*)—The leaves of this shrubby plant are largely used in Australia as a demulcent. They contain a large quantity of mucilage. The fluidextract has been asserted to possess expectorant properties and to be especially valuable in the treatment of *pulmonary tuberculosis.* Zink (*M. M. W.*, 1912), however, was unable to obtain evidence of any specific action in *tuberculosis. Sida paniculata* L. (*S. floribunda* H. B. K.), of Peru, which also contains a large quantity of mucilage, is said by Martinet to be an active vermifuge, owing its powers, probably, to the extremely minute but very resisting spines which cover its leaves, the part used.

Siegesbeckia. *Siegesbeckia orientalis* L. (Fam. *Compositæ*).—This plant is used in the Mauritius Islands in *syphilis, leprosy,* and various skin diseases. A white, crystalline principle, *darutine,* has been discovered in it by M. L. Auffray. (*P. J.*, vol. xvi, 1047; also *B. M. J.*, June 25, 1887.)

Sienna. *Terra di Sienna.*—An argillaceous mineral, compact, of a fine texture, very light, smooth, and glossy, of a yellowish-brown or coffee color, leaving a dull orange trace when moistened and drawn over paper. By calcination it assumes a reddish-brown color, and is then called *burnt sienna.* In both the raw and burnt states it is used in painting. The best *sienna* is brought from Italy, but an inferior kind is found in England.

Silene. *Silene virginica* L. (Fam. *Caryophyllaceæ*). *Fire Pink. Catchfly. Wild Pink.*—This perennial herb, native to open woods from Western New York to Minnesota and southward, was considered by the Indians poisonous and by Barton an anthelmintic. It is a slender herb having thin-spatulate or oblong-lanceolate leaves and deep crimson or scarlet flowers in a loose cyme.

Silex, Pulverized. *Silex Contritus* Lond. *Quartz.*—For mechanical purposes, in the making of aromatic waters, etc., the London Pharmacopœia formerly recognized under the name of *Silex Contritus* powdered *quartz;* but at present powdered purified talc, paper pulp and kieselguhr are employed. For details, see 17th edition, *U. S. D.*, p. 1741.

Pulverized silex is a harsh, white, tasteless powder, insoluble in water and most other solvents. Its sp. gr. is 2.66. In composition it is a *silicic oxide,* SiO_2.

Silicon, Si. 28.3, is an electro-negative element, which has been obtained in two allotropic states, called amorphous and crystalline silicon; the first corresponding to amorphous carbon having a sp. gr. of 2.00 and the second to crystallized carbon or the diamond, except that it is steel-gray in color. The second variety is hard enough to scratch glass but not topaz and has the sp. gr. 2.49. It is now made on a large scale as a product of the electric furnace, being used as a deoxidizing agent in the casting of some metals. Pure *silica* is easily prepared by acidulating commercial solution of sodium silicate with hydrochloric acid, heating and evaporating, and washing the precipitated silica. In recent years *silicic acid* and other compounds of silicon have attracted some attention in the treatment of *pulmonary tuberculosis.* Klare and Budde (*M. M. W.*, 1922, lxix, p. 741) used a tetraglycol ester of silicic acid which is marketed under the trade name of *silicitrin.* It is a colorless sweetish fluids representing 18 to 20 per cent. of SiO_2. They gave it in doses of ten drops several times a day.

Silk Peptone.—This is a preparation of peptone derived from silk and standardized to a nearly uniform optical rotatory powder. It is a white to a yellowish non-hygroscopic powder, easily soluble in water and used as a testing agent for peptolytic ferments in tissues or in stomach contents. It has no use in therapy.

Silphium. *Silphium laciniatum* L. *Polar Plant.* (Fam. *Compositæ.*)—The *rosin weed,* or *compass plant,* of Ohio, yields an oleoresin, which is said to be used in making chewing gum. (*A. J. P.*, 1881, 487.)

Silver Acetate. *Argenti Acetas.* $AgC_2H_3O_2$.—*Silver acetate* occurs in white crystals, or a white crystalline powder, soluble in about 90 parts of water at ordinary temperatures, more soluble in hot water. It has been introduced by Zweifel (*Centralbl. f. Gynækologie,* 1900, No. 51) as a substitute for silver nitrate in the treatment of *ophthalmia* of new-born infants. He asserts that the one per cent. solution is in these cases much more effective than the older salt.

Silver Albumoids. *Protein Silver Salts. Silver Proteinates.*—A large number of compounds of silver with various protein derivatives have been brought forward for use in local infections, especially of the mucous membranes. As there is a strong similarity in the chemical properties and therapeutic uses of these compounds it has seemed advisable to consider them in one group. The peculiar properties, both chemical and therapeutic, that characterize this group of compounds have been described under *Argenti Proteinum,* Part I. See also *Silver, Soluble.*

Albargin. Silver Gelatose.—This substance, which is a compound of silver nitrate with gelatose, is a yellowish, shining, sometimes coarse powder which, in either cold or warm water, freely forms neutral dialyzable solutions. It contains 14.8 to 15 per cent. of silver. It is incompatible with tannin and chlorides which precipitate gelatose and silver, respectively. It affects albumin slowly and also precipitates cocaine solutions, but may be used with the alkaloid providing the double solution be freshly prepared at the time of administration. It is not quickly reduced by light, but should be preserved in amber-colored bottles. Another compound of silver and gelatin is known as *Gelargin.*

Albargin was introduced by Bornemann (*Ther. Geg.*, March, 1901) for the treatment of *gonorrhea.* When there is much irritation, the 0.1 per cent. aqueous solution may be injected four or five times a day; in more chronic conditions the solution may be up to 2 per cent.

Argaldin.—This is stated to be a compound of silver, albumin and hexamethylenamin and to contain 8.9 per cent. of silver. It is employed in strengths of 10 per cent.

Argonin. Silver Caseinate. Argentum Casein.—This is a white powder, of neutral reaction, prepared by mixing equivalent quantities of solutions of sodium caseinate and silver nitrate and precipitating with alcohol. It contains 4.28 per cent. of silver and forms opalescent faintly alkaline solutions in water. It is incompatible with acids and acid salts, but is not affected by chlorides. A 10 per cent. solution in warm water is said to be permanent in the dark. (A. Leibrecht, *Th. M.*, vii, 1895.) It has been highly recommended by both German and American clinicians in the treatment of acute and chronic cases of *gonorrhea.* Its 10 per cent. solution causes no pain in acute *gonorrhea.* According, however, to the elaborate study of H. M. Christian, it is not of much service in the treatment of *posterior urethritis.* One hundred and sixty minims (10 cc.) of a 2½ to 3 per cent. solution may, in the acute stages of the disease, be injected into the urethra and allowed to remain there for five minutes. A solution—0.3 ammonia water, 0.6 argonin, 100 of water—is said by R. Mayer to be much more powerful than argonin itself.

Argyn. N. N. R. 1924.—A colloidal form of silver oxide with serum albumin which contains from 25 to 30 per cent. of silver in a form not readily ionizable. It occurs as black, lustrous, hygroscopic granules which readily form colloidal solutions with either water or glycerine but not with alcohol. It is not precipitated by sodium chloride or albumin. It is recommended as a germicide in strengths of 10 to 25 per cent.

Argyrol. Silver Vitellin. Argentic Vitellin. N. N. R. 1917.—This substance is said to be a combination of silver with a protein produced by the electrolysis of serum albumin. It occurs as brownish-black hygroscopic scales, freely soluble in water or glycerine but not in alcohol. It gives a slight cloudiness with sodium chlorides.

Argyrol has been used chiefly in the treatment of *conjunctivitis* and *urethritis*, especially of the gonorrheal type.

Argyrol belongs to the group of silver protein compounds containing very little ionic silver. Although its chemical constitution is not known with certainty, it is generally believed to represent a colloidal silver oxide, the protein acting only as a colloid protective.

Argyrol has been used chiefly in the treatment of infections of the mucous membranes, such as *conjunctivitis, urethritis, rhinitis,* etc. It is practically free from any local irritating or astringent effect. The statements concerning the antiseptic powers of this compound have varied so greatly that one is driven to the conclusion that the substance at present sold under this name is not the same as that originally introduced under this name. The older tests show that its disinfectant powers were very slight; Post and Nicoll (*J. A. M. A.*, 1910, lv) for example, found that a 50 per cent. solution was not certainly germicidal even with thirty minutes' exposure. Culver (*J. Lab. Clin. M.*, 1918, iii, 487) more recently has found that it is an active germicide, one-half of 1 per cent. destroying the gonococcus in 5 minutes' exposure. Lancaster (*B. M. S. J.*, 1920, lxxxiii, 565) finds that 1 per cent. is antiseptic and 10 per cent. slowly germicidal. Some clinicians have attributed its beneficial effect to other than antibacterial properties; it has been suggested that its therapeutic virtue is at least in part owing to the power of dissolving pus and mucus and hence acting as a mechanical cleanser.

Solutions of argyrol, when kept, not only lose their germicidal power, as has been shown by Culver and others, but apparently also develop irritant properties.

It is one of the least irritant of all the silver preparations, and may be used in the urethra in strengths of from 1 to 10 per cent., while in *gonorrheal ophthalmia* it has been employed in concentrations up to 30 per cent.

The stains of argyrol may be readily removed from either skin or clothing by solution of chlorinated soda.

Largin. Silver Protalbin.—This is a compound of silver and protalbin, which occurs as a whitish powder, soluble in water to the extent of 10.5 per cent., freely soluble in glycerin, blood serum, and peptone solution. Not precipitated by chlorides nor yet by albumin, and containing 11.1 per cent. of silver. In brown bottles it keeps unchanged indefinitely. It is astringent as well as germicidal. In male *gonorrhea* the strength of the injection should be one-fourth of one per cent., gradually increased up to two per cent. In women the parts may be irrigated with from a one-half to one per cent. solution, after which a 5 per cent. largin bougie may be held in position by a cotton plug for fifteen minutes and the part again irrigated with a 0.5 per cent. solution of largin. Largin is also largely used in the treatment of infectious *conjunctivitis* and catarrhal *corneal ulcers* in the form of gelatin tablets containing one per cent.

Lunosol. Colloidal Silver Chloride. Argenti Chloridum Colloidale Saccharatum, N. N. R., 1925.—This preparation is claimed to have the advantages of being not only a powerful and penetrating germicide, but especially that it does not stain. It is easily soluble in water, forming dichroic opalescent solutions, and is said to be non-irritant and is used, in strengths of from 3 to 25 per cent., in the treatment of *urethritis, conjunctivitis,* etc.

Novargan. Silver Proteinate.—This occurs as a yellow, amorphous powder, freely soluble in water, yielding a neutral solution. It is asserted that the silver from this solution is not precipitated either by chlorides, sulphides, alkalies, or by any of the substances that ordinarily precipitate silver or its salts from solutions. The compound represents 10 per cent. of silver.

Novargan is actively astringent and also bactericidal. In *gonorrhea* it is used in strengths of from 0.5 to 5 per cent. according to the acuteness of the inflammation. According to Von Hoessle and Grater (*D. M. Ztg.*, 1905, p. 92) it is less irritating to the mucous membranes than protargol and has also the advantage of a deeper penetration. Regenspurger (*Med. Klin.*, 1908, No. 8) has used it for the abortion of *gonorrhea* in the following manner. After washing out the urethra he injects 8 to 12 cc. of a solution containing five parts of novargan and ten parts of glycerin and water to make one hundred which is allowed to remain in the urethra for from five to fifteen minutes. If no inflammatory reaction follows this twenty-four hours later he injects a 10 per cent. solution. He claims that a very considerable number of cases with this treatment are cured within a period of eight days.

Proganol. N. N. R. 1924.—A compound of silver and albumose containing a little over 8 per cent. of silver. It is recommended that in making solutions of this salt a small quantity of cold water be mixed with it and stirred to a thick paste and then the remaining water be added gradually with stirring. It is employed usually in strengths of from 0.25 to 5 per cent.

Protargentum. N. N. R. 1924.—It is a chocolate-colored powder, odorless, freely though slowly soluble in water yielding solutions which are alkaline to litmus but neutral to phenolphthalein. It is insoluble in alcohol. Protargentum contains approximately 8 per cent. of silver. It is usually employed in strengths of from ½ to 5 per cent. solution, which should be freshly prepared.

Protargol. N. N. R. 1924. *Protargolum. Protein Silver Salt.*—A combination of silver and albumin, containing about 8 per cent. of metallic silver. It occurs as a yellow powder, soluble in 1 part of water, the solution not being affected by heat, albumin, hydrochloric acid, weak sodium chloride solution or sodium hydroxide solution. The dry salt as well as the solution should be protected from light.

According to the experiments of Kelly (*B. M. J.*, 1907, ii, p. 1475), silver nitrate is nearly 300 times as powerful a germicide as protargol, and in the experiments of Post and Nicoll (*J. A. M. A.*, 1910, lv, p. 1635) a ten per cent. solution of protargol was inferior to a one-tenth per cent. solution of silver nitrate. On the other hand, Derby (*B. M. S. J.*, cxlv, p. 341) found that *Staphylococcus aureus* was killed by a two to four per cent. solution of protargol in three to five minutes. It is evident that in germicidal power, protargol is far inferior to silver nitrate. It is claimed, however, that it has greater penetrating power, and that it can be used much stronger, because of its relative slight irritant properties. As to the first of these claims, Derby has shown that the presence of blood serum interferes with the activity of protargol, as well as all other preparations of silver, and both Kelly and Marshall and Neave (*B. M. J.*, 1906, ii, p. 350) assert that the penetrating power of silver nitrate into agar-agar is not greatly inferior to the protein compound of silver. As to the second claim that protargol is less irritant in proportion to its germicidal power, the data concerning its antibacterial properties are so contradictory that it is impossible to state categorically whether, in strengths of similar irritation, silver nitrate or protargol is the more efficient germicide.

Protargol has been used very extensively, especially in *gonococcus infections* either of the urethra or conjunctiva. In *acute urethritis* it may be used in strengths of from 0.5 to 2 per cent. for injections, and has been used in 10 per cent. strength for the so-called abortive treatment. In *ophthalmia neonatorum*, Speiro (*M. M. W.*, 1909) drops a 10 per cent. protargol solution into the conjunctival sac, once or twice daily, while, according to Cogwill (*D. M. Ztg.*, 1904) the strength may at times be increased to as high as 30 per cent. in this condition. Protargol has also been used as a germicide for various other conditions. Berliner (*M. M. W.*, 1908) has found it useful in the treatment of *acute tonsillitis*, and it has also been employed as a surgical antiseptic in suppurating *ulcers, carbuncles* and the like.

Silvol. N. N. R. 1924.—This compound, which is said to contain 20 per cent. of silver, resembles argyrol in its physical and, it is asserted also, its therapeutic uses. It is freely soluble in water forming dark-colored solutions with relatively high specific gravity and low viscosity. According to the experiments of Culver (*J. Lab. Clin. Med.*, 1918, iii, 487) silvol is more actively germicidal than argyrol, one part in 3000 killing gonococci in thirty minutes and 0.5 per cent. in less than one minute. The report of the Council on Pharmacy and Chemistry (*J. A. M. A.*, 1918, lxxi, 138) shows that the 10 per cent. solution is non-irritant to the nasal mucous membrane, does not yield a precipitate with the chlorides but, under certain conditions, may yield a precipitate with egg albumin. The claim is made for this preparation in that in addition to its germicidal power it is astringent. It is used in strengths of from 5 to 25 per cent.

Under the name of *Neo-silvol, N. N. R.* 1924, a compound of silvol with an iodide has been introduced. It contains from 18 to 22 per cent. of silver iodide in a colloidal state. The advantage claimed for this preparation is that while it possesses all the therapeutic virtues of its parent it is free from staining properties. It occurs as pale yellow granules which form a milky emulsion when mixed with water. It is used in strengths of from 5 to 40 per cent.

Although solutions of Neo-silvol are actively germicidal they sometimes develop a mold on standing; they therefore should not be kept for more than a few days.

Vargol. N. N. R. 1924.—This contains 20 per cent. of silver combined with albumin. It occurs as greenish-black, lustrous scales, very hygroscopic, easily soluble in water. Its solutions are not affected by sodium chloride, iodide or hydroxide. It is used in strengths of from 10 to 25 per cent., and is said to resemble argyrol in its field of usefulness.

Silver Ammonio-chloride. *Argenti Ammonii-chloridum. Argentum Chlorato-ammoniatum.*—This substance is formed by saturating solution of ammonia, by the aid of heat, with silver chloride and allowing the liquid to cool in a stoppered bottle. It crystallizes in cubes. Silver ammonio-chloride has been used in the treatment of *chorea, epilepsy,* and *syphilis,* and as an anthelmintic, in *doses* of from one-twelfth to one and a half grains (0.005–0.1 Gm.). It is probably of little value.

Silver Arsphenamine. *N. N. R.* 1924. *Silver Salvarsan. Silver Diarsenol.*—The exact molecular formula of this compound has not been established but it is the sodium salt of silver diaminodihydroxy-arseno-benzene containing approximately 20 per cent. of arsenic and 15 per cent. of silver. It is recommended in the treatment of *syphilis* as a substitute for arsphenamine. It has been claimed for it that not only is the spirocheticide effect of the arsenical compound enhanced by the silver but that it is less prone to produce toxic symptoms in the patient. Dyer and Voegtlin (*J. P. Ex. T.*, 1921, xvii, 329) have found, from experiments on the lower animals, that while the tolerated dose is 25 per cent. smaller than that of arsphenamine, the trypanocidal dose is only one-third that of the older compound; in other words, the ratio of therapeutic to toxic dose is much more favorable for the silver salt. Walson (*Am. J. M. S.*, 1921, clxi, 418) from review of the literature and his own employment of the drug in 800 patients comes to the conclusion that it is less dangerous and, at least equally efficacious with arsphenamine. He states that in 100,000 reported injections there has been no deaths attributable to the drug. Strauss (*J. A. M. A.*, 1922, lxxviii,

632) on the other hand finds it decidedly inferior to arsphenamine.

Solutions of silver arsphenamine deteriorate rapidly when exposed to the air and must be freshly prepared at the time of use. The same precautions must be observed as in the use of arsphenamine. The dose recommended is from 0.1 to 0.3 Gm. (one and one-half to five grains) at intervals of one-half to three days.

Silver Atoxylate. *Argenti Atoxylas. Argatoxyl.* $NH_2C_6H_4As.O.AgO.OH$.—*Silver atoxylate* (*atoxylic silver*) is insoluble in water, and is the monosilver salt of para-amino-phenylarsonic acid. According to Blumenthal, atoxylate of silver contains 23 per cent. of arsenic and 33 per cent. of silver. Silver atoxylate has been used chiefly to increase bodily resistance in infectious diseases. According to Rosenstein (*All. M. C.*, 1912) its beneficial effects are due in part to its bactericidal properties and in part to a leukocytosis which it calls forth. It has been used in *puerperal septicemia, rheumatic fever, gonorrheal arthritis, scarlet fever, carbuncles,* and other infections. From five to six grains (0.3–0.4 Gm.) suspended in ten times as much olive oil may be injected intramuscularly at intervals of from one to several days. The injections are often followed by abscess formation but it is stated that the abscesses formed are sterile.

Silver Chloride. *Argenti Chloridum.* AgCl.—This is readily prepared by adding a solution of sodium chloride to one of silver nitrate, as long as it produces a precipitate. As first thrown down, it is a white, curdy substance, but it soon becomes discolored when exposed to the light. It is decomposed by solutions of the caustic alkalies, which convert it into oxide, but not by their carbonates. It is practically insoluble in water but is dissolved by solutions of the cyanides. Silver chloride has been used in *syphilis, epilepsy, chronic dysentery* and *diarrhea,* and other diseases in which silver nitrate has been given, but is probably of no value. The *dose* is from one to two grains or more (0.065–0.13 Gm.), four or five times a day.

Silver Citrate. $Ag_3C_6H_5O_7$. *N. N. R.* 1924. *Itrol.*—An odorless heavy powder which is moderately sensitive to light. It contains not less than 62 per cent. of metallic silver. This salt, which is almost insoluble in water, was introduced by Credé as a dusting powder for wounds. It is powerfully antiseptic and non-irritant. According to Marshall and Neave (*B. M. J.*, 1906, ii) it is a more powerful germicide than silver nitrate. It has been very highly recommended by Werler (*Derm. Zeit.*, vol. cxi) in the treatment of *urethritis,* as being a powerful gonococcocide and non-irritant to the mucous membrane. He employs a solution varying in strength from one part in four thousand to one in eight thousand, which is to be injected four times a day. Von Arlt (*Aerzt. Zentral-Zeit.*, 1905) employs it in various infectious conditions of the eye, such as gonorrheal *ophthalmia, trachoma* and the like. His method of using it is to dust the powder on the previously cleansed conjunctiva, and to rinse off after a few minutes, either with water or borax solution. Warler also commends it as a remedy in the treatment of chronic *cystitis.* Tilger and other surgeons have commended the remedy in the treatment of all forms of infected mucous membrane in saturated solution (1 in 3800). Pfonarlt (*W. M. W.*, 1908, No. 52) recommends the dusting of the conjunctiva with pure itrol in cases of *ophthalmia neonatorum, trachoma,* and other severe infections of the eyes, alleging that it is no more irritant than would be any insoluble foreign body. In using silver citrate, it should be remembered that it is easily decomposed, especially in the presence of organic matter, and should be kept well stoppered and protected from the light.

Silver Cyanide. *Argenti Cyanidum, U. S. VIII.*—This salt was formerly official for the purpose of preparing extemporaneously hydrocyanic acid through decomposition with diluted hydrochloric acid. It is never used as a medicine. Silver cyanide is a white powder insoluble in water or alcohol, but soluble in solution of the cyanides. It is permanent in the air if protected from light, but becomes brownish on exposure to light.

Silver Fluoride. *Tachiol. Argenti Fluoridum.* AgF = 126.88.—Mueller (*D. M. W.*, 1908) recommends this salt as an injection in *gonorrhea* in strengths of from 1 in 10,000 to 1 in 2000. Stronger solutions, he says, are locally irritant. The silver fluoride, as well as the *silver silicofluoride* (*isotachiol*), Ag_2SiF_6, have been suggested for the purpose of sterilizing drinking water. According to the experiments of Hetsch 5 Gm. per 1000 liters will destroy most of the bacteria, but when these were numerous 10 Gm. per 1000 liters are not sufficient, and the agent is therefore not suitable for this purpose.

Silver Iodate. $AgIO_3$.—This is a white insoluble powder. It is used chiefly as antiseptic in various *catarrhs,* especially in *enteritis* and *gastritis.* The *dose* is from one-twelfth to one-sixth of a grain (0.005–0.01 Gm.).

Silver Iodide. *Argenti Iodidum. U. S.* 1890. AgI = 234.80.—This salt may be readily prepared by adding a solution of potassium iodide to one of silver nitrate, and washing and drying the precipitate, which should be kept in dark amber-colored vials, protected from light. This iodide is said to have three allotropic forms and a point of maximum density at about 116° C. (See paper by G. F. Rodwell, in *Chem. News,* xx, 288; xxi, 14.) The U. S. Pharmacopœia, 1890, described it as "a heavy, amorphous, light yellowish powder, unaltered by light, if pure, but generally becoming somewhat greenish-yellow, and having neither odor nor taste. Insoluble in water, alcohol, diluted acids, or in solution of ammonium carbonate, but soluble in about 2500 parts of stronger ammonia water. It is also dissolved by an aqueous solution of potassium cyanide, and by a concentrated solution of potassium iodide, and the resulting solutions yield a black precipitate with hydrogen sulphide test-solution or ammonium sulphide test-solution. When heated to about 400° C., the salt melts to a dark red liquid, which, on cooling, congeals to a soft, yellow, slightly transparent mass. When mixed with ammonia water, it turns white, but regains its yellowish color upon being washed with water. If a small quantity of chlorine water be agitated with an excess of the salt, the filtrate acquires a dark blue color on the addition of starch test-solution." *U. S.*, 1890.

Silver iodide in suspension has been recommended as an injection for gonorrheal *urethritis* by Siter and Uhle. For this purpose, it is generally prepared extemporaneously. The formula recommended by Wilbert (*A. J. P.*, 1906) is 2.2 Gm. of silver nitrate dissolved in 50 cc. of mucilage of acacia and 45 cc. of water and to this is added 2.2 Gm. of potassium iodide which is dissolved in 50 cc. of water and thoroughly shaken. Such a suspension of silver iodide is marketed as *Silvodide.* J. C. and B. L. DeG. Peacock (*Proc. Penna. Pharm. Assn.*, 1916, p. 231) contribute a thorough review of the various methods for preparing this emulsion and conclude that mucilage of chondrus is the best suspending medium when thoroughly purified. For tests of purity, see *U. S. D.*, 19th ed., p. 1647. Silver iodide has been given in *doses* of one or two grains (0.065–0.13 Gm.) three times a day, in *epilepsy* and other chronic nervous diseases, but is devoid of value.

Silver Hexamethylenetetramine.—Two preparations asserted to contain a compound of silver with hexamethylenetetramine are known respectively as *argotropin* and *argaldon* (*D. M. W.*, 1922, xlviii, p. 696). They are used as local antiseptics.

Silver Lactate. *N. N. R.* 1924. *Argenti Lactas. Actol.* $AgC_3H_5O_3 + H_2O$.—*Silver lactate* was introduced by Credé as a surgical germicide. It is affirmed that its injection renders an infected wound rapidly aseptic without much irritation. It is soluble in 20 parts of water, and may be used in very strong, even saturated, solution. D. A. Tilger finds that the application of the pure powder to the curetted infected sore causes only moderate burning pain of short duration and acts most happily. (*M. M. W.*, 1897.) Its therapeutic properties seem to be purely local, since E. Marx found that after injection of very large doses of it into animals it does not prevent the development of pathogenetic germs. It is almost certainly decomposed at the point of injection, but, unlike silver nitrate, it does not form an insoluble compound when brought in contact with tissues, and so is able to find its way through these tissues. Fifteen grains (1 Gm.) of it have been given hypodermically without more serious symptoms than some burning pain at the point of injection. According to Marx, a remarkable rise of temperature follows the use of it in very large doses. Under the proprietary name actol has been used to a considerable extent in dentistry, decayed or decaying pulp being washed with a solution of the strength of 1 in 2000 and then dusted with itrol.

Silver Methylene Blue. *Argochrome.*—This silver salt occurs as a blue powder readily soluble in water and representing 20 per cent. of silver. According to Edelmann (*D. M. W.*, 1913, p. 2292) it is germicidal in strengths of 1 part in 160,000 and contrary to many other antibacterials, exercises a considerable disinfectant power in the blood, 1 part in 80,000 exhibiting a distinctly antiseptic action. Doses of 0.1 Gm. per kilo injected subcutaneously produce no toxic effects in rabbits. It has been used not only as a local application, but as an internal disinfectant in *septicemia, rheumatic fever* and other infectious diseases. (See Leschke, *B. K. W.*, 1920, lvii, 79.) The *dose* recommended is from one to four grains (0.06–0.25 Gm.), either subcutaneously or intramuscularly. Leschke has also reported favorable results in endocarditis streptococcus pneumonia from a *silver trypaflavin* (*argoflavin*), used intravenously in doses of approximately three-quarters of a grain (0.05 Gm.).

Silver Methylene-nucleinate. *Sophol. Silver formo-nucleinate.*—This is a dark yellow, tasteless, odorless powder, readily soluble in water. When heated it gives off formaldehyde, a residue of metallic silver being left behind. Its solutions are not stable. It contains 20 per cent. of silver.

Sophol is asserted to possess a powerful germicidal action without any irritant effect upon mucous membranes. According to Vollert (*Ther. Neu.*, July, 1906), a 0.37 per cent. solution of sophol is bacteriologically equivalent to a 1 per cent. of protargol. It has been used chiefly in ophthalmic conditions, especially *gonorrheal ophthalmia* and also in non-specific cases of *conjunctivitis* in strengths of from 5 to 10 per cent. While apparently of much value for the purpose of destroying bacteria located on the superficies of the conjunctiva, Dreser (*A. J. P.*, xviii) states that it is lacking in penetrating power and is less valuable than silver nitrate after the germs have passed through the epithelium.

The solutions should be freshly prepared, as on standing, formaldehyde is liberated which is likely to prove irritant.

Silver Nitrate Ammonia Albumose. *Hegonon.*—It is asserted to contain approximately 7 per cent. of silver organically combined. It is not precipitated by albumin or sodium chloride.

Hegonon has been employed as an antiseptic in *gonorrhea* by Klingmuller. (*M. M. W.*, 1910.) It may be used in strengths of 1 in 400 to 1 in 3000.

Under the title *Argentamin* there is on the market an 8 per cent. solution of silver nitrate in a 15 per cent. aqueous solution of ethylene diamine. It is a clear, strongly alkaline liquid, sp. gr. 0.97, which does not precipitate albumin or chlorides. On exposure to air it is liable to turn yellow, but can be cleared by filtration. Its use in medicine was proposed in 1894 by Jean Schaeffer. (*Zeitsch., f. Hyg. u. Infektions*, 1894, xvi, Bd. ii.) Hoor used it in a large number of eye cases; he asserts that it causes less pain and irritation than the silver nitrate, and penetrates deeper. He used a 5 per cent. solution in the eye from one to four times a day in the same cases as those in which silver nitrate is useful. According to Aschner (*Orv. hetil.*, 1895), it is well borne by the posterior urethra in as strong solution as 1 to 250; but the anterior urethra will not bear more than 1 to 2000. An aqueous solution containing 10 per cent. of argentamin with 30 per cent. of a 1 per cent. solution potassium bichromate has been used instead of silver nitrate as a stain for histological examination of the nerve tissues. (*Ph. Ztg.*, 1910, No. 43, 436.)

Silver Orthophosphate. *Silver Phosphate. Normal Silver Phosphate. Argenti Phosphas.* $Ag_3(PO_4)$.—This substance is prepared by dissolving silver in concentrated orthophosphoric acid; the vitreous mass which results, while still melted, is dissolved in water acidulated with phosphoric acid, yielding a permanent solution. Normal silver phosphate is a yellow, odorless, powder very sparingly soluble in water but more soluble in the presence of phosphoric acid. Spretzka (*Rév. Med. Pharm.*, v, 292) asserts that it is a valuable remedy in *gonorrhea.* The injection should contain 0.025 to 0.05 per cent. of the salt, increasing gradually to 0.25 or even 0.5 per cent.

Silver Oxide. *Argenti Oxidum. U. S. IX. Argentum Oxydatum, Argentic Oxide; Oxyde d'Argent*, Fr.; *Silberoxyd*, G. $AgO_2 = 231.76$.—Silver oxide was dismissed from the British Pharmacopœia (1914), and from the U. S. P. at the tenth revision.

In the processes for making it, silver nitrate is decomposed by potassium hydroxide or lime, the oxide being precipitated, and potassium nitrate or calcium nitrate, as the case may be, remaining in solution. When thus obtained, the oxide is an olive-brown powder. It was officially described as follows: "Silver Oxide is a heavy, dark brownish-black powder, easily reduced by exposure to light; odorless, and having a metallic taste. Silver Oxide is very slightly soluble in water, to which, however, it imparts an alkaline reaction; insoluble in alcohol; it is dissolved by nitric acid. When heated in a porcelain crucible to about 250° to 300° C., Silver Oxide is rapidly decomposed, with the evolution of oxygen, leaving a residue of metallic silver. Dissolve about 0.2 Gm. of the Oxide in a mixture of 1 cc. of nitric acid and 2 cc. of distilled water, add 10 cc. of ammonia water and dilute the liquid to 60 cc.; 10 cc. of this solution does not immediately become cloudy upon the addition of 1 cc. of nitric acid (*chloride*). A solution of the Oxide in nitric acid is colorless, and responds to the tests for identity and purity under *Argenti Nitras* when the tests are applied to a solution of proportionate strength.

"*Assay.*—Dissolve about 0.5 Gm. of Silver Oxide, previously dried to constant weight at 120° C. and accurately weighed, in 3 cc. of nitric acid and 50 cc. of distilled water in a flask, add 2 cc. of ferric ammonium sulphate T.S. and titrate the mixture with tenth-normal potassium sulphocyanate V.S. It shows, in the dried Silver Oxide, not less than 99.6 per cent. of Ag_2O. Each cc. of tenth-normal potassium sulphocyanate V.S. used corresponds to 0.011588 Gm. of Ag_2O. Each gramme of Silver Oxide, dried to constant weight, corresponds to not less than 86.0 cc. of tenth-normal potassium sulphocyanate V.S." *U. S. VIII.*

When its solution in nitric acid is precipitated by sodium chloride in excess, the supernatant liquid is not discolored by ammonium sulphide. It parts with its oxygen with great facility, being decomposed by many organic substances; in this way it causes sulphur, amorphous phosphorus, or tannin to take fire when rubbed with it, in a mortar. It should be kept in "well-stoppered, dark amber-colored vials. It must not be triturated with readily oxidizable or combustible substances, and must not be brought in contact with ammonia." *U. S. IX.*

If pills are ordered they should not be made with honey, confection of rose, or other excipient containing glucose; and, indeed most organic substances, especially in a moist state, deoxidize the oxide, reviving the silver. A case is recorded in which pills containing it exploded violently in the pocket of the patient. (See Jackson, *P. J.*, xi, 552.) An ointment from five to ten grains to the drachm, has been used as an application to *venereal sores*, and to the urethral membrane in *gonorrhea;* it should be smeared on a bougie.

Dose, one grain (0.065 Gm.).

Silver Phenolsulphonate. *Argenti Phenolsulphonas. Silver Sulphocarbolate. Silberol.* $C_6H_4(OH)SO_3Ag$.—A crystalline powder containing 28 per cent. of metallic silver, soluble in water; proved to undergo spontaneous decomposition, but said to be more permanent than itrol. Originally introduced by Zanardi as having the antiseptic properties without the corrosive action of silver nitrate, silberol has been employed by various practitioners in the treatment of *gonorrhea* and *ophthalmic inflammations*, and as a germicide in ocular surgery. It is asserted that a 2 per cent. solution is well borne as an antiseptic after operations upon the eye; also that when it is used as a substitute for silver nitrate silberol must be employed in twice as concentrated solution.

Silver Picrate. *Silver Tri-nitro-phenylate. Picratol.* $C_6H_2O(NO_2)_3Ag + H_2O$.—This occurs as yellowish crystals and is said to represent 30 per cent. of silver. It is soluble in 50 parts of water. It is used as an antiseptic in *gonorrhea* and other *catarrhs* in strengths of from one-half to two per cent.

Silver Quinaseptolate. *Argenti Quinaseptolas. Argentol.* $C_9H_5N.OHSO_3Ag$.—This substance is a yellow powder, sparingly soluble in water, which was introduced into medicine by Credé on account of its readily splitting up into oxyquinoline and metallic silver. Both septic matters and intestinal juices are said to produce this change. It has been employed either as a dusting powder or in the form of spray, or injection, 1 in 300 to 1000, in *chancres, gonorrheas*, and various other surgical infections. C. Cipriani asserts that it is a valuable intestinal antiseptic of which 15 grains (1 Gm.) may be given safely in the twenty-four hours if necessary. It is said also to be an active non-irritant antiseptic with marked hemostatic properties.

Silver, Soluble. *Argentum Solubile. Argentum Colloidale. Soluble Silver. Colloidal Silver.*—Several allotropic modifications of silver were discovered by Carey Lea in 1891. One of these has been introduced into medicine. "Soluble Silver," so-called, can be prepared by taking a mixture of 30 Gm. ferrous sulphate dissolved in 100 cc. of water and 36 Gm. of crystallized sodium citrate dissolved in 140 cc. of water and pouring this mixture with stirring into 100 cc. of a 10 per cent. silver nitrate solution. After allowing the precipitate to settle, the supernatant liquid is poured off, the precipitate dissolved in water, and again precipitated with absolute alcohol. When dried, the colloidal silver is a bluish or green-colored mass, which dissolves in water with a deep red color, but is precipitated from its solution by the addition of salt solutions. It contains 97.2 per cent. silver. The commercial preparations of colloidal silver usually contain some other protective colloid, such as a protein, and consequently vary considerably in their proportion of silver.

There are at present two forms of so-called colloidal or soluble silver employed in medicine, one of which is prepared by chemical means, and the other by electrolytic methods. The manufacturers of the latter preparations claim that the therapeutic virtues of the electrically prepared colloidal silver are much more clearly established than those of the chemically prepared varieties.

Colloidal silver was introduced into medicine by Credé with the idea that it would possess the germicidal properties of silver, and being non-toxic, might be used internally for the control of various bacterial infections. It has been used very extensively in the treatment of *septicemia, rheumatic fever, gonorrheal arthritis, diphtheria, cerebro-spinal meningitis*, and other infectious diseases. While a large number of clinicians have been enthusiastic in their praises of its efficacy, there is as yet no well-supported theory of its mode of action, and a number of careful observers have denied that it possesses any therapeutic virtues whatsoever. Whatever may be the real value of this remedy, it is evident that it does not act as Credé had expected, as an antiseptic in the blood. In the first place, Brunner has shown that its germicidal action is extremely feeble, and Cohn (*K. T. W.*, 1905) found that within forty-five minutes after its injection the silver had disappeared from the blood entirely. This same observer has stated further that it had neither prophylactic nor curative properties in rabbits, against infection with the staphylococci. On the other hand Dunger (*M. M. W.*, 1907) found that its injection leads to pronounced leukocytosis, and his conclusions have received considerable confirmation.

As has been stated elsewhere (see *Colloids*) the intravenous injection of metallic hydrosols may produce reactions similar to those following the parenteral absorption of foreign proteins and in this way increase the body resistance to bacteria.

While the germicidal power of colloidal silver is too low to explain any possible benefit from its systemic use a number of the preparations of this type are sufficiently active antibacterials to be of use as local agents in the treatment of *rhinitis, conjunctivitis, urethritis,* etc. Their range of usefulness is practically that of the silver proteinates.

The most widely used preparations of colloidal silver are as follows:

Choleval.—In this colloidal silver preparation sodium cholate acts as the protective colloid. Choleval occurs as a brownish-black, lustrous powder, easily soluble in water, containing 10 per cent. of silver. It is asserted to be actively germicidal and is used as a local application in various infectious conditions of strengths of from 0.25 to 1 per cent.

Collargol. N. N. R. 1923. *Collargolum. Argentum Credé.*—A colloidal form of silver and silver oxide stabilized by egg albumen and containing nearly 80 per cent. of metallic silver. This occurs in bluish-black scale-like pieces which, with 20 parts of distilled water, yield a brownish colloidal solution which is permanent if protected from light and heat. It is asserted to represent over 80 per cent. of metallic silver. It may be injected intravenously in solutions of from 2 to 5 per cent. strength, administering an amount of the solution equivalent to one to five grains (0.065–0.32 Gm.) once or twice a day. It is also widely employed in the form of a 15 per cent. ointment, *Unguentum Credé,* of which one-half to one drachm (1.8–3.75 Gm.) is applied at a *dose,* being vigorously rubbed into the skin.

Electrargol is marketed in bottles and in sealed tubes. The *dose* is eighty to one hundred and sixty minims (5–10 cc.) injected intramuscularly or directly into a vein.

Cargentos. N. N. R. 1924.—This is a *colloidal silver oxide,* which is said to represent 50 per cent. of metallic silver.

Lysargin.—A colloidal silver containing 60 per cent. of the metal. It forms steel blue lustrous scales, forming a brilliant brownish solution when dissolved in water. Solutions of *lysargin* are stable in the air, do not stain, are not affected by daylight, but are decomposed in direct sunlight. Possessing antiseptic value it is used as an injection in *gonorrhea* in 0.5 to 1 per cent. solution.

Argoferment is a colloidal silver preparation manufactured by an electrolytic process.

Collene.—This colloidal solution is said to represent 5 milligrammes of silver per cc. Ransohoff (*Am. Med.*, 1921, xvi, 20) has found that it is an active germicide and has used it successfully in a variety of local infections. Another advantage claimed for it is that its solutions are stable.

Dispargen.—In this colloidal preparation a decomposition product of glutin is used as the protective colloid. When dried it contains 30 per cent. of silver. It is injected, for its systemic effect, in doses of 0.04–0.1 Gm. (two-thirds to one and a half grains).

Solargentum. N. N. R. 1924.—A compound of gelatin with silver in the colloidal form containing from 19 to 23 per cent. of silver. It occurs as black, lustrous, non-hygroscopic scales, freely soluble in water, insoluble in oils or alcohol. It is used in strengths of 1 to 25 per cent. in various local inflammations.

Synthargol.—This colloidal silver is asserted to be destructive to both *Staphylococci* and *Streptococci* in 0.5 per cent. strengths in one minute. It is recommended by Gobbi (*Schweiz. Med. Woch.*, 1922, lxii, 617) as a wound disinfectant.

Silver Sodium Thiosulphate. *Sodium and Silver Thiosulphate. Sodii et Argenti Thiosulphas.*—This double salt may be prepared by dissolving freshly precipitated silver oxide in a solution of sodium thiosulphate and evaporating the solution. It is in the form of minute crystals of the formula $2Na_2S_2O_3 + Ag_2S_2O_3$, very soluble in water, but insoluble in alcohol, and possessing a sweet taste. Its solution, protected from the light, undergoes no change, and, when quite pure, does not discolor the skin or linen. Delioux states that this salt acts locally like silver nitrate, but more mildly: for *gonorrhea,* one or two parts in two hundred of water may be used.

Silver Thiohydrocarburo-sulphonate. *Argenti Thiohydrocarburo-sulphonas. Silver Sulphoichthyolate. Silver Ichthyol. Ichthargan.*—This compound of ichthyol-sulphonic acid and silver is a brown amorphous stable powder, freely soluble in water, glycerin and diluted alcohol, insoluble in alcohol, ether, and chloroform. Its aqueous solution blackens with exposure to light, and in concentrated solution it is precipitated by sodium chloride and by albumin, the albuminous precipitate being redissolved by an excess of albumin. It is said to contain about 30 per cent. of silver and 15 per cent. of sulphur.

Wood (*N. Y. M. J.*, 1903, lxxvii) found that, although ichthargan is much less poisonous, its physiological action is the same as that of silver nitrate. The germicidal power of ichthargan is certainly equal, and probably superior, to that of silver nitrate, and it is far less irritant. It is therefore, a very valuable remedy for local application in the treatment of various infectious conditions, especially those involving mucous membranes. In *tonsillitis* and *pharyngitis* it may be applied to the throat with a swab in strengths of from 5 to 10 per cent. In *urethritis* for injections, solutions of 1 to 500 to 1 in 3000 may be used; for irrigations from 1 in 2000, to 1 in 5000.

Unna (*Med. Klin.*, 1913) highly recommends the use of ichthargan in various *skin diseases,* especially *psoriasis* and *chronic eczema.* He uses an ointment varying in strength from 5 to 15 per cent.

In *eczema, ulcerations, phlegmons,* and in *lymphangitis,* the ointment varying from 1 to 15 per cent. is advised, well rubbed into the adjacent healthy skin, previously thoroughly cleansed, and also applied directly to the affected surface, if it be exposed. Ichthargan has also been administered internally with asserted excellent results for the relief of *gastritis* and especially of *gastric ulcer. Dose,* one-twentieth to one-eighth of a grain (0.003–0.008 Gm.) in half a fluidounce (15 cc.) of water, on an empty stomach.

Simaruba. *Orinoco Simaruba. Surinam Simaruba. Ecorce de simarouba,* Fr. *Simarubarinde, Ruhrrinde,* G. *Corteccia di Simaruba,* It. *Corteza de Simaruba,* Sp. (Fam. *Simarubaceæ.*)—The U. S. 1870 recognized the root-bark of the *Simaruba amara* Aubl. (*S. officinalis* DC.). This is a tree of considerable height, having alternate branches, with a bark which in the old tree is black and somewhat furrowed, in the young is smooth, gray, and marked here and there with broad yellow spots. It is a native of French Guiana and the West Indies Islands.

Simaruba bark is in long pieces, from 4 to 12 cm. wide and 2 to 6 mm. thick, folded lengthwise, light, flexible, tenacious, very fibrous, externally of a light brownish-yellow color, rough, warty, and marked with transverse ridges longitudinally rent, inner surface yellowish and longitudinally wrinkled with projecting fibers, internally of a pale yellow. It is without odor, and of a bitter taste. It readily imparts its virtues, at ordinary temperatures, to water and alcohol. The infusion is at least equally bitter with the decoction, which becomes turbid as it cools. Its constituents, according to Morin, are a bitter principle to which Gilling (*P. J.*, 1908, lxxxi) ascribes the formula, $C_{22}H_{30}PO_9$, a resinous matter, a volatile oil having the odor of benzoin, malic acid, gallic acid in very minute proportion, an ammoniacal salt, calcium malate and oxalate, some mineral salts, ferric oxide, silica, ulmin, and lignin.

A closely related species, having, however, diœcious instead of monœcious flowers, flourishes in Jamaica, San Domingo, Bahama Islands, Panama and Guatemala, extending even to Florida; it is called in Jamaica *mountain damson,* and is known as *S. glauca* DC. (*S. officinalis* Macf., not DC.) The two species have probably identical medicinal properties. The bark of the root is the part employed, the wood being nearly tasteless and inert. The middle bark contains much resin. A decoction of the bark and leaves of *S. versicolor* St.-Hil. (*Cortex Paraibæ*), is employed in Brazil as an antidote for snakebites and in the treatment of *syphilis* and *tapeworm;* the powder is used against vermin.

Simaruba possesses the same tonic properties as other simple bitters. In large doses it is said to purge and vomit. On account of its difficult pulverization, it is seldom given in substance. The best mode of administration is by infusion. The *dose* is from twenty grains to a drachm (1.3–3.9 Gm.).

Simulo.—The dried fruit of *Capparis coriacea* Burch., one of the *Capparidaceæ,* has been recommended as a palliative in *epilepsy;* also in *chorea.* (See *T. G.*, 1888, 1889; and *Th. M.*, Aug., 1888.)

Sisymbrium. *Sisymbrium officinale* (L.) Scop. *Hedge Mustard. Herbe aux chantres, Tortelle,* Fr. *Wildersenf, Hederich,* G. (Fam. *Cruciferæ.*)—This small, yellow-flowered annual, growing in Europe and in waste grounds in the United States, is said to be diuretic and expectorant and has been recommended in chronic *coughs, hoarseness,* and ulceration of the mouth and fauces. The juice of the plant may be used mixed with honey or sugar, or the seeds may be taken in substance.

Sisymbrium Sophia L., or the *flax weed,* a plant which grows sparingly in waste places in the United States, was formerly official. It is of a pungent odor when rubbed, and of an acrid, biting taste. W. Zopf attributes its poisonous qualities to a volatile alkaloid. (*Zeit. f. Nat. Pharm. Central.*, 1894, 494.) The herb has been used externally in *indolent ulcers* and the seeds internally in *worms,* calculous complaints, etc.

Diplotaxis muralis DC., (*S. Murale* L.), a plant growing about Atlantic ports, was formerly used in France in *scurvy, scrofula,* and other cachectic affections, especially associated, in the form of a syrup, with potassium iodide. Grazing sheep are said to be killed in Southern France by feeding on *Diplotaxis tenuifolia* DC., and human poisoning has occurred. This species is also sparingly naturalized like *D. muralis.* George Heyl has separated a toxic and apparently uncrystallizable alkaloid. (*Ap. Ztg.*, May 30, 1900.)

Sium.—*Sium cicutæfolium* Schrank. *Water Parsnip* (Fam. *Umbelliferæ*), which grows in British America and the United States, particularly along the water courses of the valleys of the Pacific slope, is asserted to be poisonous. A. R. Porter and N. Rogers (*A. J. P.*, 1876, 348, 483) found in it an active resinous body, toxic to animals. A volatile oil is stated by Rabak to be found in the plant in the proportion of 0.5 per cent. It is yellow and has an odor resembling that of caraway. (*Mid. Druggist,* 1905, 5.) *S. Sisarum* L., or *skirret,* a plant of Chinese origin, cultivated in Europe, has a sweetish, aromatic root. The latter is used in much the same manner as the oyster plant and parsnip. It is supposed to be a useful diet in chest complaints.

Skimmia. *Skimmia japonica* Thunb. *Miramashikimi.* (Fam. *Rutaceæ.*)—From this dwarf-growing, holly-like Japanese shrub, which is cultivated on account of its dark, shining, evergreen leaves and clusters of bright-red berries, Eykman separated a glucoside, *skimmin,* and a decomposition product, *skimmetin.* (*Abhandl. d. Tokyo Diagaku.*, No. 10, Tokyo, 1883.) J. Honda (*A. E. P. P.*, Oct., 1904), however, finds that the activity of the plant depends upon the presence of the crystalline alkaloid, *skimmianine* $C_{32}H_{29}O_9N_3$. It is a muscle poison, producing no primary excitement in the muscle, but an increasing paralysis, the influence of the alkaloid extending to involuntary muscles, such as the heart, so that in mammals arterial pressure is progressively decreased.

Skin Varnishes.—Unna at one time proposed a series of preparations for forming thin coverings on the skin. Among these were, *Bassorin Varnish, Casein Varnish, Castor oil and Shellac Varnish,* etc., Formulas for these and other skin varnishes may be found in the *U. S. D.*, 20th edition, p. 1611.

Smalt. *Smalts. Azure.*—When the impure *cobaltic oxide,* obtained by roasting the native arsenide of that metal, is heated with sand and potassium hydroxide, the mixture melts, and a beautiful blue glass results, which, when reduced to powder, forms smalt or azure. It is used chiefly in painting, and for coloring glass and porcelain.

Sodium Bisulphite. *Sodii Bisulphis. U. S. VIII. Sodium Hydrogen Sulphite. Acid Sodium Sulphite. Leucogen. Sulfite (Bi) de Soude,* Fr. Cod. *Natrium Bisulfurosum. Doppeltschwefligsaures Natron,* G. $NaHSO_3 = 104.08$.—*Sodium bisulphite* is prepared by thoroughly saturating a concentrated solution of sodium carbonate or bicarbonate with sulphurous acid gas, and collecting the crystals which form upon the cooling of the liquid. As found in commerce, it usually contains sodium thiosulphate and sulphate, and is not reliable; even when kept in well-stoppered bottles it will readily lose its crystalline character and the quantity of sulphurous acid gradually diminishes. The bisulphite, under the technical name of leucogen, was formerly largely used in many industries. It served as bleaching agent in washing wool, and in the steeping of grain, and in preserving meats and vegetable juices, because of its reducing and antifermentative character. Its use as a preservative for foods is illegal.

It was officially described as in "opaque, prismatic crystals, or a granular powder, exhaling an odor of sulphur dioxide, and having a disagreeable, sulphurous taste. Exposed to the air, the salt loses sulphur dioxide, and is gradually oxidized to sulphate. Soluble in 3.5 parts of water, and in 70 parts of alcohol at 25° C.; in about 2 parts of boiling water, and in 49 parts of boiling alcohol. When strongly heated, the salt decrepitates, emits vapors of sulphur and of sulphur dioxide, and leaves a residue of sodium sulphate. To a non-luminous flame it imparts an intense yellow color. Its aqueous solution gives an acid reaction with blue litmus paper. On the addition of hydrochloric or sulphuric acid, an aqueous solution of the salt evolves sulphur dioxide, which is recognized by its odor, and by its blackening a strip of paper dipped into mercurous nitrate T.S. and held over the escaping gas." *U. S. VIII.* For further tests for this salt see *U. S. D.*, 20th ed., p. 1612.

This salt possesses germicidal properties, which the neutral salt does not, due to the liberation of sulphurous acid. It is used as an antiseptic in *gastric fermentation* and externally in parasitic *skin diseases. Dose,* five to ten grains (0.32–0.65 Gm.).

An analogous compound employed for similar purposes is *sodium metabisulphite,* $Na_2SO_3.SO_2$.-$Na_2S_2O_5$. It is an acid salt and is also known as *sodium pyrosulphite* and *sodium anhydrosulphite.*

Sodium Boro-Salicylate. *Sodii Boro-salicylas.* —This is made by heating 125 parts of boric acid, 320 parts of sodium salicylate, and 700 parts of water in a flask until a syrupy liquid is produced; this solidifies on cooling, yielding a white product. It dissolves in water. It is used as an antiseptic and preservative.

Sodium Chlorate. *Sodii Chloras. U. S. VIII. Natrium Chloricum. Chlorate de Soude,* Fr. Cod. *Chlorsaures Natron,* G. *Clorato sodico,* Sp. $NaClO_3 = 106.46$.—"It should contain not less than 99 per cent. of pure Sodium Chlorate [ClO_2.-ONa]. This salt should be kept in well-stoppered bottles, and *great caution should be observed* in handling it, as dangerous explosions are liable to occur when it is heated, or subjected to concussion or trituration with organic substances (cork, tannic acid, sugar, etc.), or with sulphur, antimony sulphide, phosphorus, or other easily oxidizable substances." *U. S. VIII.*

It occurs in "colorless, transparent crystals (principally cubes with tetrahedral facets), or a crystalline powder; odorless, and having a cooling, saline taste. Permanent in dry air. Soluble in about 1 part of water, and in about 100 parts of alcohol at 25° C.; in 0.5 part of boiling water, and in about 40 parts of boiling alcohol; also soluble in about 5 parts of glycerin. When heated, the salt melts, then gives off oxygen (about 45 per cent. of its weight), and finally leaves a residue of sodium chloride." *U. S. VIII.*

Sodium chlorate has medicinal properties similar to those of potassium chlorate, while its greater solubility permits the use of stronger solutions. According to Brissaud, when given in daily doses of more than two drachms it is apt to produce albuminuria. In overdose it would probably cause symptoms not distinguishable from those caused by potassium chlorate poisoning. *Dose,* five to fifteen grains (0.32–1.0 Gm.

Sodium Cyanide. *Sodii Cyanidum U. S. IX.*—"It contains not less than 95 per cent. of NaCN (49.01). Preserve it in well-closed containers, protected from light." *U. S. IX.*

This salt, which was dismissed in the tenth revision of the U. S. P., may be made by various processes. One of the most recent methods is by the fusion of calcium cyanide with sodium carbonate, $Ca(CN)_2 + Na_2CO_3 = 2NaCN + CaCO_3$.

It has the advantage over the potassium salt of being somewhat less prone to absorb moisture.

It was officially described as occurring "in the form of white, opaque, amorphous pieces, or as a white, granular powder; odorless when perfectly dry; deliquescent in the air and exhaling the odor of hydrocyanic acid. *Great caution must be used in handling this salt.* It is freely soluble in cold water. An aqueous solution of the salt (1 in 20) is strongly alkaline to litmus and emits the odor of hydrocyanic acid. At a low red heat the salt fuses. To a non-luminous flame it imparts an intensely yellow color. A few drops of a solution of the salt (1 in 20) yield with silver nitrate T.S. a white precipitate, which is soluble in an excess of the solution of Sodium Cyanide, and in ammonia water. Shake 5 mils of a solution of the salt (1 in 20) with a few drops each of ferrous sulphate T.S. and of ferric chloride T.S., and then add a slight excess of hydrochloric acid; a blue precipitate (iron ferrocyanide) is produced. In 5 mils of an aqueous solution of the salt (1 in 10) a drop of ferric chloride T.S., followed by 2 mils of diluted hydrochloric acid produces neither a dark blue color (*ferrocyanide*) nor a red color (*sulphocyanate*).

"*Assay.*—Dissolve about 0.45 Gm. of Sodium Cyanide, accurately weighed, in 25 mils of distilled water, add 4 mils of ammonia water, 3 drops of potassium iodide T.S. and titrate with tenth-normal silver nitrate V.S. to the production of a permanent precipitate. It shows not less than 95 per cent. of NaCN.

"Each mil of tenth-normal silver nitrate V.S. used corresponds to 0.009802 Gm. of NaCN. Each gramme of Sodium Cyanide corresponds to not less than 96.9 mils of tenth-normal silver nitrate V.S." *U. S. IX.*

Sodium cyanide acts upon the system as does prussic acid. (See *Acidum Hydrocyanicum Dilutum.*) It is rarely used as a medicine. Sodium cyanide has the power of dissolving silver oxide and may be used for the removal of silver nitrate stains from clothing. According to Guthrie, a solution of three grains (0.2 Gm.) to the ounce (30 cc.), dropped in the eye every other day, will remove olive colored stains from the conjunctiva caused by silver nitrate. Five grains of it may be regarded as a usual fatal dose (see Venghauss, *A. Pharm.*, clii, p. 138), although smaller doses may occasionally take life.

Owing to the large use of the cyanides for the recovery of gold and other technical purposes, numerous accidental cases of poisoning have occurred. The symptoms and treatment of these are precisely the same as outlined under *Acidum Hydrocyanicum.*

Dose, one-eighth of a grain (0.008 Gm.).

For further tests see *U. S. D.,* 20th ed., p. 1613.

Sodium Dithiosalicylate. $S(C_6H_3(OH)COONa)_2$. *Dithion I* and *II.*—These are two isomeric salts separable by means of sodium chloride solution, the dithion I being insoluble in the latter solution. Dithion I is a yellowish-white, amorphous, soluble powder employed mostly in veterinary practice as a dusting powder of antiseptic value. The dithion II is used like sodium salicylate as an antirheumatic and antipyretic, free, it is said, from secondary action. *Dose,* thirty to sixty grains (2–4 Gm.).

Sodium Ethylate. *Sodii Ethylas. Ethylate of Sodium. Caustic Alcohol.* C_2H_5ONa.—This preparation was introduced by B. W. Richardson of England, as a caustic. He made it by adding sodium in small pieces gradually to absolute alcohol, kept at a temperature of 10° C.; hydrogen is evolved, and when, owing to the formation of the ethylate, the reaction slackens, the liquid is to be carefully heated to 37.7° C. Sodium is then cautiously added until the reaction ceases; the liquid is cooled to 10° C., and the same quantity of absolute alcohol added as was used in the beginning. (*P. J.,* 1878, 485.) *Sodium ethylate* is a white powder, frequently having a brownish tinge, dissolving in water with a hissing sound, having the property of splitting into alcohol and sodium hydroxide upon contact with even a small quantity of water or moist living tissue:

$$C_2H_5ONa + H_2O = C_2H_5OH + NaOH$$

Sodium ethylate does not appear to be of any value as an internal remedy. When, however, it comes in contact with moist tissue, owing to the liberation of its sodium, it acts as a very speedy and powerful caustic. It should always be used in alcoholic solution, and applied by means of a glass rod. It is said to cause very little pain (*L. L.,* Nov., 1878.) A *solution of sodium ethylate* was official in the Br., 1898, under the title *Liquor Sodii Ethylatis.* It was prepared as follows: "Sodium, clean and bright, 22 *grains* (Imperial) or 1 gramme; Absolute Alcohol, 1 *fl. ounce* (Imp. meas.) or 20 cc. Cautiously dissolve the Sodium in the Absolute Alcohol contained in a flask, the latter being kept cool by a stream of cold water." *Br.,* 1898.

It is described as "a colorless liquid of syrupy consistence, becoming brown by keeping. Specific gravity 0.867. When slightly heated it boils and gives off alcoholic vapors, leaving a white residue which, on being strongly heated, becomes charred. If the white residue be mixed with *water* and heated, it yields ethylic alcohol, and the solution, on evaporation, leaves a white residue consisting almost wholly of caustic soda. This solution should be recently prepared. It contains 18 per cent. of the solid substance, C_2H_5ONa." *Br.,* 1898. Gamberini and Monari (*R. T.,* 1892) assert that the 20 per cent. liniment made with olive oil, well rubbed in daily, will usually cure *psoriasis* in twenty days, and that the 10 per cent. aqueous solution is very valuable in the treatment of *lupus erythematosus,* applied after curetting.

Sodium Formate. *Sodii Formas. Ameisensaures Natrium,* G. $HCO_2Na + 2H_2O$.—Prepared by neutralizing formic acid with sodium carbonate. It occurs in colorless, rhombic prisms, which are inodorous, and have a saline, bitter taste. Sodium formate is very deliquescent and dissolves freely in water. For account of therapeutic properties see *Formic Acid. Dose,* one-half to three grains (0.032–0.2 Gm.).

Sodium Lactate. $CH_3CHOHCOONa$.—Prepared by interaction between lactic acid and sodium carbonate. It is so extremely hygroscopic that its preservation in solid form is impossible. It occurs as a colorless or yellowish syrupy liquid, neutral or slightly alkaline and having a mild saline taste, containing about 70 to 75 per cent. of the salt.

According to Curatolo (*Il Policlinico,* 1920, xxvii, 1482) sodium lactate is oxidized in the body with the production of a carbonate, with exceptional readiness. It therefore offers a useful means of alkalizing the system in cases of *acidosis.* He has employed it with especially favorable results in the treatment of acetonemia of *diabetes.* He gives it in doses of from three to eight drachms (10–30 Gm.) in a day.

Sodium Metaborate. *Antipyonin.* $NaBo_2 + H_2O$.—*Sodium metaborate* is made by boiling borax and boric acid in water. It is also erroneously called *sodium tetraborate.* It occurs as a fine, white powder, greasy to the touch, freely soluble in water. This salt is non-poisonous, devoid of caustic action, and markedly antiseptic. It is probably therapeutically equivalent to borax, but has been especially recommended in a 2 to 50 per cent. solution, or blown in as a powder, by Jaenicke and by Kafemann in *acute* and *chronic otorrhea.* Roland attributes extraordinary effects to its insufflation in *keratitis, conjunctivitis,* and other inflammatory eye conditions.

Sodium Methyl Arsenate. *Di-sodium Methyl Arsenate. Sodii Methylarsenas.* ($OAsCH_3O_2Na_2 + 5H_2O$.)—This arsenic preparation occurs as a crystalline powder containing 27.37 per cent. arsenic, easily soluble in water and less so in alcohol. It is precipitated by alkaloids; with mercuric chloride it gives a reddish precipitate, and with copper sulphate a green precipitate. It appears to be about equivalent in its physiological and therapeutic effects to sodium cacodylate (see Part I), over which the advantage is claimed that it does not impart a garlicky odor to the breath that is characteristic of the cacodylates. The *dose* is from one-third to one grain (0.021–0.065 Gm.). It is also sold under various trade names, as *arrhenal, arsynal, neoarsycodile, stenosine,* etc.

Sodium Naphthol. *Naphthol Sodium.—β-Naphthol sodium* (*microcidine*), a white powder easily soluble in water, used as a non-caustic, non-poisonous antiseptic, said to be much stronger than phenol.

Sodium Nitrate. *Sodii Nitras. U. S. VIII. Nitrate of Soda. Soda Nitre. Cubic Nitre. Chili Saltpeter. Nitras (Azotas) Sodicus. Nitrum Cubicum. Azoate de Soude,* Fr. Cod. *Natriumnitrat,* G. *Nitrato di sodio,* It. $NaNO_3 = 85.01$.—This salt is imported from South America, where it is found naturally, especially in the desert of Atacama, forming beds of vast extent. The nitrate deposits have been found uniformly through a zone 250 geographical miles in length north to south, and two geographical miles in width east to west. It was estimated that the nitrate beds contained the enormous quantity of 99,031,525 tons. The salt has been found also largely in

Brazil, in the province of Bahia, near the river San Francisco. For an account of the sodium nitrate deposits of Chili, see *Potassii Nitras.* The crude salt is in saline lumps, rather soft and friable, and damp on the surface. Its varieties are classified, according to their color and state of aggregation.

"*Caliche,*" as the crude mineral is called, contains from 48 to 75 per cent. of sodium nitrate, from 20 to 40 per cent. of sodium chloride, and smaller amounts of sodium sulphate, calcium sulphate, potassium nitrate, and potassium and sodium iodate (from 0.059 to 0.175 per cent. of iodine). Occasionally calcium borate, associated with sodium borate, is found under the beds of the nitrate.

Sodium nitrate, when pure, is in "colorless, transparent, rhombohedral crystals, odorless, and having a cooling, saline, and slightly bitter taste. Hygroscopic in moist air. Soluble in about 1.1 parts of water, and in about 100 parts of alcohol at 25° C.; in 0.6 part of boiling water, and 40 parts of boiling alcohol. When heated to 312° C., the salt melts without decomposition. At a higher temperature it evolves oxygen, and is reduced to nitrite. This salt has been praised as a remedy in *dysentery* (see 15th ed., *U. S. D.*), in the *dose* of from half an ounce to an ounce (15.5–31 Gm.) in the course of the day in dilute solution, but is at present very rarely, if ever, used in practical medicine.

Sodium Nitroferrocyanide. *Sodium Nitroprusside. Sodii Nitroferrocyanidum.* $Na_2Fe(CN)_5NO. + 2H_2O$.—This is one of the interesting series of salts, discovered by Playfair, called *nitroprussides,* which are produced, for the most part, by saturating *nitroferrocyanic acid,* formed by the action of nitric acid in potassium ferrocyanide, with different bases. For method of preparation see *U. S. D.*, 20th ed., p. 1614. The salt is in the form of large, ruby-colored, prismatic crystals, resembling those of potassium ferricyanide. It is soluble in two and a half parts of cold water, and in less quantity of hot water. Its solution, exposed to sunshine, is decomposed, with evolution of nitric oxide gas, and deposition of Prussian blue, at the same time acquiring a green color. Sodium nitroprusside, as well as the other soluble nitroprussides, is a most delicate test for alkaline sulphides, with which it produces a violet color. It is used also as a test for acetone in urine (see *Diagnostic Tests*) and in several tests for the detection of formaldehyde.

Sodium Oleate. *Sodii Oleas. Eunatrol.—Sodium oleate* may be made by dissolving 10 parts of sodium hydroxide in alcohol and adding the solution to 100 parts of oleic acid and carefully evaporating the soap which is formed to dryness. It is a whitish mass or a white powder. It dissolves in about 10 parts of water with partial decomposition, the solution thereby acquiring an alkaline reaction. The so-called *acid sodium oleate* is a mixture of this soap with free oleic acid. Sodium oleate was at one time believed to be useful in cases of *gall stone. Dose,* from fifteen to forty grains (0.9–2.6 Gm.) daily in capsules.

Sodium Phenolsulphonate. *Sodii Phenolsulphonas. U. S. IX. Sodii Sulphocarbolas, Br.,* 1898. *Sodium Sulphocarbolate. Sodium Sulphophenylate. Sodium paraphenol-sulphonate. Sodium Sulphophenate. Sulfophenate de Soude,* Fr.; *Phenolsulfosaures Natrium, Phenylschwefelsaures Natron,* G.—"It contains not less than 83.64 per cent. nor more than 87.82 per cent. of anhydrous sodium phenolsulphonate (sodium paraphenolsulphonate), corresponding to not less than 99 per cent. of the crystallized salt [$NaC_6H_5O.SO_3 + 2H_2O = 232.14$]. Preserve it in well-closed containers." *U. S. IX.*

"Sodium Phenolsulphonate occurs as colorless, transparent, rhombic prisms or crystalline granules; odorless, and having a cooling, saline, bitter taste. It is somewhat efflorescent in dry air. One Gm. of Sodium Phenolsulphonate dissolves in 4.2 mils of water, 140 mils of alcohol and in about 5 mils of glycerin at 25° C.; also in 0.8 mils of boiling water and 13.5 mils of boiling alcohol. An aqueous solution of Sodium Phenolsulphonate (1 in 10) is neutral to litmus. When heated slightly above 100° C. the salt loses all of its water of crystallization and becomes white. At a higher temperature it chars, emits inflammable vapors having the odor of phenol, and finally leaves a residue consisting chiefly of sodium sulphate. To a non-luminous flame it imparts an intensely yellow color. A diluted solution of the salt (1 in 100) is rendered pale violet by ferric chloride T.S., but remains clear; barium chloride T.S. leaves the solution of the original salt clear, but if the salt is ignited, and the residue dissolved in distilled water, the same reagent produces in the filtered solution a copious, white precipitate. Add bromine T.S. to 10 mils of an aqueous solution of the salt (1 in 100); a permanent yellow color but neither turbidity nor precipitation is produced within two minutes (*phenol*). An aqueous solution of the salt does not respond to the Test for heavy metals.

"*Assay.*—Dissolve about 0.25 Gm. of Sodium Phenolsulphonate, accurately weighed, in 50 mils of distilled water, add 50 mils of tenth-normal bromine V.S. and 5 mils of hydrochloric acid. Allow the mixture to stand for fifteen minutes, then add 2 Gm. of potassium iodide dissolved in 5 mils of distilled water, and subject the solution to residual titration with tenth-normal sodium thiosulphate V.S., using starch T.S. as indicator. It shows not less than 83.64 per cent. nor more than 87.82 per cent. of $NaC_6H_5O_4S$.

"Each mil of tenth-normal bromine V.S. used corresponds to 0.004903 Gm. of $NaC_6H_5O_4S$. Each gramme of Sodium Phenolsulphonate corresponds to not less than 170.6 mils nor more than 179.1 mils of tenth-normal bromine V.S." *U. S. IX.*

The phenol sulphonates, or sulphocarbolates as they are commonly called, were introduced into medicine with the idea of obtaining the antiseptic action of carbolic acid in a non-toxic form, for it is well known that the combination of sulphuric acid with phenol destroys its toxicity. But it has been shown by Withers that the phenol sulphonates are not possessed of any antiseptic power. The claim which has been made that they are decomposed in the intestinal tract with the liberation of phenol is not supported by any scientific evidence and seems *a priori* improbable. There is neither sufficient clinical nor scientific evidence of the value of this drug in medicine. Sodium phenolsulphonate is, however, still employed as an intestinal antiseptic.

Dose, five to ten grains (0.32–0.65 Gm.).

Sodium Pyrophosphate. *Sodii Pyrophosphas. U. S. VIII. Natrium Pyrophosphoricum. Pyrophosphate de Soude,* Fr. Cod. *Pirofosfato sodico,* Sp. $Na_4P_2O_7 + 10H_2O = 446.24$.—This salt which was recognized by the U. S. VIII is prepared by heating sodium phosphate in a suitable vessel to redness. When sodium phosphate is subjected to a temperature of 44° C., it melts in its water of crystallization; if the heat be increased to 100° C., all the water will be expelled, and but 40 per cent. of the original weight remain; at 300° C. it is converted into the tetrabasic phosphate or pyrophosphate. By dissolving this residue in water, filtering and crystallizing, the salt may be obtained.

It occurs in "colorless, transparent, monoclinic prisms, or a crystalline powder; odorless, and having a cooling, saline, and feebly alkaline taste; slightly efflorescent in warm air. Soluble in about 11.5 parts of water at 25° C., and in 1.1 parts of boiling water; insoluble in alcohol. When heated to 100° C., the salt loses its water of crystallization (40.35 per cent.) without previous fusion. At a higher temperature it fuses, forming a transparent liquid, which, on cooling, solidifies to a crystalline mass." *U. S. VIII.* An aqueous solution is feebly alkaline to litmus and to phenolphthalein. It may be distinguished from the orthophosphates by the facts that it gives a precipitate with silver nitrate T.S., and does not with ammonium molybdate even when heated. The action of this salt upon the human economy is probably that of the phosphate. It has been highly recommended for removing some kinds of ink stains from colored cotton fabrics. It is said to remove the stains slowly without affecting the other colors.

Sodium Selenite. *Sodii Selenis.* Na_2SeO_3.—A white powder which freely dissolves in water. The aqueous 2 per cent. solution of *sodium selenite* stains bacteria red by the precipitation of *metallic selenium,* and has been highly recommended for the purpose of microscopic staining.

Sodium Silicate. *Sodii Silicas. Soluble Glass. Water Glass.—Sodium silicate* is made by fusing silica, fine sand, or powdered flint, powdered coal and dried sodium carbonate, mixed in powder, in an earthenware crucible, and pouring out the fused mass on a stone slab to cool. This is pulverized, and treated with boiling water, to dissolve the soluble part. The solution is filtered and concentrated. There are several forms known differing in the degree of hydration and the proportion of silica present. They are Na_2SiO_3-$NaSiO_3.9H_2O$ and $Na_2Si_4O_9$. The commercial solution of sodium silicate usually contains about 20 per cent. of silica and 10 per cent. of soda. In contact with acids the solution undergoes decomposition. It is employed in fixing fresco colors by the process of stereochromy, as a cement in the manufacture of artificial stone, and as an addition to soaps, constituting the so-called *silicate soaps.* It is also used in fireproofing fabrics and in waterproofing paper containers, etc. It is very popular as an egg preserving liquid. The eggs are carefully placed in a crock and covered over with sodium silicate solution of a certain strength. Sodium silicate has been employed as an antiseptic, in the treatment of chronic *urethritis, vaginitis,* etc., but R. Löwenhaupt asserts that when pure it is not antiseptic, any powers which it may seem to have being dependent upon the presence of free alkali in it. Sodium silicate has been suggested as a remedy in *pulmonary tuberculosis,* and Kuehn (*M. M. W.*, 1921, lxviii, p. 1612) believes that the lack of silicic acid is the cause of loss in elasticity of connective tissue, which is characteristic of advancing years, and has used intramuscular injections of sodium silicate with asserted benefit in the treatment of *arterial sclerosis.* He also claims good results in *bronchial asthma* and tuberculosis in the aged. He administered 2 cc. (30 minims) of a 1 per cent. solution intravenously at intervals of 3 or 4 days. Zeller (*M. M. W.*, 1912) recommends the internal use of a mixture of sodium and potassium silicate in the treatment of *external cancers* in conjunction with an arsenical paste. The mixture he employed contains three-quarters of a grain (0.048 Gm.) of each of the silicates, and he gave it three times a day.

Under the name of *Liquor Sodii Silicatis* the U. S. Pharm., 1890, formerly recognized the solution of sodium silicate, describing it as "a semi-transparent, almost colorless, or yellowish, or pale greenish-yellow, viscid liquid, odorless, having a sharp, saline, and alkaline taste, and an alkaline reaction. Specific gravity, 1.300 to 1.400 at 15° C. A drop of the solution, when held in a non-luminous flame, imparts to it an intensely yellow color. If a portion of the solution, largely diluted with water, be supersaturated with nitric acid, a gelatinous or pulverulent, white precipitate of silica hydrate will be produced." The solution is used in the preparation of mechanical dressings by the surgeon in the same class of conditions for which plaster of Paris is employed.

Sodium Silico-Fluoride. *Sodii Silico-fluoridum. Sodium fluosilicate.* Na_2SiF_6.—When gaseous SiF_4, generated by the action of sulphuric acid upon fluorspar in the presence of broken glass, is passed into water, hydrogen silico-fluoride, H_2SiF_6, is formed. This acid, when neutralized by sodium hydroxide or carbonate, will yield the sodium salt. It is a white odorless tasteless powder. It is difficultly soluble in water. A *solution of sodium silico-fluoride,* known as *salufer* has been asserted to be a powerful non-irritant antiseptic. The powder is a strong irritant or a mild caustic. The solution affects steel instruments. Bokenham, in experiments upon bacteria, found that in order to kill them it was necessary for the solution to be at least as strong as one to seven hundred and fifty parts, and that the drug has toxic properties, 0.05 Gm. of it causing prolonged nausea, great slowing of pulse, and reduction of arterial pressure.

Sodium Stearate. *Sodii Stearas.* $NaC_{18}H_{35}O_2$.—Sodium stearate of commerce contains varying proportions of sodium palmitate. It occurs as a white powder, with a fatty odor, soluble in hot water (with partial hydrolysis) or in hot alcohol. Pencils of sodium stearate, which have been recommended by T. G. Unna for use in *sycosis* and other parasitic skin diseases, are made as follows: Sodium stearate, 6 Gm.; glycerin, 2.5 Gm.; alcohol, sufficient to make 100 Gm. The affected part should be rubbed with the pencil five or six times daily.

Sodium Succinate. *Sodii Succinas.* $Na_2C_4H_4O_4 + 6H_2O$.—White crystals freely dissolving in water. Hammett (*J. A. M. A.*, 1917, lxix, p. 31) has found that the hypodermic injection of 1 cc. (grain one-sixtieth) of sodium succinate causes, in both normal and diseased persons, an increase of from 30 to 70 per cent. in the number of leukocytes in the blood which last for several days. *Sodium succinate* has been highly commended by Ch. F. Hope for *catarrhal jaundice. Dose,* fifteen to twenty grains (1.0–1.3 Gm.) every three or four hours.

Sodium Sulphocyanide. *Sodium Sulphocyanate. Sodium Rhodanide. Sodium Thiocyanate.* $NaCNS$.—Colorless deliquescent crystals or a white powder, very soluble in water. Bently and Le Roy have found that this salt has the power of rendering soluble the insoluble salts of calcium and magnesium and have suggested its use in the treatment of *arterial sclerosis* and *urinary calculus.* They administered it in *doses* up to one grain (0.065 Gm.). The remedy has also been suggested as a substitute for the iodides, especially in the treatment of chronic nervous conditions.

Sodium Sulphomethylate. *Sodii Methylsulphonas. Sodium Methylsulphonate.* $CH_2(OH)SO_3Na + H_2O$.—According to Rabuteau, this salt in 240-grain (15.5 Gm.) *doses* produces catharsis without cramp. (*A. J. P.*, 1880, 220.)

Sodium Sulphoricinoleate. *Sodium Sulphoricinate. Oleite.*—This substance may be prepared from castor oil by treating it with sulphuric acid at a low temperature, when a compound of sulphuric and ricinoleic acids is formed. This is known as *Turkey Red Oil* and is used in the textile and leather industries. The free sulphuric acid being removed by washing, and any unchanged oil by ether, the resulting *sulphoricinoleic acid* is then neutralized by sodium hydroxide, the finished product being a brown transparent, jelly-like liquid, with little odor, having an acrid taste, and soluble in water, alcohol, chloroform, and essential oils. It has remarkable solvent powers, dissolving phosphorus, iodine, phenol, resorcinol, naphthalene and many other medicinal substances. It was used as a glycerin substitute in Great Britain during the war. The phenol solution, often incorrectly called *phenol sulphoricinate,* is described below.

According to the experiments of Fred B. Kilmer (*Proc. A. Ph. A.*, 1890; *P. J.*, xx, 1890), its action upon mucous membranes, healthy and diseased skins, *cuts, burns,* etc., is highly soothing, and it may be taken internally or freely absorbed through the skin without danger. It would appear, therefore, to afford an excellent basis for ointments; but as productions made with it are very sticky, and often liable to harden, it is commonly best used by rubbing the substance with oleite, and then adding 50 per cent. of fatty base.

A mixture of sodium sulphoricinate and phenol is sold under the title *Phenolum Natro-sulphoricinicum* (*phenol sulphoricinate*). It is a yellowish, syrupy liquid, containing 25 per cent. of phenol and 75 per cent. of sodium sulphoricinate. The liquid itself mixes in all proportions with water, and has been especially commended as a local application in various *diseases of the skin* and in *tubercular* and other *ulcerations of the mucous membranes.* First, recommended by T. Heryng (*Th. M.*, 1896) as a local caustic application to *papilloma* and *ulcers* in the nasal and laryngeal passages, or diluted in various forms of chronic inflammation of the mucous membrane of the nose and larynx. These statements have been confirmed by various laryngologists. Prezedborski finds it of very great service both in *rhinitis atrophica* and *hypertrophica.* Berlioz (*B. G. T.*, 1890) especially recommends it in *diphtheria.* The 20 per cent. aqueous solution is to be applied locally to the throat four times a day and once or twice in the night. (*S. M.*, 1892.)

Sodium Sulphovinate. *Sodium Ethylsulphate.* $C_2H_4(OH)SO_3Na + H_2O$.—This salt occurs as a white, granular powder or in hexagonal tabular crystals, according to the method of its preparation. Its taste is cooling and rather aromatic, nearly destitute of bitterness. It is very deliquescent, and is soluble in 0.7 part of water.

It is made by the interaction of alcohol and sulphuric acid under carefully controlled conditions. For methods of preparation see *U. S. D.*, 19th ed., p. 1653.

Sodium sulphovinate is said to be a mild although active cathartic. According to Rabuteau, five drachms (19.4 Gm.) of it dissolved in three glasses of water will generally produce in the adult four or five liquid stools without pain. The *dose* for children is from two to three drachms (7.7–11.6 Gm.). The pleasantness of its taste and action would render it a favorite purgative were it not for its high price and the difficulty of preserving it, all of the sulphovinates having a great tendency on exposure to the air to break up into alcohol and a salt of surphuric acid.

Sodium Tartrate. *Sodii Tartras.* $Na_2C_4H_4O_6.2H_2O = 230.06$.—Sodium tartrate was suggested some years ago as an agreeable purgative having the advantage over other saline laxatives of being almost without taste. It occurs in the form of white crystals freely soluble in water. The dose employed was from four to eight drachms (15 to 30 Gm.).

A *solution of sodium tartrate* made by mixing solutions of tartaric acid and sodium bicarbonate and flavoring with lemon syrup has been used as a substitute for solution of magnesium citrate. For formula see *U. S. D.*, 20th ed., p. 1617.

Sodium Thiophene Sulphonate. $NaC_4H_3S_2O_3 + H_2O$.—A white powder containing about 33 per cent. of sulphur. It is soluble in water and is used either in a 5 to 10 per cent. solution or ointment in the treatment of *skin diseases.*

Sodium Valerate. *Sodii Valerianas. Sodii Valeras.* C_4H_9COONa.—This salt was dismissed from the U. S. Pharmacopœia in 1870, and from the British Pharmacopœia in 1898. For a process for preparing it, see *U. S. D.*, 19th ed., p. 1654. *Sodium valerate* is a deliquescent, very soluble salt, in snow-white masses, having the disagreeable odor of valeric acid, and a taste at first styptic but afterwards sweetish. When heated to 140.5° C., it fuses without loss of acid, and upon cooling concretes into a white solid. It is little used medicinally, having been originally introduced into the Dublin Pharmacopœia in 1850 for the sole purpose of forming, by double decomposition, iron, quinine, and zinc valerates. *Dose,* as a nervous stimulant, one to five grains (0.065–0.32 Gm.).

Soja. *Glycine Soja* Sieb. and Zucc. (*Glycine hispida* Maxim.) (*Soja hispida* Moench.) *Soy Bean. Soja* or *Sahuca Bean. Miso. Coffee Bean.* (Fam. *Leguminosæ.*)—*Soja* is an important food plant and forage crop. It is an annual having hairy, trifoliate leaves, inconspicuous, white or purple flowers, and axillary clusters of small, pendulous, hairy legumes containing 2 to 5 seeds. The latter are yellow, green, brown, black or parti-colored. Stingl and Morawski (*Monatsschrift für Chemie,* April, 1886) have determined the presence in this bean of a ferment said to be one of the most powerful known in its action upon starch, two-thirds of which it converts into sugar and one-third into dextrin. Soy beans are an important article of diet in China and Japan, three important products are made from them—namely, soy bean milk, soy bean cheese and soy bean sauce called *shoju* or *shoyu.* In this country they have been used as a coffee substitute. Soja bean has been suggested as a diabetic food, but it contains upwards of 25 per cent. of carbohydrates. Sinclair has highly recommended the soy bean as an infant food in *summer diarrhea* and similar complaints. (*J. A. M. A.*, 1916, lxvi, 841.)

The average composition of soy beans is water 10 per cent., fat 18 per cent., protein 40 per cent., carbohydrates 22 per cent., crude fiber 5 per cent., ash 5 per cent.

The proteids are remarkable for the large proportion soluble in water (over 75 per cent.). The carbohydrates are about equally divided between sucrose and starch with some dextrins and other carbohydrates. No reducing sugar is present. The seeds also contain *urease*, an enzyme which decomposes urea with the formation of ammonium carbonate, and is used for the determination of urea in the urine or other fluids.

Solanine.—A physiologically active substance obtained from the sprouts of *Solanum tuberosum* L. (potato), and other *Solanaceæ.* It is classed both as a glucoside (because of its being decomposable into glucose), and also as an alkaloid (because of its basic properties). *Solanine* is in the form of a white, opaque powder, or of delicate acicular crystals, somewhat like those of quinine sulphate, though finer and shorter. It is inodorous, of a bitter taste. The divergence of formulas which have been given by chemists for solanine suggests very strongly that either the substances investigated were in an impure state or that there are several allied compounds found in this group of plants. Firbas (*Monats. f. Chem.*, 1889, x, 541) reports two alkaloidal glucosides in the potato, *solanine* and *solaneine.* Subsequently Davis (*P. J.*, 1902, xv, 160) reported the same two principles in the dulcamara. The melting point of solanine is variously given from 235° C. (Davis) to 250° C. It is not affected by alkalies but when boiled with dilute acids is hydrolized into a mixture of sugars and *solanidin.* Solanine is practically insoluble in water or ether or chloroform, sparingly soluble in hot ethyl alcohol, but easily in amyl alcohol. It is scarcely alkaline to litmus but is capable of neutralizing acids. It is distinguished by the deep brown or brownish-yellow color which iodine imparts to its solution, and by its reaction with sulphuric acid, which becomes first reddish-yellow, then purplish-violet, then brown, and, lastly, again colorless, with the deposition of a brown powder. This test is said not to be interfered with by the presence of morphine. The salts which solanine forms with acids are mostly amorphous in character. The oxalate, chromate, and phosphate form crystalline crusts. The acid sulphate is said to be very stable, and is not decomposed by water even on heating, in contradistinction to the neutral salt. It is amorphous and very bitter.

The physiological action of solanine is very similar to that of the saponins. Perles (*A. E. P. P.*, 1889, xxvi) found that when mixed with the blood outside of the body it caused rapid coagulation with destruction of the blood corpuscles. In the frog it produced a centric paralysis, with later paralysis of the heart. In mammals it produced excitement, with tremors, followed by central paralysis, collapse, and death in deep coma, preceded by a fall of temperature which is so great as to be almost characteristic. Vomiting and diarrhea were frequently observed, and the urine contained albumin and often hemoglobin. After death inflammation of the gastro-intestinal mucous membranes, and also a parenchymatous and even hemorrhagic nephritis were found. According to Capparoni (*B. G. T.*, May, 1888), minute doses of solanine, while diminishing the rapidity of the heart's action, increase at the same time the arterial pressure.

In the researches of Max Perles, the action of *solanidine* was very similar to that of solanine, the chief difference between the two being that solanine is a violent local irritant, while solanidine seems free from local irritant properties.

Solanine has been used with asserted benefit by Capparoni (*B. G. T.*, May, 1888) and others, as an antispasmodic remedy in *asthma, bronchitis* and *cystitis.* It is also attributed with a sedative action on the central nervous system, and has been used by Capparoni in the treatment of ataxic pains. Waugh (*J. A. M. A.*, 1906) asserts that it is of great service in *epilepsy.*

Schmiedeberg (*A. E. P. P.*, 1899, xxxvi, 361) describes an epidemic of solanine poisoning from sprouted potatoes in which the symptoms were headache, colic, vomiting, diarrhea, dilated pupils, first accelerated, then slowing of the pulse, mental confusion and sometimes unconsciousness. Hansen (*Science*, 1925, lxi, 340) has reported a similar group of poisonings occurring in an Illinois family, two of whom died.

The *dose* of solanine, as given by different writers, varies widely, probably because of varying degrees of purity of the drug employed.

Waugh states that of the pure alkaloid, the proper *dose* is one-twelfth of a grain (0.005 Gm.), but other writers have given much larger amounts.

Solanum.—The genus *Solanum* (Fam. *Solanaceæ*) contains a number of species which are possessed of active physiological properties and some of which have been used to a considerable extent in medicine. The *S. Carolinense* and *S. Dulcamara* are recognized by the N. F. under the titles of *Solanum* and *Dulcamara* respectively, and are described in Part I.

S. aculeatissimum Jacq., known as *Apple of Sodom*, is indigenous to Brazil. It is a spiny undershrub with pinnately 5–7 lobed leaves, white flowers and orange-colored berry-fruits, the latter containing *solanine.*

S. bacciferum (?), of Jamaica, yields the so-called *Susumber berries*, which are habitually used as fruit by the natives, but Manners has recorded in the *Ed. M. J.*, 1867, fatal poisoning by these berries, death being preceded by dilated pupils and collapse. It is probable, however, that the berries were not true susumber berries but were the product of some other species of solanum.

S. Chenopodium F. Muell.—In this plant, which is a native of Queensland, C. E. Sage has found the alkaloid *solanine.* According to E. B. Ormerod the plant is useful in the treatment of *dysentery.* (*P. J.*, lxviii, 1902.)

D. Freire has obtained from the fruit of *S. grandiflorum* Hort., or *wolf fruit*, a twining shrub of Brazil, a toxic alkaloid, *grandiflorine.* (*C. R. A. S.*, cv.)

S. Jacquinii Willd. is used in India as a diaphoretic and expectorant.

S. Lycopersicum L. *Tomato Plant* (formerly termed the *Love Apple*).—The tomato is believed by many practitioners to be an injurious article of diet to gouty persons. The acidity of the juice is due at least in part to citric, malic and oxalic acids. Solanine is said not to be present in the juice but has been found by George W. Kennedy

(*P. J.*, 1873) in the herbaceous part of the plant. It probably also exists in the seeds. (*A. J. P.*, xxxiv.) Tomato is exceptionally rich in vitamines.

S. nigrum L. *Black*, or *Garden*, or *Common Nightshade. Duscle. Hound's Berry. Morelle.*—This is an annual herb in temperate climes although an undershrub in tropical regions. Its leaves are simple, ovate, entire or sinuate-dentate. Its flowers are small and white and its fruits, which are sparingly employed for pies and jams, are globular berries about ¼ inch in diameter. Its occurs widely in shaded and rich open ground throughout the United States. The leaves and tops of this plant have been recently admixed with and substituted for *Belladonnæ Folia.* They may be readily detected by their absence of glandular hairs, by the rotate corolla and by the smaller size of the leaves which are frequently wavy-toothed. The leaves have been used in medicine in the treatment of *scrofulous dyscrasias*, and are said to produce diaphoresis when in overdose; also nausea, purging, and nervous disturbance. The poisonous properties commonly attributed to this plant are, however, to be doubted, since Dunal of Montpellier, states, as the result of numerous experiments, that the berries are not poisonous to man or the inferior animals; and the leaves are said to be consumed in large quantities in the Isles of France and Bourbon and in the Hawaiian Islands by the natives as food, having been previously boiled in water. In the latter case the active principle of the plant may have been extracted by decoction. Introduced by importers under the name of *jurubeba*, this plant was examined by Kobert and found to be inert. According to Peckoldt, however (*Ph. Rund.*, 1889), true jurubeba is *Solanum insidiosum* Mart., from which the results would have been more favorable. It is used in Brazil in *gonorrhea* and *syphilis*.

S. Pseudocapsicum L., *Jerusalem*, or *Winter, Cherry.*—This is a small branching shrub of the tropics and sub-tropics and widely cultivated for greenhouse or house decoration when covered with its bright colored berries. It yields a fruit whose resemblance to the common cherry is said to have led to its being eaten by children with fatal results.

S. rostratum Dunal. *Sand Bur. Buffalo Bur. Beaked Nightshade. Bull Nettle.*—This very prickly plant, which grows on the prairies from Nebraska to Mexico, and is noteworthy as having been the original food of the Colorado bettle or potato bug, has yielded to W. S. Amos an alkaloid. (*Notes on N. R.*, iv.)

S. tuberosum L. *Potato.*—The *common white potato* is a perennial, weak-stemmed herb indigenous to low valleys of Chile, Peru and Bolivia and widely cultivated throughout the world on account of the popularity of its tubers as a food. The herbage appears, at certain stages of growth, to be toxic and several cases of poisoning have been reported from potato sprouts (see under *Solanine*).

Solidago. *Golden-rod. Verge d'Or*, Fr. *Goldruthe*, G. (Fam. *Compositæ.*)—This is a large genus of perennial herbs most of the species of which are native to the Eastern half of North America. Of these *S. odora* Ait., or the *Sweet Golden-rod*, was formerly official. *S. Virgaurea* L. [*S. Randii* (Porter) Britton], or *European Golden-rod* occurs on dry or granitic soil in the northern United States and Europe, and was formerly directed by the Dublin College. It is aromatic, astringent, in hot infusion diaphoretic, and is asserted to be diuretic. (*Rev. Gén. de Clin. et de Thérap.*, 1889.) For an analysis of *S. rugosa* Mill., see *A. J. P.*, 1893, 122.

Species of golden-rod are of medical importance as causative agents of hay-fever (see under *Diagnostic Tests*).

Soluble Mercury of Hahnemann. $NH_2(Hg_2)NO_3$.—This is prepared by adding, drop by drop, a diluted solution of ammonia to an equally diluted solution of mercurous nitrate, until the precipitate begins to be paler than at first. It is a black powder. When it has a gray color, the fact shows that too much ammonia has been employed in its precipitation. In this case $NH_2(Hg_2)NO_3$ yields $NH_2(Hg)NO_3 + Hg$. This preparation was at one time included in the French Codex. It has been used in *syphilitic* diseases.

Solurol. *Hyminic Acid. Nucleotinphosphoric Acid.* $C_{30}H_{46}N_4O_{15}.2P_2O_5$.—A yellow amorphous powder, easily soluble in water. It is used as an uric acid solvent in *gout, rheumatism* and similar affections. *Dose*, four to eight grains (0.25–0.5 Gm.).

Solution of Dialyzed Iron. *Liquor Ferri Dialysatus. Liquor Ferri Oxychlorati*, P. G.—*Dialyzed solution of iron* was formerly recognized by the Br. Ph. It is made by treating a solution of ferric chloride with ammonia, whereby ferric hydroxide is precipitated, which by agitation is dissolved, placing the thick liquid in a dialyzer, and suspendng this in water, which is to be constantly renewed so long as any traces of hydrochloric acid are found in it. The following process has been used in the United States: To one hundred parts of solution of ferric chloride, sp. gr. 1.26, thirty-five parts of ammonia water, sp. gr. 0.923, may be gradually added. The precipitate which almost immediately forms is redissolved, and the solution introduced into the dialyzer, which is then suspended upon the water, contained in a suitable vessel. When the water in the outer vessel ceases to produce a precipitate with silver nitrate, or to show an acid reaction, the preparation in the inner vessel is assayed by evaporating 10 cc. to dryness on a water bath, to ascertain the amount of ferric oxychloride in solution; then the final solution is diluted so that it shall contain 10 per cent. of dry oxychloride.

Dialyzed iron is a colloidal solution of *ferric oxychloride* in water. The solution is of a transparent reddish-brown color, free from the usual astringent, styptic taste of iron preparations. It mixes in all proportions with distilled water, alcohol, syrup, and glycerin, but water containing any saline impurity is apt to cause precipitation. When gelatinization occurs, agitation with a small quantity of solution of ferric chloride will usually restore it to fluidity, care being observed not to add in excess. Contact with the alkalies should be avoided, even in minute quantity, indeed it is best administered without addition of any kind, or simply diluted with distilled water.

The British Pharmacopœia formerly directed that its specific gravity should be 1.047, and "100 grains should afford a precipitate with a solution of ammonia which, washed, dried and ignited, weighs five grains." E. B. Shuttleworth (*Can. Pharm. Journ.*, Dec., 1877) recommends a solution which has the sp. gr. 1.040 and yielding 5 per cent. of residue when well dried on a water bath as the best for medicinal use. The specific gravity test can be relied upon, if the solution does not give a precipitate with silver nitrate or become of a blackish-blue color upon treatment with tannin, showing the absence of free ferric chloride. There is good reason for believing that much of the so-called dialyzed iron formerly found in commerce was made by adding freshly precipitated ferric hydroxide to solution of ferric chloride until it ceased to be dissolved and then filtering the solution. *Ferrum catalyticum*, or *catalytic iron*, used in Europe, is probably made in this way.

Dialyzed iron is also upon the market in the form of scales which enable the solution to be prepared extemporaneously.

Solution of dialyzed iron has been very highly praised as a ferruginous tonic free from astringency. It is capable of acting as an antidote to arsenic by virtue of the readiness with which it yields hydrated ferric oxide, but it is safer to depend upon the official antidote, ferric hydroxide with magnesium oxide (see *Ferri Hydroxidum Cum Magnesii Oxido*). *Dose*, from one-half to one fluidrachm (1.3–3.75 cc.).

Solution of Magnesium Bisulphite. *Liquor Magnesii Bisulphitis.*—George Archibald, having found that magnesium bisulphite is capable of arresting the butyric acid fermentation, proposed a solution of it as a remedy in *heartburn*. He prepared it by treating the magnesium carbonate with sulphurous acid, adding to an ounce of water sixteen grains of the sulphite thus formed, and passing sulphurous acid gas through the mixture until a clear solution is obtained. (*P. J.*, 3d series, ii, 502.)

Solvents for Industrial Purposes.—A surprisingly large number of solvents have made their appearance since the stimulus of chemical research produced during the World War. Liquid organic chemical compounds which had hitherto been purely academic or research interest were produced on a large size manufacturing scale, as for instance ethyl acetate which is now available in tank car lots. Particularly along the lines of research in lacquers, cellulose-derivative varnishes, etc., has the competition been particularly keen to find the solvent with the ideal properties. These ideal qualities are not easy to describe briefly, but among the foremost qualities desired are, freedom from color, freedom from objectionable odor, immiscibility with water, freedom from hygroscopic qualities.

A recent article in the *J. I. E. C.*, 1925, p. 560 enumerates the following solvents in the accompanying classifications; those not italicized are described elsewhere in this volume.

Solvents boiling below 100° C.: Ethyl Acetate (77°); *Methyl Acetate*, CH_3COOCH_3 (56°–57°); *Ethyl Propionyl*, CHCOCH (98°–102°); Ethyl Alcohol (78°); Isopropyl Alcohol (82°); Acetone (57°); Benzene (80°).

Solvents boiling about 125° C.: *Diethyl Carbonate*, $C_2H_5CO_3C_2H_5$ (125°); *Butyl Acetate*, $CH_3COOC_4H_9$ (125°); Amyl Acetate (138°–142°); Ethyl Butyrate (121°); *Butyl Alcohol*, C_4H_9OH (117°); Amyl Alcohol (126°–132°); Toluene (111°).

Solvents boiling between 150° and 200° C.: *Ethyl Lactate*, $CH_3CHOHCOOC_2H_5$ (155°); *Ethyl Acetoacetate*, $CH_3COCH_2COOC_2H_5$ (181°); *Diethyloxalate*, $(CO_2)_2(C_2H_5)_2$ (186°); *Ethyl Benzoate*, $C_6H_5COOC_2H_5$ (212°); Benzyl Alcohol (205°); *Diacetone Alcohol*, $(CH_3)_2COH.CH_2COCH_3$ (164°); Xylene (143°).

Solvents boiling near 300° C., or above: *Tricresyl Phosphate*, $(C_7H_8)_3PO_4$ (below 350°); *Triphenyl Phosphate*, $(C_6H_5)_3PO_4$ (below 325°); *Diethylphthalate* (290°); *Dibutylphthalate*, $C_6H_4(COOC_2H_5)_2$ (below 340°); *Diamylphthalate*, $C_6H_4(COOC_5H_{11})_2$ (340°); *Diethyl Tartrate*, $C_4H_4O_6(C_2H_5)_2$ (below 280°); *Triacetin*, $(C_2H_3O_2)_3C_3H_5$ (267°).

The evaporation time of these solvents is a matter of great practical importance. Some solvents evaporate completely within a reasonably practical time. Ethyl acetate is the speediest in this respect and anhydrous ethyl alcohol next. These facts are of great economic importance in the manufacture of automobile lacquers particularly.

Elasticity of the film in lacquers is produced by the agency of what are known as *plasticizers.* Among the more important plasticizers are: diethylphthalate, diamylphthalate, dibutylphthalate, triphenylphthalate, phosphate, tricresyl phosphate, butyl tartrate, and camphor.

Somatose.—This is an artificially digested meat albumin containing 51.6 per cent. of deutero- and 13.4 per cent. of hetero-albuminoses, 5 per cent. of peptone, 1 per cent. of moisture, and 5 per cent. of nutrient salts. A yellowish, odorless, and almost tasteless powder.

Iron Somatose is a similar preparation containing 2 per cent. of iron in combination.

Milk Somatose is a soluble nutrient prepared by the same digestive process from casein, containing 5 per cent. of tannin. It is a light yellowish powder, readily soluble in water.

Somnoform.—A proprietary anesthetic said to contain ethyl chloride 60 per cent., methyl chloride 35 per cent., ethyl bromide 5 per cent. It was at one time widely used as a general anesthetic specially for dental operations. While it has been stated that it possesses no unpleasant aftereffects when properly administered, the numerous cases where stomachic disturbances have arisen after its use would lead one to doubt this statement. (For a study of its physiological action, see *B. M. J.*, 1903, 1.)

Sonchus. *Sonchus oleraceus* L. *Sow Thistle.* (Fam. *Compositæ.*)—A coarse weed, having runcinate-pinnatifid leaves clasping by a heart-shaped base and producing corymbs of pale yellow flowers in summer and autumn. This European plant is commonly found in waste places around dwellings in the United States. The brownish gum left after the evaporation of the juice of this plant is said to be a powerful hydragogue cathartic, in *doses* of from two to four grains (0.13–0.26 Gm.). Combined with aromatics or belladonna, it may be used instead of elaterium in *dropsy.* (*Med. Bull.*, July, 1888.) It has also been used as a so-called cure for the opium habit. (*Pac. Pharm.*, 1908, 113.)

Soot. *Fuligo Ligni.*—This well-known substance has a peculiar odor, and a bitter, empyreumatic, and disagreeable taste. Its composition varies according to the source and conditions of its formation. When obtained by the combustion of resinous materials it may contain oily distillation products soluble in ether; when obtained by the combustion of wood it may contain pyroligneous (acetic) acid and products peculiar to wood tar, such as creosote, guaiacol, and phenols. Of course mineral substances from the ash of the wood may also be present.

Soot was formerly official with the Edinburgh College, and the Scotch physicians prescribed it as a tonic and antispasmodic. It has also been employed as an external remedy in skin diseases. (See 14th ed., *U. S. D.*)

Sophora. *S. speciosa* Benth. *Coral Bean* (Fam. *Leguminosæ*).—From the poisonous seeds of this Texan tree, H. C. Wood obtained a volatile liquid alkaloid *sophorine*, which, according to P. C. Plugge, is identical with cytisine, $C_{11}H_{14}ON_2$. This same alkaloid probably exists in many species of the genus, as Parsons found a liquid alkaloid in *S. sericea* Nutt., *crazy-weed*, which grows in the prairies of Nebraska and Kansas to Colorado, Texas and Arizona. (*Rep. Commissioner of Agricult.*, 1879, and *N. R.*, 1881, 67.) Greshoff (*P. J.*, xxii) found a poisonous alkaloid in the leaves of *S. tomentosa* L., the seeds and roots of which are used in Ceylon and Java as a remedy for *cholera*. Plugge, however (*A. Pharm.*, 1895) affirms that *matrine*, the alkaloid discovered by Nagai in *S. angustifolia*, is distinct from cytisine. Kondo (*J. Pharm. Soc. Japan*, 1921, p. 1047) finds that is a monoacidic tertiary amine and assigns it the formula $C_{15}H_{24}N_2.CO$.

Sorbus. *Sorbus Aucuparia* L. (Now *Pyrus Aucuparia* (L.) Erhr.) *Mountain Ash. Rowan Tree. Sorbes*, Fr. *Eberesche, Vogelbeere*, G. (Fam. *Rosaceæ.*)—A European tree with odd pinnate leaves having numerous leaflets, compound corymbs of white flowers and small, bright red, pome-fruits. It is extensively cultivated in the United States and becoming naturalized. Its fruit contains a peculiar kind of sugar called *sorbinose*, $C_6H_{12}O_6$, isomeric with levulose. It reduces Fehling's solution, but is not fermentable with yeast. Hoffmann has also discovered two new acids, which he designates as *sorbic* and *parasorbic acids*, $C_6H_8O_2$. Sorbic acid forms colorless needle-like crystals fusing at 134.5° C., while parasorbic acid is a lactone-like body, which, on heating with concentrated acids or solid alkali, changes into sorbic acid. M. J. Boussingault has found in it a crystalline saccharine principle, *sorbitol*, isomeric with mannitol, melting, when anhydrous, at from 110° to 111° C., when hydrated, at 102° C. Its formula is $C_6H_{14}O_6$. It does not undergo the vinous fermentation. (*P. J.*, 1872, 28.) The seeds of the fruit contain 22 per cent. of fixed oil. The fruit has been used in *scurvy*, and in infusion, as a remedy in *hemorrhoids* and *strangury*. All parts of the tree are astringent, and may be employed in tanning and dyeing black. *S. americana* Marsh. (now *Pyrus americana* (Marsh.) DC.), or *American Mountain Ash*, probably has similar virtues to the European species. Edwin Johanson found the fruit to yield from 4.92 to 6.6 per cent. of malic acid. (*Ph. Z. R.*, i, 1882.)

Sorghum.—This is a group of annual fodder-grasses whose outstanding characteristic is their inflorescence which is an open or contracted panicle of spikelets arranged in threes. There are a number of varieties and these are usually distinguished as "saccharine" sorghums and "non-saccharine" sorghums. The former are tall, leafy, contain a sugary sap and are referred to *Andropogon Sorghum* var. *saccharatus* Koern. The latter include the *kafirs, milos, durra* and *broom corn*, all of which are varieties of *Andropogon Sorghum* (L.) Brot. All of our sorghums are believed to have been derived from a wild progenitor, the *Andropogon halepensis* (L.) Pers. or *Johnson Grass*. The saccharine sorghums are cultivated in the United States to some extent as a forage crop. They are not used in the manufacture of sugar, owing to the difficulty of effecting its crystallization. Broom corn has been cultivated in the United States since 1798 and is especially adapted to the manufacturer of brooms and brushes. In some of the semi-arid districts of the West it is reported that cattle have been poisoned from eating of the green sorghum, usually of a second growth. This is apparently due to the production of hydrocyanic acid in the leaves.

The non-saccharine sorghums, *Kaffir corn* and *Durrha*, were used during the war as officially permitted substitutes for wheat.

Sozoiodolic Acid. *Sozoiodol. Diiodoparaphenolsulphonic Acid, Crystalline.* $C_6H_2I_2(SO_3H)OH + 1\frac{1}{2}H_2O$.—This is a white glistening powder, odorless, of slightly acid taste, slightly soluble in cold water, more easily in hot water. It is decomposed on heating to 200° C., giving off violet vapors. It contains about 53 per cent. of iodine. It can be recognized by heating, or by adding sulphuric acid to it in hot solution, when iodine separates. Ferric chloride imparts a dark violet color to the aqueous solution; silver nitrate throws down a white precipitate of silver soziodol completely soluble in diluted nitric or sulphuric acid. For an outline of the process of manufacture, see *Squibb's Ephem.*, Feb., 1893. Soziodol is used as a local remedy, resembling somewhat iodoform in its range of usefulness. According to Langaard, 2 per cent. is sufficient to kill bacteria of pus; for wounds, a 10 per cent. mixture with powdered talc is advocated. Lassar praises it in *eczema*, *herpes tonsurans, impetigo*, etc.; it has also been much used in *otitis* and *rhinitis*. Langaard has found that fifteen-grain doses have no appreciable effect upon rabbits, and Bufalini gave twenty-two grains a day in *phthisis* without unpleasant effect. The soziodolates have also been called by the proprietary name of *Ronozol salts*. The following salts have been used:

Potassium sozoiodol, sparingly soluble; a desiccant indicated in *eczema*. It is usually employed with talc in the proportion of 1:5 or 1:6. *Zinc sozoiodol*, a local irritant in solutions of from 1:20 to 1:50; a caustic, in a solution of 1:5. *Mercury sozoiodol*, a caustic, even in a solution of 1:10. Miller affirms that its solution of 2½ per cent. kills the acarus of *scabies* in twenty-four minutes. It has been used as an antisyphilitic in *doses* of one grain (0.065 Gm.).

Schwarz recommends pills, each containing one-third of a grain of sozoiodol mercury and one-fifteenth of a grain of powdered opium. (*Th. M.*, 1908, 299.)

Sodium Sozoiodolate (*sodium soziodol*) occurs as colorless, inodorous, crystalline needles, soluble in about fifteen parts of water, also soluble in alcohol or glycerin. The finely powdered substance mixed with equal parts of sulphur is employed by insufflation in treating *diphtheria, laryngitis, nasal tuberculosis*, etc. It is also used in a 2 to 5 per cent. solution as an antiseptic douche or wash in *gonorrhea*.

Sozolic Acid. *Acidum Sozolicum. Phenolsulphonic Acid. Aseptol.* $C_6H_4(SO_3H)OH$.—Ortho and paraphenolsulphonic acids are both formed when phenol is dissolved in concentrated sulphuric acid; at medium temperatures the former is far more abundant, but it readily passes into the para compound on the application of heat. Sozolic acid has a very faint odor of phenol. The paraphenolsulphonic acid alone is the basis of the formerly official phenolsulphonate. It is readily soluble in water, alcohol, and glycerin, and is used so diluted as to contain from 3 to 10 per cent. of the active principle. The orthophenolsulphonic acid in 33⅓ per cent. solution has received the trade name of *aseptol*. The ortho acid changes on heating into the isomeric paraphenolsulphonic acid, and this change takes place even in the aqueous solution of the former, a fact which should be remembered in the preparation of aseptol solutions.

E. Riegler (*W. M. Bl.*, xviii, 1895) proposes aseptol as a test for albumin in urine. One part in 20,000 causes coagulation; the precipitate with albumin does not disappear with heat. The solutions of albuminose and peptones are also precipitated, but the precipitates of these disappear with heat. The solution of aseptol undergoes decomposition when exposed to light.

Schiff and Beilstein asserted that phenolsulphonic acid acts like tannic and gallic acids, precipitating albumen and alkaloids, and being capable of replacing gallic acid in the making of leather and in pharmacy. There is, however, no sufficient reason for believing that the substance can be used in medicine in the place of the vegetable acids named. It has also been asserted that phenolsulphonic acid is a powerful antiseptic, but in a careful series of comparative experiments, F. A. Tucker (*Notes on New Remedies*, 1892) found that it had not more than one-third the antiseptic power of phenol.

Sparteine Sulphate. *Sparteinæ Sulphas. U. S. IX.*—The alkaloid sparteine is described in Part I under *Scoparius* from which drug it is obtained. The U. S. IX recognized the sulphate and officially described it as in "colorless, rhombohedral crystals, or as a crystalline powder; odorless, and having a slightly saline and somewhat bitter taste. It is hygroscopic. One Gm. of Sparteine Sulphate dissolves in 1.1 mils of water and in 3 mils of alcohol at 25° C.; insoluble in chloroform or ether. Its aqueous solution (1 in 20) is neutral or acid to litmus. Add 25 mils of ether and a few drops of diluted ammonia water, avoiding an excess, to about 0.1 Gm. of Sparteine Sulphate in a test tube, then add to the mixture an ethereal solution of iodine (1 in 50) until the liquid, when shaken, turns from an orange to a dark reddish-brown color. After a short time, the bottom and sides of the test tube will be coated with minute, dark greenish-brown crystals. Barium chloride T.S. produces a white precipitate insoluble in hydrochloric acid when added to an aqueous solution of Sparteine Sulphate. Incinerate about 1 Gm. of Sparteine Sulphate; not more than 0.1 per cent. of ash remains. A solution of about 0.1 Gm. of the salt in 2 mils of sulphuric acid is colorless (*readily carbonizable organic impurities*). Shake about 0.1 Gm. of Sparteine Sulphate in a test tube with 5 mils of potassium hydroxide T.S., the liquid at first becomes turbid, and small, colorless or nearly colorless drops of sparteine gradually collect on the surface. Suspend a strip of moistened red litmus paper in the mouth of a test tube, and apply a gentle heat; the test paper gradually acquires a blue color, but no odor of ammonia is perceptible (*ammonium salts*). A mixture of about 0.1 Gm. of Sparteine Sulphate, 0.5 mil of chloroform and 0.5 mil of alcoholic half-normal potassium hydroxide V.S. does not emit an odor of phenylisocyanide on heating (*aniline*)." *U. S. IX.*

G. Marque (*J. P. C.*, xxx, 555) states that if a small quantity of sparteine sulphate be mixed with about one-third of its weight of chromium trioxide, and gently heated in a porcelain dish, the mass will soon turn green and emit a strong odor resembling coniine. Moureu and Villier (*Bull. Soc. Chim.*, 1903 (6), 12, 545) confirm Stenhouse's formula for sparteine sulphate, $C_{15}N_{26}N_2.H_2SO_4 + 5H_2O$.

The statements of different investigators both clinical and pharmacological, concerning the effects of sparteine have been so extraordinarily contradictory that they are at present impossible of reconciliation; one is perforce driven to the belief that the different investigators did not have the same principle. It has been variously claimed to accelerate and to slow the pulse rate, to increase and to diminish the contractile power of the heart, to arrest the heart in systole and in diastole, to raise the blood pressure or to lower it, and finally to have no effect on the circulation whatsoever. Again it is claimed by some that it diminishes, and by some that it increases the quantity of urine, and by others that it has no effect upon the kidney. These discrepancies cannot be harmonized on the ground of difference in dosage. For review of the extensive literature upon the subject, the reader is referred to McNider (*Southern Med. Journ.*, 1910, iii, p. 498), and to Pilcher and Sollmann (*J. P. Ex. T.*, 1915, vi, p. 373). It has been used clinically in the treatment of various forms of cardiac disorders, such as *endocarditis*, but especially in such functional derangements as *nervous palpitation*, the *tachycardia of Grave's disease*, etc. It has also been employed as a diuretic in *dropsies*, especially when due to cardiac lesions. The doses recommended by various authors have ranged from one-sixth of a grain to as high as two grains (0.010–0.13 Gm.).

See also *Oxysparteine*.

Spartium. *Spartium junceum* L. *Spanish Broom.* (Fam. *Leguminosæ.*)—A small shrub, indigenous in the south of Europe, and cultivated in our gardens as an ornamental plant. The flowers are large, yellow, and of an agreeable odor. Spanish broom, in its medicinal properties closely resembles *Scoparius*, but appears to be from five to six times more active, 6 Gm. of the dried plant, given in infusion, having produced very violent poisoning; serious results have been produced by the substitution of the Spanish for the true broom. The dried flowers are readily differentiated, those of the *true broom* having a small, bell-shaped calyx with two unequal lobes, the upper of which is bidentate, the lower minutely tridentate, and the style always rolled, while in *Spartium junceum* the calyx is deeply cleft to the base on one side only, and the style is deeply rolled.

The symptoms produced by overdoses are vomiting and purging, with renal irritation. The seeds have been used to a considerable extent in *dropsy* in *doses* of from ten to fifteen grains (0.65–1.0 Gm.) three times a day in the form of tincture.

Sphæranthus. *Sphæranthus indicus* L. (Fam. *Compositæ.*)—An herbaceous plant having winged stems and widely distributed in Africa, Asia and Australia. It is used as a general tonic, deobstruent, alterative, and aphrodisiac, under the names of *Mundi Gorakhmundi*, *Murmuria*, and *Kottakkarandai*. Dymock has found it in a deep cherry-colored essential oil.

Sphagnum. *Peat Moss. Bog Moss.*—The sphagnums (Fam. *Sphagnaceæ*) comprise a group of pale mosses found in swamps and bogs throughout the entire North Temperate Zone. Great masses of these plants accumulate in the areas they inhabit on account of their prolific manner of growth and slow decay. The lower growth is constantly dying away and forming peat, whence the name of *peat moss* assigned to them. They differ from the true *mosses* (*Bryales*) in being paler green in color, in forming taller growths, in possessing no absorptive hairs in their sporophyte generation, as well as in the structure of their reproductive parts. Their stems and leaves possess colorless cells, connected by small perforations, that have the capacity of sucking up and retaining large quantities of liquid.

During the Great European War dried peat moss was largely employed for its absorptive powers as a surgical dressing. The species chiefly employed were the *Sphagnum imbricatum*, *S. palustre*, *S. Magellanicum*, and *S. papillosum*. The moss, after being collected, was spread out and partially dried in the sun and then completely dried by artificial heat and often afterwards treated with some disinfectant as corrosive sublimate. It has been asserted that sphagnum makes a more absorbent dressing than the ordinary absorbent cotton.

Spider Poisons.—The popular belief that certain spiders have the power of poisoning small animals, and even man, has received confirmation, and an active principle, *arachnolysin*, has been separated by Sachs and found to have a powerful hemolytic action upon the blood of rabbits and cats but not to affect dogs and guinea-pigs.

There has been a long standing tradition that the *tarantula* bite was fatal but Baerg (*J. Parasitol*, 1921, viii, p. 86) submitted himself to the bite of the American species (*Eurypelma steindachneri*) several times with no more serious effect than a local inflammation. Kobert had previously reached the conclusion that neither the Italian nor the Russian tarantula bite was dangerous to human beings. (See Kobert, *Giftspinnen*, 1901; also *J. A. M. A.*, 1920, lxxiv, p. 479 and 1922, lxxviii, 1967.)

Spigelia. *U. S. IX. Maryland, Carolina* or *Indian Pink, Worm-grass, Worm-weed, American wormroot, Star-bloom.*—"The dried rhizome and roots of *Spigelia marilandica* Linné (Fam. *Loganiaceæ*), without the presence or admixture of more than 10 per cent. of stems or other foreign matter." *U. S. IX.*

Two species of *spigelia* have attracted attention as anthelmintics—*S. Anthelmia* L., of South America and the West Indies, and *S. marilandica* L., of this country. *Spigelia Anthelmia* L., of South America, is an annual plant, from one or two feet in height, with thin, shortly petioled leaves, those of the lower stem being lanceolate, those above varying from very broadly lanceolate to ovate, with a distinct tendency to a rhomboidal outline and attaining a length of over four inches. It is much used as an anthelmintic in its native country, and its rhizome is said to have appeared in the European markets. The only specimens which we have seen, however, have been the whole dried plant, of which the attached rhizomes are much smaller and the rootlets much finer than in the North American species. It is affirmed that in overdoses this rhizome is a powerful poison, which has caused death not only in the domestic animal but also in man.

The *S. marilandica* is an herbaceous perennial plant. The stems, several of which rise from the same rhizome, are simple, erect, four-sided, nearly smooth, and from twelve to twenty inches high. The leaves are opposite, sessile, ovate-lanceolate, acuminate, entire, and smooth, with the veins and margins slightly pubescent. Each stem terminates in a one-sided spike, and supports from four to twelve flowers with very short pedicels. The calyx is persistent. The corolla is funnel-shaped, and much longer than the calyx, with the tube inflated in the middle, and the border divided into five acute, spreading segments. It is of a rich carmine color externally, paler at the base, and orange-yellow within. The edges of the segments are slightly tinged with green. The capsule is double, consisting of two cohering, globular, one-celled portions, with many seeds.

The plant is a native of our Southern and Southwestern States, being seldom found north of the Potomac. It grows in rich soils on the borders of woods, and flowers from May to July. The commercial supplies being restricted, some attention has been given to the cultivation of the plant. The Bureau of Plant Industry, U. S. Department of Agriculture, Washington, D. C., has grown spigelia under shade, and Miss Henkel states that it is readily cultivated in Georgia. (*D. C.*, lvi, p. 132.)

It was at one time largely substituted by *Ruellia ciliosa* Pursh. Sanders reported examining 57 samples of pink-root which were obtained from various sections of the country and none were genuine. (*Jour. A. Ph. A.*, 1912, p. 502.) To Prof. Greenish (*A. J. P.*, 1891, p. 226) belongs the credit for the first pharmacognostic description of this common substitute, although he incorrectly attributed it to *Phlox carolina* L. (*P. ovata* L.). He pointed out that it was distinguished by the fact that it contained stone cells and cystoliths of calcium carbonate. Greenish's work was confirmed by Holm (*A. J. P.*, 1906, p. 553), and by Stockberger (*Ph. Rev.*, 1907, p. 2). His false identification continued in literature for several years, probably owing to the statements of the large drug houses which make a specialty of collecting American drugs. (*Proc. A. Ph. A.*, 1909, p. 1171.) The presence of *Phlox ovata* L. in commercial lots of spigelia has not been confirmed, and Kraemer illustrates the pharmacognosy of the rhizome and roots of this drug in *A. J. P.*, 1910, p. 470. Moser, however, affirms that *Phlox ovata* and *P. glaberrima* L. are frequently collected and sold as spigelia. (*A. J. P.*, 1909, p. 576.) Among some of the adulterants which have been identified are the rhizomes of goldenseal and caulophyllum, although a large variety of rhizomes are no doubt more or less intermixed.

Pinkroot was officially described as "rhizome horizontal or slightly oblique, more or less flexuous, somewhat branched, from 1.5 to 5 cm. in length and from 2 to 5 mm. in diameter; externally dark brown, slightly annulate, with scars of bud scales, the upper surface knotty from approximate stem-bases, bearing cup-shaped scars; from the lower and lateral portions arise numerous, long, rather coarse, sparingly branched, brittle roots; fracture short, internally differentiated into three nearly equal zones of pith, wood and bark; odor slightly aromatic; taste bitter, pungent. Few if any of the roots exhibit thin, terminal portions with the bark stripped from the slender strands of wood. Stems usually attached to the upper portion of the rhizome, nearly cylindrical, attaining a length of 6 cm. and a diameter of 3 mm., light grayish-brown to purplish-brown, nodes annulate, marked by opposite leaf-scars. Under the microscope, transverse sections of the rhizome of Spigelia show a dark brown, more or less exfoliated epidermal layer; a cortex composed of from 10 to 15 rows of starch-bearing parenchyma; a distinct zone of sieve tissue from 0.075 to 0.15 mm. in width; a compact woody area composed of tracheæ and tracheids which are hardly distinguishable from each other, both kinds of vessels being marked with bordered pores; an internal sieve closely resembling the sieve in the bark; and a pith composed of fairly uniform, nearly polygonal, thin-walled cells, more or less filled with small starch grains. Transverse sections of the root show a large cortex, the cells of which are more or less filled with small starch grains and a central stele of 6 or 8 radial fibrovascular bundles, which in the older roots are united by a strong development of lignified cells. The stem in transverse section is distinguished from the rhizome by a narrower woody zone, the tracheæ having spiral thickenings, and by a nearly uninterrupted circle of non-lignified bast-fibers in the bark. The powder is grayish-brown; when examined under the microscope it exhibits starch grains generally numerous, at times, however, few, spherical or slightly angular, from 0.002 to 0.006 mm. in diameter; fragments of lignified tracheæ and tracheids conspicuous; fragments of tracheæ with spiral thickening relatively few, bast-fibers few, very long, non-lignified; occasional fragments of the reddish-brown epidermal cells. Spigelia yields not more than 10 per cent. of ash." *U. S. IX.*

It contains a volatile alkaloid, *spigeline*, discovered by Dudley in 1881. Spigeline yields a brownish-red precipitate with a solution of iodine in potassium iodide, a white crystalline precipitate with potassio-mercuric iodide, and a white flocculent precipitate with meta-tungstic acid. Boorsma (*P. J.*, 1898, 89) found 0.0005 Gm. of spigeline to be lethal to guinea pigs. It is questionable, however, whether the vermifuge properties of pink-root are to be attributed to spigeline.

The activity of spigelia is somewhat diminished by time. Spigelia is especially esteemed against the *round-worm.* In the ordinary dose it usually produces little sensible effect on the system; more largely given it acts as a cathartic, though unequal and uncertain in its operation; in overdoses it is said to cause vertigo, dimness of vision, dilated pupils, spasms of the facial muscles and of the eye-lids, and even general convulsions. H. A. Hare (*Med. News*, March, 1887) has found that in the lower animals it produces symptoms similar to those just described. The narcotic effects are said to be less likely to occur when the medicine purges, and to be altogether obviated by combining it with cathartics. The danger from its employment cannot be great, as it was formerly largely used in the United States, in both regular and domestic practice, and serious consequences were almost unheard of. Its effects upon the nervous system have been erroneously conjectured to depend on other roots sometimes mixed with the genuine. It is usually combined with senna or some other cathartic, to insure its action on the bowels.

Dose, of the powdered root, for an adult, one or two drachms (3.9–7.7 Gm.), to be repeated, morning and evening for several days successively, and then followed by a brisk cathartic.

Spilanthes. *Spilanthes Oleracea* L. (*S. Acmella* Murr.) *Para Cress. Cresson de Para*, Fr. *Parakresse*, G. (Fam. *Compositæ.*)—A plant of the tropics used as a masticatory for *toothache;* when chewed it produces a copious salivation. (*A. J. P.*, xliv, 323.) It is cultivated both as an ornament and for its pungent leaves which are used as a salad.

Spiracin. *Methyl-carboxyl-salicylic Acid.*—It forms a white crystalline powder, insoluble in water. It is used for the same purposes as the salicylates in *doses* of ten to fifteen grains (0.6–1 Gm.).

Spiræa.—A genus of deciduous shrubs belonging to the *Rosaceæ* which are cultivated for their handsome flowers. Many if not all of the species of this genus contain a colorless volatile oil, very similar to the oil of gaultheria, but composed mainly of salicylic aldehyde, with only smaller amounts of methyl salicylate. The species which have been submitted to actual analysis are the *Spiræa Ulmaria* L. (*Filipendula Ulmaria* (L.) Maxim.), commonly known as *Queen of the Meadow*, or *Meadow-sweet*—a European plant which has been introduced into this country; also the European species *S. lobata* Jacq. and the species *S. Filipendula* L. (*Filipendula vulgaris* Moench.), which grows in Southern Europe and Northern Africa. *Spiræaic acid* (now recognized as salicylic acid) (*J. Pr. Chem.*, xix) was separated from the flowers of *S. Ulmaria* by Löwig and Weidmann, and has been found by Rochebrune in the flowers of *S. Filipendula* L.

The roots of probably most of the species contain tannic acid, gallic acid, and when fresh some of the volatile oils. (*A. J. P.*, 1887.) The root of *Spiræa tomentosa* L. (*Hardhack, Steeplebush*, or *Whitecap*), was formerly recognized in the U. S. Pharmacopœia. It is an indigenous shrub growing in low grounds from New Brunswick and Nova Scotia to the mountains of Georgia and westward. The stems and lower surfaces of the ovate-lanceolate, serrate leaves are whitish and tomentose. The rose-colored flowers are disposed in terminal, compound, crowded racemes.

The flowers of *Spiræa* possess to a very feeble extent the medicinal virtues of salicylic acid, and have been used as diuretic and tonic in the form of decoction. The roots are astringent, and have been used in the treatment of *diarrhea* in *doses* of from five to twenty grains (0.32–1.3 Gm.) of the aqueous extract repeated *pro re nata.*

Spiroform. *Vesipyrin. Acetyl Salol. Acetylphenyl-o-oxybenzoic Acid. Phenyl Acetylsalicylate. Acetyl Salicylic Phenyl Ester.* $C_6H_4(OCH_3CO)$-$COOC_6H_5$.—A tasteless, odorless powder, insoluble in water, readily decomposed by alkalies. This substance acts in the body much like phenyl salicylate; it passes through the stomach unchanged, but is broken up in the intestines, liberating salicylic acid. It was originally introduced as a urinary antiseptic, but has also been employed as an antirheumatic and analgesic. The *dose* is from eight to fifteen grains (0.5–1.0 Gm.).

Sponge. *Spongia. Spongia officinalis. Eponge*, Fr. *Schwamm. Badeschwamm*, G.—Sponges are fixed, flexible, polymorphous, diploblastic, invertebrate animals belonging to the phylum *Porifera.* The majority of sponges are marine, only about thirty species inhabiting fresh water. The sponges of commerce represent skeletons of these animals. Sponges vary greatly in their habit of growth which is responsible for their shape. Some are branched like plants; others are vase-shaped, cup-shaped, fan-shaped, or dome-shaped. Their bodies vary in size from that of a pin-head to over five feet in height, and in color from white or gray to that of every hue in the spectrum. The body-wall is constructed of two layers of cells, *viz.*, the outer or dermal epithelium and the inner or gastral epithelium. Between these is a jelly-like substance containing amœboid cells. In the simplest sponges, such as *Grantia*, a hollow central or gastral cavity opens to the exterior by a single large exhalant opening called the osculum. Numerous water pores or inhalent openings are scattered over the dermal epithelium which communicate with radial canals (a portion of which open into the gastral cavity) and, like the gastral epithelium, are lined with flagellated cells, the flagella of which beat constantly, creating a current of water. Water, containing minute organisms upon which the sponge feeds, is thereby induced to pass through the water pores into the radial canals and thence into the gastral cavity and out through the osculum. Through this system of canals, also, oxygen is distributed, waste matters eliminated and fertilization of eggs effected.

The bodies of sponges collected for commerce represent complex colonies of this simple type. The skeleta of sponges vary from spicules of silicon or carbonate of lime to fibers of a horny substance, chemically allied to silk and called *spongin*. The latter is secreted by cells of the dermal epithelium and makes up entirely the commercial sponge when purchased.

Sponges inhabit the bottom of the sea, where they are fixed to rocks or other solid bodies, and are most abundant within the tropics. They are collected chiefly in the Mediterranean and Red Seas, the West Indies and the coast of Florida and Central America. In the Grecian Archipelago, Crete, Cyprus, on the coast of Asia Minor, Syria, Barbary and the Bahama Islands, sponge fisheries constitute a very important industry.

Most of the sponges used in the United States come from the Bahamas and the coast of Florida but the finest bath sponges are brought from the Mediterranean, especially Turkish waters. The greatest source of the sponges sold in this country is Tarpon Springs, Florida. Key West is the next largest source. The varieties caught there in order of their commercial value are, *sheep's wool*, *yellow*, *grass*, and coarse grades including *boat* and *glove* sponges.

The cultivation of sponges has been undertaken on an extensive scale. Small fragments are cut under water from the live sponge, and fixed upon a sandy bottom by means of skewers. In three years they will have grown sufficiently to be marketable.

Sponge, as found in commerce, is in yellowish-brown masses of various shapes and sizes, light, porous, elastic, and composed of fine, flexible, tenacious fibers, interwoven in the form of cells and meshes. It usually contains numerous minute fragments of coral or stone, or small shells, from which it must be freed before it can be used for ordinary purposes. Sponge is prepared by macerating it for several days in cold water, beating it in order to break up the concretions which it contains, and dissolving what cannot thus be separated of the calcareous matter by hydrochloric acid diluted with thirty parts of water. By this process it is rendered perfectly soft, and fit for surgical use. It may be bleached by steeping it in water impregnated with sulphurous acid, or by exposure in a moist state to the action of chlorine or by alternate treatment first with a weak solution of potassium permanganate and then with an acidulated solution of oxalic acid. It is stated that sponges which have been soaked in pus and infectious matters will recover their primitive condition by soaking in a 4 per cent. solution of potassium permanganate, then in a 25 per cent. solution of official sulphorous acid, and finally thorough washing in an abundance of water. The most important constituent of the sponge is a substance known as *spongin* which is analogous to *fibröin* and *sericin* of silk but which Schlossberger has shown to be a distinct principle.

Sponges are used for mechanical purposes only. *Sponge tent* is employed for dilating sinuses. This is prepared by dipping sponge into melted wax, compressing it between two flat surfaces till the wax hardens, and then cutting it into pieces of a proper form and size. By the heat of the body the wax becomes soft, and the sponge, expanding by the imbibition of moisture, gradually dilates the wound or sinus in which it may be placed. When a conical sponge tent of uniform caliber is required, as for dilating the uterine cavity, a better plan is to cut the sponge into a conical shape while fresh and compress when moist, by winding it carefully with a fine tightly drawn cord, removing the cord when perfectly dry, and dipping the tent into melted wax, so as to get a thick coating. For other modes of preparing sponge tent, as well as of saturating the sponge at the same time with substances calculated to make a remedial impression, as phenol, alum, lead acetate, etc., see *A. J. P.*, 1868, 410; 1869, 446.

Spongia Usta. *Burnt Sponge.*—This was formerly official (*Spongia Usta*, U. S., 1850). Its medicinal value was due chiefly to the iodine content and it has been replaced by more reliable preparations of this element. For method of preparation, analysis, and therapeutic properties, see 16th edition, *U. S. D.*

Statice. *Statice Limonium* (L.) Gray. [Now *Limonium carolinianum* (Walt.) Britt.] *Sea Lavender. Marsh Rosemary. Ink Root. Rosmarin des Marais, Lavande triste*, Fr. *Strandnelke*, G. (Fam. *Plumbaginaceæ.*)—It is an indigenous maritime plant with a perennial, very astringent root, sending up annually tufts of leaves, which are obovate or cuneiform, entire, obtuse, mucronate, smooth, and on long foot-stalks. The small lavender colored flowers appear in panicles of spikes.

Marsh rosemary grows in the salt marshes along the sea coast from Labrador to Texas, and flowers from July to September. The root, which was formerly in the Secondary List of the U. S. Pharmacopœia, is large, spindle-shaped, or branched, fleshy, compact, rough, and of a purplish-brown color. It is bitter and extremely astringent, but odorless. It contains tannic acid (12.4 per cent.), volatile oil, resin, and other substances. *Statice* is powerfully astringent, and in some parts of the United States, particularly in New England, was much employed, especially as a local application, in decoction, to aphthous and ulcerative affections of the mouth and fauces.

In Brazil and Buenos Ayres the roots of *S. brasiliensis* Boiss. are employed under the name of *Buaycura* or *Guaycura*. For a description of the physical and chemical characteristics of the root, see *P. J.*, 1884, xv, 86. In Russia and Spain the very large roots of *S. latifolia* Sm. are used for tanning, and in Morocco the roots of *S. mucronata* L. are stated to be employed, under the name of *safrifa*, as a nervine.

Stibenyl.—Acetyl para-amino phenyl stibinate of sodium, also known as *stibacetin*. This compound is employed in the treatment of *kala-azar*. According to Klippel (*B. Hop. Par.*, 1922, xxxviii, p. 76) it has marked superiority over antimony tartrate and may be given intravenously in doses of 0.05 to 0.2 Gm. one to three grains (0.06–0.2 Gm.) every alternate day.

Sticta. *Lungmoss. Lungwort.*—The lichen *Sticta pulmonaceæ*, a native of Europe, has been used as a folk remedy in the treatment of *pulmonary complaints*. It owes its activity chiefly to *stictic acid*, which is bitter and possesses a powerful astringent action.

Stipa. *Feather Grass.*—According to Gillespie (*B. M. J.*, Oct., 1898), a number of species of this genus of grasses are actively poisonous, and have caused death in horses and other domestic animals. Of such character especially are *Stipa viridula* Trin., *Stipa inebrians* Hance, and *Stipa sibirica* Lam., of the Russian steppes. A few experiments made with *Stipa viridula* Trin., a plant growing in the prairies and meadows from western Minnesota to the Dakotas and southernward, indicated that it acts powerfully upon the brain and spinal cord.

Stipa Vaseyi Scribner.—According to Vernon Bailey this grass, which grows on the mountains of California, is a very active narcotic, producing in animals, which graze upon it, sleep lasting for a week or longer. (See Farwell, *Merck's Rep.*, 1911, p. 271.)

Stipa tenacissima L. *Esparto Grass.*—The leaves of this grass furnish a valuable fiber from which paper, ropes and mats are manufactured.

Stovaine. *N. N. R.* 1924. *Benzoyl-dimethylamino-ethylpropanol Hydrochloride*, $CH_3CH_2C(C_6H_5COO)(CH_3)CH_2N(CH_3)_2HCl$.—It is closely related to alypin. It crystallizes in small, brilliant scales, melting at 175° C., and is very soluble in water. It shows most of the reactions of cocaine, which is also a benzoyl derivative.

This substance which has been advertised by methods approaching that employed by the mountebank has been used as a local anesthetic especially for the production of the so-called *spinal anesthesia* by a very large number of surgeons. In the experiments of LeBrocq (*B. M. J.*, March 27, 1909) it was found that if the toxicity of cocaine represented 1 that of stovaine would be 0.625 and that of eucaine 0.414; in other words it stands midway between cocaine and eucaine in danger. He also found that it was locally irritant, its injection being followed by intense hyperemia and even local sloughing. As confirmatory of this local irritant effect are the changes which have been found in the spinal cord from its lumbar injection. Pauterier and Simon (*Bull. Hop. Par.*, 1907) report a case of meningitis following spinal anesthesia with the agent and Spiller and Leopold (*J. A. M. A.*, 1910, liv, p. 1840) caused intense degeneration of the posterior columns of the cord by repeated injections in the lower animals. In 1907 Chaput (*Press. Med.*, 1907) collected statistics of 3174 spinal anesthesias with stovaine with six deaths, mortality of about one in 530. In the same year, however, Torrance collected 5532 cases with but 3 deaths. Boyd and Young (*J. A. M. A.*, 1917, lxviii, 601) have reported over 6000 cases with three deaths. It is evident that the mortality of spinal anesthesia from stovaine is higher than that of general anesthesia with ether or chloroform. Schwarz (*Cb. C.*, 1907) reported signs of renal irritation in 78 per cent. of cases anesthetized by this method, but Hosemann (*Cb. C.*, 1908, xxxv, 60), in a series of sixty cases, noted mild irritation of the kidney in only ten cases, in none of which was there permanent injury. It has, however, a field of distinct value, not as a routine measure, but in certain conditions where the volatile anesthetics are unusually dangerous.

As a local anesthetic stovaine has the advantage over cocaine of being somewhat less toxic, of not dilating the pupil or causing vascular constriction, and of withstanding boiling temperatures. LeBrocq (*B. M. J.*, 1909, i, 783) found that the toxicity of stovaine was approximately two-thirds that of cocaine which conclusions correspond approximately with those of Eggleston and Hatcher (*J. P. Ex. T.*, 1919, xiii, p. 433) as applied to the intravenous injection, but the latter find that when injected subcutaneously the difference in toxicity was still more favorable for stovaine. Weight for weight, it is one of the most powerful anesthetics of all the cocaine substitutes, according to LeBrocq, surpassing even cocaine itself. For local anesthesia it is generally employed in a 1 per cent. solution of which sixteen to fifty minims (1–3 cc.) may be injected, according to the size of the area it is desired to render insensible. For spinal anesthesia it is recommended to be used in strengths of from 3 to 10 per cent., injecting a quantity of this solution equivalent to from 0.032 to 0.065 Gm. of the drug.

Strontium. Sr. = 87.63.—*Strontium* belongs to the alkaline earth group of metals along with barium and calcium. It is a yellow metal, of the sp. gr. 2.5, somewhat harder than lead, and is sufficiently malleable to be hammered out into thin plates. It oxidizes quickly on exposure to air, and hence must be kept under naphtha, like the alkali metals.

For method of preparing strontium free from barium see *U. S. D.*, 20th ed., p. 1066.

A number of salts of strontium were formerly official but all of them have been dropped from the U. S., but the Br. recognizes the bromide. They impart a bright red color to the non-luminous flame and *strontium nitrate* is largely used for making *red fire* in pyrotechnics.

At one time the strontium salts were deemed to be highly toxic, but in 1890 Laborde (*C. R. S. B.*, 1890, ii) showed that this belief was due to the fact that the earth had been contaminated with barium salts and that pure strontium was no more injurious than potassium. When a salt of strontium is taken by the mouth probably only small amounts of the metal are absorbed. The fact that it is excreted chiefly by the intestinal glands (Mendel and Thatcher, *A. J. Phys.*, 1904, xi, 5) makes it difficult to determine whether the salt found in the feces has been absorbed and re-excreted, or whether it is simply due to non-absorption. Even after hypodermic administration only traces of the metal appear in the urine. Wood and Arnold (*Phila. Monthly Medical Journal*, April, 1899) have shown that when introduced into the blood stream the strontium salts exercise a marked stimulating effect upon both the heart and arterial muscles, which are secondarily depressed by toxic doses. It causes also an increase in the contractions of the voluntary muscles with delay in their relaxation. Taken by the mouth, however, it is so slowly absorbed that it is improbable that enough can be introduced into the system to exercise any influence. According to Mendel and Thatcher, small quantities are stored up in the bones replacing a part of the calcium.

The salts of strontium, especially *strontium lactate*, were at one time extensively employed in the treatment of *chronic Bright's disease.* The remarkable claim was made for them that not only did they have a valuable diuretic effect, but that they exercised a beneficial effect upon the kidney, causing marked diminution in the excretion of albumin. Later experience, however, has not justified the earlier enthusiasm, and the use of the metal, except as a carrier of therapeutically active acids, has almost dropped out of vogue. By some it is believed that the strontium salts are less liable to disturb digestion. Especially has this been urged in regard to the salicylate, but in the experiments of Blankenhorn (*J. A. M. A.*, 1916, lvi, 331), there was no difference in the effects of the strontium and sodium salicylate.

Strontium Acetate. $Sr(C_2H_3O_2)_2 + \frac{1}{2}H_2O$.—This is a white crystalline powder, soluble in water. It is said to possess anthelmintic properties. It is given in *doses* of from ten to thirty grains (0.65–2.0 Gm.) twice a day.

Strontium Arsenite. $Sr(AsO_2)_2 + 4H_2O$.—A white powder soluble in water of somewhat variable composition representing approximately 53 per cent. of arsenic trioxide. It possesses the therapeutic virtues of arsenic, but has no advantages over the official preparation. The *dose* is from one-thirtieth to one-fifteenth of a grain (0.002–0.004 Gm.).

Strontium Carbonate. *Strontii Carbonas.* $SrCO_3 = 147.63$.—This salt has been dropped from the N. F. It was formerly described as follows:

"Strontium Carbonate occurs as a white powder, odorless and tasteless. It is insoluble in water; dissolved with effervescence by diluted hydrochloric, nitric, or acetic acid; the addition of diluted sulphuric acid to these solutions produces a white precipitate.

"*Assay.*—Dissolve about 1.5 Gm. of Strontium Carbonate, dried to constant weight at 100° C. and accurately weighed, in 30 cc. of normal hydrochloric acid V.S. and titrate the excess of acid with normal sodium hydroxide V.S., using methyl orange T.S. as indicator. It shows in the dried salt not less than 99 per cent. of $SrCO_3$.

"Each cc. of normal hydrochloric acid V.S. consumed is equivalent to 0.07381 Gm. of $SrCO_3$. Each gramme of Strontium Carbonate requires not less than 13.4 cc. of normal hydrochloric acid V.S." *N. F. IV.*

It should be free from barium as shown by lack of turbidity when a solution, made by the aid of acetic acid, is treated with potassium dichromate T.S.

It is not used medicinally, but was introduced into the N. F. for the preparation of the compound elixir of formates.

Strontium Iodide. *Strontii Iodidum. U. S. IX. Iodure de Strontium*, Fr.; *Strontiumjodid*, G.—"It contains not less than 99 per cent. of $SrI_2 + 6H_2O$ (449.57). Preserve it in small, amber-colored, glass-stoppered bottles, carefully protected from light." *U. S. IX.*

This salt was dropped at the tenth revision of the U. S. P. It was described as follows:

"Strontium Iodide occurs as colorless, transparent, hexagonal plates, as a white, granular powder, or in crystalline crusts; odorless, and having a bitter, saline taste. It is deliquescent, and is colored yellow by exposure to air and light. One Gm. of Strontium Iodide dissolves in about 0.2 mil of water at 25° C.; soluble in alcohol; slightly soluble in ether. Its aqueous solution (1 in 20) is neutral or slightly alkaline to litmus. When cautiously heated, the crystals melt and gradually lose their water of crystallization. At a red heat, the salt is decomposed, losing iodine and leaving a residue of strontium oxide. To a non-luminous flame it imparts a crimson color." *U. S. IX.* It gives the characteristic tests for strontium and for the iodides. It should not show a turbidity with potassium dichromate T.S. (absence of barium). "Gently heat 5 mils of an aqueous solution of the salt (1 in 10) with 1 drop of ferrous sulphate T.S., 1 drop of ferric chloride T.S., and 0.5 mil of potassium hydroxide T.S.; no blue color appears after acidulating the mixture with hydrochloric acid (*cyanide*). An aqueous solution of the salt does not respond to the Test for heavy metals (see Part III, Test No. 3). Dissolve 0.3 Gm. of the salt in 5 mils of distilled water, add an excess of silver nitrate T.S. and a few drops of nitric acid; filter, digest the precipitate with 5 mils of ammonia water and filter. On saturating the filtrate with nitric acid, not more than a slight turbidity is produced (*chloride* or *bromide*).

"*Assay.*—Proceed as directed under the Assay for iodides (see Part III), using about 1 Gm. of Strontium Iodide, accurately weighed. It shows not less than 99 per cent. of $SrI_2 + 6H_2O$.

"Each mil of tenth-normal silver nitrate V.S. used corresponds to 0.022478 Gm. of $SrI_2 + 6H_2O$. Each gramme of Strontium Iodide corresponds to not less than 44 mils of tenth-normal silver nitrate V.S." *U. S. IX.*

Strontium iodide has been brought forward as a means of obtaining the alterative influence of an iodide without irritating the intestinal tract or depressing the general nutrition. It contains about 56.5 per cent. of iodine, and, although its practical advantage is doubtful, may be substituted for potassium iodide in various diseases.

Dose, five to fifteen grains (0.32–1.0 Gm.).

Strontium Lactate. *Strontii Lactas. U. S.* 1890. $Sr(C_3H_5O_3)_2.3H_2O = 319.76$.—This salt may be prepared by the process of Thumann. (See *U. S. D.*, 19th ed., p. 1661.) *Strontium lactate* is "a white, granular powder, or crystalline nodules, odorless, and having a slightly bitter, saline taste; permanent in the air. Soluble in about 4 parts of water at 15° C., and in less than 0.5 part of boiling water. The solution saturated at a boiling heat remains liquid for many hours, even after being cooled to 0° C. Soluble in alcohol. When heated to 110° C., the salt loses its water (16.9 per cent.). At a higher temperature it first fuses, then is decomposed, giving off inflammable vapors, and leaves a residue of strontium carbonate and carbon, which, on the addition of hydrochloric acid, effervesces and communicates an intense, red color to a non-luminous flame. The aqueous solution (1 in 20) is slightly acid to litmus paper." *U. S.*, 1890. It gives the characteristic reactions of the soluble salts of strontium and the lactates. The absence of barium may be shown by potassium dichromate T.S., which should produce no turbidity. For further tests of purity, see *U. S. D.*, 19th ed., p. 1662.

Strontium lactate was originally brought forward by J. V. Laborde, who found it to have a distinct diuretic action. It enjoyed for a period a considerable popularity in the treatment of *nephritis* and chronic *albuminuria*. The experiments, however, of Wood and Arnold (*Phila. Monthly Med. Journ.*, April, 1899) have shown that only infinitesimal amounts of the drug are absorbed from the intestines. Upon the intestinal canal the lactate is asserted to exert a very favorable influence. Strontium lactate has also been tried with alleged good results in the treatment of *rheumatism* and *gout*, it being affirmed that it increases the nitrogenous elimination and causes disappearance of the urates. *Dose*, from ten to thirty grains (0.65–2.0 Gm.) three times a day in solution.

Strontium Phosphate. $Sr_3(PO_4)_2$.—A white, tasteless powder, soluble with decomposition in acids. Nutritive and tonic. It is used in the treatment of *phthisis* and other wasting diseases, as a tissue builder, asserted to be superior to calcium phosphate. (Labordé.) *Dose*, ten to thirty grains (0.6–2.0 Gm.).

Strontium Sulphide. *Strontii Sulphidum.* SrS. —This substance has been used to some extent as a depilatory, in accordance with the following method: A powder of 2 parts strontium sulphide, 3 parts of zinc oxide, and 3 parts of powdered starch, kept dry until used, is formed into a paste with warm water and allowed to remain upon the surface from which the hair is to be removed from one to five minutes, being taken off so soon as pronounced pain or any evidences of caustic action are perceptible. The surface should then be gently but firmly scraped with a blunt edge like that of a paper knife, then washed well with warm water, and treated with an emollient.

Strychnine Salts.—There have been from time to time placed upon the market various salts of strychnine as substitutes for those official. There is no reason, however, to believe that any of these have advantages over the pharmacopœial compounds. The amount of acid radicals represented in such compounds is usually so insignificant that it is impossible to suppose they can modify the action of the alkaloid. There is no reason to suppose that any of these differ materially in their effects from the sulphate. They are used for the same purposes and in the same doses. The following are of sufficient commercial importance to justify a word of mention.

Strychnine Arsenate. Strychninæ Arsenas.—This has been introduced as a means of obtaining the effects of its constituents. It corresponds approximately to 62.25 per cent. of strychnine and 27.75 per cent. of arsenic acid. It has been especially praised by Coriveaud (*K. T. W.*, 1909) in the treatment of bronchial *asthma* and other pectoral complaints. The dose is one-sixtieth of a grain which may be cautiously increased to one-fifteenth (0.001–0.004 Gm.).

Strychnine Formate occurs as white crystalline powder soluble in about five parts of water.

Strychnine Glycerophosphate. *N. F. IV. Strychninæ Glycerophosphas.*—This strychnine salt "occurs in white, rhombic crystals or as a white powder; odorless; having at first a faint, sweet taste, afterward becoming intensely bitter. One gramme dissolves in about 350 cc. of water, the solution being neutral or slightly alkaline to litmus; also in about 310 cc. of alcohol; slightly soluble in chloroform, and very slightly soluble in ether. On incinerating 0.2 Gm. of the salt it yields no weighable residue. The addition of sulphuric acid to the salt produces no color, or at most only a slight yellowish coloration, but on subsequently adding a fragment of potassium dichromate a deep blue color is obtained, which changes to deep violet, then to purplish-red, cherry-red and finally to orange or yellow. Add ammonia water in slight excess to a saturated aqueous solution of the salt; a white precipitate is formed which is readily soluble in chloroform. A saturated aqueous solution of the salt, acidulated with diluted nitric acid, is not rendered more than faintly turbid on the addition of silver nitrate T.S. (*chloride*). A saturated aqueous solution of the salt, acidulated with hydrochloric acid, shows not more than a slight turbidity on the addition of barium chloride T.S. (*sulphate*). Add a slight excess of ammonia water to an aqueous solution of the salt and filter the mixture; the filtrate shows not more than a slight turbidity with magnesia mixture T.S. (*phosphate*)." *N. F. IV.*

It has no advantages medicinally over other strychnine salts.

Strychnine Hypophosphite, a white crystalline powder freely soluble in water.

Strychnine Valerate. Strychninæ Valeras, N. F. IV.—This salt was introduced into the N. F. as an ingredient of an elixir. The proportion of valeric acid present can in no way modify the action of the strychnine and both the salt and elixir have very properly been dropped. It was described as follows:

"Strychnine Valerate occurs as a white crystalline powder, having an odor of valeric acid and an intensely bitter taste. It is sparingly soluble in water, becoming less soluble on keeping, through the loss of valeric acid; soluble in alcohol or chloroform; slightly soluble in ether. Its saturated aqueous solution is neutral or slightly alkaline to litmus. Dissolve about 0.05 Gm. of Strychnine Valerate in 2 cc. of sulphuric acid; no more than a faint yellowish color appears, but on adding a fragment of potassium dichromate a deep violet color is produced which changes to orange or yellow. When sulphuric acid is added to the salt, the odor of valeric acid is evolved. Incinerate 1 Gm. of Strychnine Valerate; the ash does not exceed 0.1 per cent. Ten cc. portions of an aqueous solution of the salt (1 in 100) are not affected at once by barium chloride T.S. when acidulated with hydrochloric acid (*sulphate*) nor by silver nitrate T.S. when acidulated with nitric acid (*chloride*). About 0.02 Gm. of the salt, moistened with nitric acid, may be colored yellow, but not red or reddish (*brucine*)." *N. F. IV.*

The average *dose* of strychnine valerate is given as one-fortieth of a grain (0.0015 Gm.).

Strychnos Potatorum L. fil. *Chilbinj. Clearing Nuts. Indian Gum Nuts.* (Fam. *Loganiaceæ.*) —The nuts of this species of *Strychnos* are very largely used in some parts of India for clearing muddy water. The fruit is also employed by the native practitioners of Hindostan, under the name of *nirmali*, as an emetic and in *dysentery*. They do not contain strychnine. In clearing water, one of the dried nuts is rubbed hard for a short time around the inside of the earthen water pot; on settling, the water is left pure and tasteless. The seeds contain a large quantity of an albuminous principle, upon which their virtues probably depend. They are devoid of bitterness. The tree, which grows to a very large size, produces a shining, black, one-seeded berry (that of the nux vomica being many-seeded). The seeds are broadly lenticular, about half an inch in diameter and a quarter of an inch in thickness, of a dirty whitish-gray color, and covered with a thick coating of delicate appressed hairs. These are so small that the seed to the naked eye looks mealy. Under the microscope the hairs are seen to be agglutinated in groups of from three to six, and to consist each of a single pointed cylindrical cell.

Stylophorum. *Stylophorum diphyllum* (Michx.) Nuttall. (Fam. *Papaveraceæ.*)—This plant, commonly known as "*Celandine Poppy*," is found in damp woods from western Pennsylvania to Wisconsin and Tennessee. In its foliage and flowers it resembles *Chelidonium majus.* According to E. Schmidt, the root contains *chelidonine,* with a second alkaloid closely related to, if not identical with, *chelerythrine.* (*A. J. P.*, 1888.)

Stylosanthes. *Stylosanthes biflora* (L.) B. S. P. (Fam. *Leguminosæ.*)—This low, branching perennial has wiry stems, 3-foliate leaves and small yellow flowers. It is found in the pine barrens and dry soil of the eastern and central United States and it is asserted that it possesses the power of relieving abdominal uterine pains during the latter months of gestation, and is also a uterine tonic during parturition. *Dose,* of the fluidextract, from ten to twenty minims (0.6–1.3 cc.) three times a day.

Styrone. *Cinnamic Alcohol. Styryl Alcohol.* $C_6H_5.CH : CH.CH_2.OH$.—A *beta-phenyl-allyl alcohol* appearing either as an aromatic oily fluid, boiling at 250° C., or a crystalline solid, forming white needles soluble in alcohol and fusing at 25° to 35° C. The fluid is used in *otitis media* and the crystals as a deodorant and antiseptic either in the dry form or in a glycerin solution.

Subcutin.—This compound of paraphenolsulphonic acid with paramido-benzoic acid has been brought forward by Ritsert as non-toxic, distinctly germicidal, and locally anesthetic. It is a white, crystalline powder, soluble to the extent of 1 per cent. in cold water, and two and one-half per cent. in tepid water. For hypodermic use to this solution is added about 1 per cent. of ordinary salt. It is stated that it is especially adapted to the production of infiltration anesthesia but Recke has shown that its anesthetic power is relatively low.

Sublamine. *Hydrargyri Sulphas Æthylenediaminata. Ethylene-diamine-mercury Sulphate. Mercamin.* $HgSO_4.2C_2H_4(NH_2) + 2H_2O$.—This is a white powder, soluble in water, composed of one molecule of mercuric sulphate and two molecules of ethylenediamine, and represents about 43 per cent. of mercury. It was originally brought forward as a non-irritant germicide of exceptional penetrative power, and especially useful for the purpose of disinfecting the hands and skin; used in solution varying from 1 to 1000 up to 1 to 200. It has also been highly commended in 1 to 300 for sterilizing suture silk by boiling.

Sublamine has also been employed to some extent for the hypodermic administration of mercury; it is affirmed by Schuftan, when given hypodermically, to be more active than corrosive sublimate, probably because it does not coagulate albumin. It is incompatible with sodium chloride and should not be exposed to the air.

Succinic Acid. *Acidum Succinicum. Sal Succini Volatile. Acide succinique,* Fr. *Bernsteinsäure,* G. $COOH(CH_2)_2COOH$.—This acid was originally obtained by distilling amber but is now prepared by fermenting ammonium tartrate solution with a specific micro-organism. The product was formerly an aqueous solution of *succinic acid,* associated with empyreumatic oil. (See *Amber.*) By filtering the liquor the solution of the impure acid passes through, while the oil was absorbed by the paper. The acid was purified by boiling the solution with nitric acid, diluted with twice its bulk of water, and then evaporating to crystallize: Succinic acid is made artificially by the action of nitric acid on the fatty acids, and may be produced in a great many ways from various substances. Thus, it is invariably formed in small amount in the alcoholic fermentation of sugar and also in the putrefaction of a variety of fats. For other methods see *U. S. D.*, 20th ed., p. 1627, xxvii.

Succinic acid, when pure, is in white, transparent crystals having no odor and a somewhat acrid taste. It dissolves in five times its weight of cold and twice its weight of boiling water. It is less soluble in alcohol and very sparingly so in ether. Nitric acid is without action on it. It melts at 182° C., and boils without alteration at 235° C. It sublimes, however, at a much lower temperature. According to Wackenroder, it is sometimes adulterated with tartaric acid soaked in oil of amber. Succinic acid, though formerly official, is at present seldom used in medicine. One of its salts, *ammonium succinate,* $(NH_4)_2C_4H_4O_4$, made by supersaturating succinic acid with ammonia, evaporating and crystallizing, has been used with alleged great success in *delirium tremens.* This salt is occasionally used as a precipitant of ferric oxide. See also *Sodium Succinate.*

Sulphaminic Acid. *Amido-sulphonic Acid.* NH_2SO_2OH.—This occurs as colorless crystals, freely soluble in water. Emmerich (*M. M. W.*, 1912), on the theory that the irritant toxin of *cholera* is nitrous acid, recommended the use of *sulphaminic acid* in the treatment of this disease. A tablespoonful of a one per cent. solution may be given every hour.

Sulphanilic Acid. $C_6H_4(NH)_2(HSO_3)$ 1 : 4. *Para-amino-benzene-sulphonic Acid.*—It occurs as colorless crystals, slightly soluble in water, insoluble in alcohol or ether and efflorescent in the air. Internally it has been recommended in the treatment of chronic *catarrh* in *doses* of 10 to 30 grains (0.6–2.0 Gm.), although it is of doubtful value. Its most important use is in Ehrlich's diazo-reaction for typhoid urine. Under the name of *Nizin,* tablets containing 0.13 gramme of sulphanilate of zinc are marketed and asserted to possess both astringent and antiseptic properties.

Sulpharsphenamine. *Sulfarsenol. Disodium-diamino-dihydroxyarsenobenzene-dimethylene Sulphonate. N. N. R.*—Sulpharsphenamine is a light yellow powder freely soluble in water forming solutions ranging from yellow to orange, according to their concentration, and acid to litmus. Solutions of 10 per cent. and over after standing for some days form a yellow jelly, but there is no apparent change takes place in dilute solutions. The average content of arsenic is about 22 per cent. Sulpharsphenamine was brought forward by Voegtlin (*J. P. Ex. T.*, 1920, xvi, 199 and 449) as a substitute for arsphenamine. He claims that its spirocheticidal power is at least equal to arsphenamine and that its toxicity is decidedly less than that of the older drug. He also finds (*U. S. Pub. Health Rep.*, May 11, 1923) that in cases of cerebrospinal *syphilis* it is decidedly more efficient than arsphenamine. While the clinical reports of its use are as yet insufficient to permit of accurate judgment of its relative value, they are numerous enough to hold forth great promise for it.

A great advantage of sulpharsphenamine is its stability in the air. Voegtlin found that solutions allowed to stand for 24 hours were not more toxic than when freshly made.

It may be used either intramuscularly, subcutaneously or intravenously. It is sold in ampules containing 0.06 to 0.6 Gm. (from one to nine grains).

Sulphoform. *Triphenylstibine Sulphide.* $(C_6H_5)_3SbS$.—According to Kaufmann (*Ber. d. Chem. Ges.*, 1908, xli), this compound liberates its sulphur with extreme ease; hydrogen dioxide causes a separation of the sulphur and oxidization to sulphuric acid, and the antimony being oxidized to antimony oxide which combines with the sulphuric acid, this reaction taking place almost quantitatively at a temperature of 36° C. He states that *sulphoform* is more than one hundred times as efficacious as ordinary sulphur as a reducing agent. Joseph (*Derm. Cb.*, 1910, xiv) has found it a very useful remedy for *seborrheic alopecia*, and also of service in *eczema* and other *skin diseases*. He uses an ointment containing from five to twenty per cent. of sulphoform.

Sulpholeic Acid.—Sulpholeic acid is prepared as follows: Castor, almond or other fixed oil is gradually mixed with 30 or 40 parts of concentrated sulphuric acid, the mixture being cooled, if necessary, with ice, to prevent a rise of temperature above 50° C. The reaction, which at first is quite violent, is allowed to go on for from six to twelve hours, after which the mixture of acid and glycerin is decanted, the residue mixed with 100 parts of water, and this, after stirring, is also decanted. A salt is then formed by the addition of a hydroxide or carbonate. From this salt pure sulpholeic acid is obtained by careful decomposition with sulphuric acid, and agitation with purified benzin or ether. (*Ph. Rund.*, 1885, p. 154.) Both the sulpholeic acid and its salts have the power of dissolving a large variety of substances, including the essential oils, sulphur, naphthol, iodoform, etc. These liquid mixtures of sulpholeates and other bodies have the property of forming emulsions or even clear solutions with water. The limit of the miscibility (in form of emulsion) or solubility varies considerably, and depends both on the degree of concentration of the sulpholeate serving as a menstruum, and on certain little understood properties of the substances mixed with it.

This peculiar behavior of the sulpholeates and particularly of the sulpho-ricinoleate of alkalies, (see *Sodium Sulphoricinate*) towards many otherwise insoluble or difficultly soluble substances, as well as their pronounced saponaceous character and the great readiness with which they take up and combine with liquids, is said to render them eminently suitable for various technical and medicinal uses.

The liquid alkaline salt which forms the solvent is termed *polysolve* by A. Mueller Jacobs, who believes that the sulpholeate mixtures will be found excellent solvents or vehicles in place of vaseline, oils, glycerin, etc., in perfumery, soap making or pharmacy. (*Am. Drug.*, 1884, p. 22.)

Sulphopyrine. *Antipyrine para-aminobenzenesulphonate. Antipyrine Sulphanilate.*—It is a white, crystalline powder, without odor, readily soluble in water, insoluble in alcohol. Although originally introduced as a substitute for antipyrine, Neumann (*All. W. M. Z.*, 1906, p. 813) has found that this drug has the power of preventing the appearance of that congery of symptoms commonly known as *iodism.* It is also used in *coryza.* The *dose* he employed was fifteen grains (1 Gm.) three times a day.

Sulphoid. *Sulfidal. Colloidal Sulphur.*—It is made by passing hydrogen sulphide through a solution of sulphurous acid and has been used in the treatment of various *skin diseases* as a substitute for the ordinary form of sulphur. According to Joseph (*Derm. Cb.*, 1907), it is distinctly superior to the insoluble forms of sulphur. In *acne* he employed a paste or ointment containing 10 per cent. of *sulphoid* and 2 per cent. of salicylic acid, in *alopecia seborrheacia* and *eczema squamosum* a 10 per cent. solution in water either with or without glycerin.

Sulphur Iodide. *Sulphuris Iodidum. U. S. VIII, Br.*, 1898. *Sulphur Monoiodide. Sulfur Iodatum. Ioduretum Sulfuris. Iodure de Soufre,* Fr. *Jodschwefel*, G.—This compound is chemically regarded as *iodine disulphide*, I_2S_2, or, as sometimes stated, *sulphur subiodide. Sulphur iodide* is in "brittle masses of a crystalline fracture and a grayish-black, metallic luster, having the odor of iodine and a somewhat acrid taste. Almost insoluble in water; soluble in about 60 parts of glycerin; very soluble in carbon disulphide. Alcohol, ether, and a solution of potassium iodide dissolve the iodine, leaving the sulphur. Continued boiling with water vaporizes all of the iodine, leaving about 20 per cent. of sulphur as residue. On exposing Sulphur Iodide to the air, it gradually loses iodine. On heating it, some iodine sublimes at first; at a somewhat higher temperature a sublimate is formed, containing both iodine and sulphur. At a still higher temperature, the whole is volatilized, leaving only a trace of residue." *U. S. VIII.* For method of preparation see *U. S. D.*, 20th ed.

It is rapidly decomposed, when in a state of powder, upon the addition of several of the volatile oils, violet vapors of iodine being evolved, and the odor of sulphur perceived. Sulphur iodide has been considerably employed as an external remedy in various skin diseases, such as *tinea capitis, lupus, lepra*, etc., applied in the form of ointment. *Ointment of sulphur iodide*, formerly official in the British Pharmacopœia, was made by mixing together 1 part of sulphur iodide, 1 part of glycerin and 23 parts of benzoinated lard. Internally, it has been used with alleged advantage in human *glanders*.

Sulphosalicylic Acid. *Salicyl-sulphonic Acid.* $C_6H_3SO_3H.OH.COOH$.—Made by acting upon salicylic acid with strong sulphuric acid. It is in the form of white acicular crystals, soluble in water and alcohol. *Sulphosalicylic acid* is used, like sodium salicylate, in rheumatism, but its chief value lies in its use as a reagent to detect the presence of proteids of all kinds. Egg-albumin (1 in 12,500) can be detected by this reagent, forming a dense, white precipitate which is not redissolved on boiling. It is used to detect albumin, peptones, globulins and fibrin. Albumoses and peptones redissolve when boiled, but again separate on cooling.

Sweet Pellitory.—The root of *Tanacetum umbelliferum* Boiss. (Fam. *Compositæ*), of India, according to David Hooper, contains pyrethrine in minute proportions with fat and wax, an organic acid which is a pigment, glucose, and inulin. (*P. J.*, xxi, 1890.)

Swietenia. *Swietenia febrifuga* Roxb. (*Soymida febrifuga* Juss.) *Rohan Bark.* (Fam. *Meliaceæ.*)—The bark of this East Indian tree contains a bitter principle and is said to be much used as an antiperiodic in half drachm (2 Gm.) *doses.* The extract is used in *dysentery* like kino.

Swietenia Mahagoni Jacq., or *mahogany tree,* which grows in the West Indies and other parts of tropical America, has also a bitter, astringent bark, containing catechin. (*Bull. Soc. Chim. Paris,* xxiv, 118.) The oil of the seeds is said to be used as a purgative in the West Indies. The bark of *S. senegalensis* Desv. (*Khaya senegalensis* A. Juss.), *Juribali bark,* is used on the coast of Africa in the cure of *intermittents,* and Caventou extracted an alkaloid from it. (*Am. J. M. S.*, N. S., xx, 168.)

Symphytum. *Symphytum officinale* L. *Comfrey. Blackwort. Briussewort. Radix Symphiti. Radix Consolidæ Majoris. Consoude,* Fr. *Schwarzwurz, Beinwurz,* G.—A perennial, European herb often cultivated. Its root is spindle-shaped, branched, often more than 2.5 cm. thick, and 3 dm. long, externally smooth and brownish-black, internally white, fleshy, and juicy. By drying it becomes wrinkled, of a firm, horny texture, and of a dark color within. It is almost inodorous, and has a sweetish mucilaginous, feebly astringent taste. Titherley and Coppin in 1912 found 0.8 per cent. of *allantoin,* $C_4H_6N_4O_3$, in the rhizome. Greimer (*A. Pharm.*, 1900, ccxxxviii, p. 505) found two poisonous alkaloids, *consolidine* and *symphytocynoglossine,* both of which are depressants to the central nervous system. Allantoin is an oxidation product of uric acid and is found normally in the excretions of some animals, but apparently cannot be synthesized by the human organism. It is also widely distributed in the vegetable kingdom.

Comfrey contains mucilage in great abundance (according to Lewis, more than althæa root), and a little tannin. It was formerly highly esteemed as a vulnerary. According to Macalister (*B. M. J.*, Jan. 6, 1912), *allantoin,* in aqueous solution in strengths of 0.3 per cent. has a powerful action in hastening epithelial formation, and is a valuable remedy not only in external ulceration, but also in *ulcers of the stomach* and duodenum. Comfrey is a demulcent, and is used domestically in *chronic catarrhs, consumption,* and other lung diseases.

Symplocos. *Symplocos racemosa* Roxb. (Fam. *Styraceæ.*)—The bark of this East Indian tree is said to be a mild astringent, and especially useful in *menorrhagia.* Hesse reported an alkaloid, *loturine,* which has since been found to be identical with *harman* $C_{12}H_{10}O_2$—a derivative of the indol group. (*P. J.*, Sept. 24, 1881.)

Syringa. *Syringa vulgaris* L. *Common Lilac.* (Fam. *Oleaceæ.*)—A large shrub with simple ovate, sub-cordate, opposite, bright green foliage leaves and thyrsoid panicles of fragrant lilac-purple or white flowers. The leaves and fruit of this common ornamental plant have a bitter and somewhat acrid taste, and have been used as tonics and antiperiodics. Petroz and Robinet found in the fruit a sweet and a bitter principle. The latter was afterwards obtained pure by Meillet, who gave it the name of *lilacïn,* and by Bernays, who called it *syringin.* Kromayer (*A. Pharm.*, (2), cxiii, 19) established its glucosidal character, gave it the formula $C_{17}H_{24}O_9 + H_2O$, and showed its identity with the ligustrin found in privet (see *Ligustrum*). It forms stellate, colorless crystals which are soluble in hot water or alcohol and fuse at 212° C. On heating with dilute acids it breaks up into *syringenin,* $C_{11}H_{14}O_4$ (which has been recognized as *oxymethyl coniferin*) and glucose. Antipyretic and antimalarial properties have been attributed to syringin.

Tacamahac. *Tacamahaca.*—These names are applied to a resinous substance which is sometimes substituted for or admixed with Elemi resin. There are two classes of these products: the West Indian, which have an odor like that of incense, and the East Indian, whose odor resembles Elemi.

The *West Indian tacamahacs* are derived from species of the *Burseraceæ. Cayenne Incense,* also called *Brazilian Elemi,* is obtained from the *Protium heptaphyllum* March (*Icica heptapylla* Aubl.) and related species (see also under *Elemi*). The most important of this group is derived from *Bursera tomentosa* Triana (*Elaphrium tomentosum* Jacq.), a tree of considerable size, of the Fam. *Burseraceæ,* growing in the island of Curaçao and in Venezuela, is in irregularly shaped pieces of various sizes. The color is usually light yellowish or reddish-brown, but in the larger masses is more or less diversified. The pieces are in general translucent, though frequently covered with powder upon their surface, so as to render them apparently opaque. They are heavier than water, brittle, and pulverizable, yielding a pale yellow powder. Their odor is resinous and agreeable, their taste bitter, balsamic, and somewhat acrid. Exposed to heat, they melt and exhale a stronger odor. Tacamahac is partially soluble in alcohol, and completely so in ether and the fixed oils. It consists of resin with a little volatile oil.

The East Indian tacamahac and called *tacamahaca orientale,* or *tacamahaca in testis,* comes into the market in gourd shells covered with rush leaves. It is of a pale yellow color inclining to green, slightly translucent, soft, and adhesive, of an agreeable odor, and an aromatic bitterish taste. It is at present very rare in commerce. The tree which yields this resin produces a drupe, about as large as a plum, from the seeds of which 50 per cent. of a greenish-yellow fixed oil is obtained by expression, which is used in India for lamps, and as a local application in the *itch.* (*J. P. C.*, 1861, 23.) Guibourt described several other varieties of tacamahac, which, however, are little known. Among them is a soft, adhesive, dark, green oleoresin (*J. P. C.*, 3e sér., xxiv, 396), said to be procured from the *Calophyllum Tacamahaca* Willd., growing in the islands of Réunion and Madagascar.

Tacamahac was formerly highly esteemed as an internal remedy, but is now used only in ointments and plasters. Its properties are analogous to those of the turpentines. It is sometimes used as incense. It is known as *Bourbon tacamahac,* also as *Balsamum* (or *Resina*) *Mariæ.*

Tachia. *Tachia guianensis* Aubl.—The root of this tree (Fam. *Gentianaceæ*) has been used under the name of *Caferana,* in Brazil, as an antiperiodic and tonic. According to Peckoldt it contains an organic, crystalline substance, *caferanine.* (See *Merck's Bericht*, 1889; also *B. Chem. G.*, 1899, No. 7.)

Taka Diastase.—This ferment discovered by Takamine is formed by the action of a fungus (*Moyashi; Aspergillus Oryzæ* Cohn., *Eurotium Oryzæ* Ahlburg; for description, see *A. J. P.*, 1898, 137) upon steamed rice, and is used in Japan, where it is known by the name of *koji*, in the preparation of the national intoxicating beverage *sake;* it has also been employed to act upon maize in the making of whisky. Taka-diastase is a yellowish-white, highly hygroscopic powder, almost tasteless, freely soluble in water. It is capable, under proper conditions, of converting one hundred times its weight of starch into glucose in ten minutes. Its action and therapeutic uses are the same as those of diastase from malt. (See *Maltum*, Part I.) It should be given in the middle of the meal, in *doses* of from five to ten grains (0.32–0.65 Gm.), in capsules; or, after the meal, in slightly alkaline solution.

Tamaquare.—A fluid preparation from a Brazilian *Myrospermum*, which is miscible with alcohol, does not dry and possesses an unctuous consistency. It is used in certain diseases of the eye, petrolatum being used as the vehicle. From a three to a ten per cent. ointment is the usual strength.

Tanghinia. *Tanguin. Ordeal Bean of Madagascar.*—The seed of the *Tanghinia venenifera* Poir. (*Cerbera Tanghin* Hook.) (Fam. *Apocynaceæ*) contains a poisonous principle, *tanghinin*, which by some has been considered identical with cerberin. It was found by Quinquaud (*Journ. de l'Anat. et de Phys.*, 1886, xxii) to exert a powerful effect on the nervous system as well as on the circulation.

Tang-kuei or **Man-mu.**—Under the name of *tangkuei* the Chinese have used for a long time a root obtained from *Angelica anomala* var. *chinensis* (Fam. *Umbelliferæ*). A fluid extract of this root has been introduced into European medicine under the name of *eumenol* and is recommended by a number of authors in the treatment of *dysmenorrhea* and other uterine complaints. Read and Schmidt (*Proc. Soc. Exp. Biol. and Med.*, 1923, xx, 395) find that tangkuei produces in the lower animals fall of blood pressure, diuresis, and stimulation of the unstriped muscles, especially the uterus. They separated a crystalline non-nitrogenous, non-glucosidal substance which had the characteristic effect upon the uterus without circulatory depression. The *dose* of this fluidextract is one tablespoonful three times a day.

Tannaphthol.—This is a condensation product of benzonaphthol with tannin albuminate. It is used as a surgical dusting powder, also in the treatment of *diarrhea* in doses of from eight to fifteen grains (0.5 to 1 Gm.).

Tannalum. *Tannal. Basic Aluminum Tannate.* $Al(OH)_2(C_{14}H_9O_9) + 5H_2O$.—This is a brownish-yellow powder, insoluble in water, which has been especially commended by Heymann as a mild, astringent, non-irritant substance, to be used as a dusting powder or by insufflation in diseases of the nasal and laryngeal mucous membranes. By the action of tartaric acid it becomes converted into the so-called *soluble tannal*, $Al(C_4H_4O_6)$-$(C_{14}H_9O_9) + 3H_2O$, also used locally.

Tannocol. *Gelatin-tannate.*—This is a tasteless, odorless powder, containing about 50 per cent. of tannic acid, having the same therapeutic properties and applications as albumin tannate. It is claimed by Rosenheim that it is superior to that substance in being cheaper, of greater constancy of constitution, and less easily affected by the gastric juices. In the intestines it is decomposed by the alkaline secretions and tannic acid is liberated. *Dose*, fifteen to thirty grains (1–2 Gm.).

Tannoform. *Helgotan. Methylene Ditannin.* $CH_2(C_{14}H_9O_9)_2$.—The condensation product of gallotannic acid and formaldehyde, is made by dissolving five grammes of tannin in about fifteen kilogrammes of hot water, adding three kilogrammes of 30 per cent. formaldehyde, and then adding concentrated hydrochloric acid until no further precipitate is thrown down. This requires about twelve to fifteen kilogrammes of acid. The precipitate is then washed with water and dried at a low temperature.

Tannoform occurs as a light, pinkish powder which decomposes at about 230° C. It is dissolved by alcohol and is insoluble in all the other usual organic solvents; but is soluble in diluted ammonia, sodium or potassium hydroxide solutions, giving a brownish-red solution, from which it is again precipitated upon the addition of an acid. When warmed with concentrated sulphuric acid it dissolves with a brown color, turning on further heating to green, and then to blue. This green or blue solution gives a blue color with alcohol, which on standing some time turns to a wine-red, and on dilution with soda solution to a grass-green color. According to Sollmann (*J. P. Ex. T.*, 1921, xvii, 94) there is considerable variation in the composition of specimens of tannoform. He finds that, generally speaking, a considerable proportion is dissolved in neutral or acid aqueous solutions but that they dissolve almost immediately and completely in alkaline solutions.

Tannoform has been used with alleged good results in *enteritis* and other forms of *diarrhea.* It is asserted that the drug is decomposed by the intestines, the tannic acid radical acting as an astringent, and the formaldehyde as an antiseptic. It is, however, more frequently employed as a local remedy in the treatment of *eczema, bed sores*, etc. In *hyperidrosis of the feet*, well rubbed in between the toes over night, it will often give relief of considerable duration, but has the disadvantage of staining the skin brown. It has also been used externally to control *night sweats. Dose*, from five to fifteen grains (0.32–1.0 Gm.), in capsule, from three to six times a day.

Tannon. *Tannopin*, $(CH_2)_6N_4(C_{14}H_{10}O_9)_3$, is a condensation product of tannin and hexamethylenetetramine. It is a light brown, tasteless and odorless, non-hygroscopic powder, insoluble in water, weak acids, spirit, and ether, but dissolving slowly in dilute alkaline solution. It has been used by Schreiber (*D. M. W.*, 1897) in *diarrhea* in *doses* of fifteen grains (1.0 Gm.) from three to four times a day.

Tansy. *Tanacetum. U. S.* 1890.—Under this name the U. S. Pharmacopœia formerly recognized the tops and leaves of the *Tanacetum vulgare* L., a perennial herbaceous plant rising two or three feet in height, which is cultivated in our gardens, although growing wild in the roads and in old fields. It was originally introduced from Europe. It is in flower from July to September.

Tansy was officially described as follows: "Leaves about 15 Cm. long; bipinnatifid, the segments oblong, obtuse, serrate or incised, smooth, dark green, and glandular; flower-heads corymbose, with imbricated involucre, a convex, naked receptacle, and numerous yellow, tubular florets." *U. S.*, 1890. The odor is strong, and characteristic, but much diminished by drying; the taste is warm, bitter, somewhat acrid, and aromatic. These properties are imparted to water and alcohol. Leppig (*Inaug Dis.*, Dorpat, 1882), found in both the flowers and the leaves a peculiar, bitter principle *tanacetin*, to which he gives the formula $C_{11}H_{16}O_4$, and which forms a very hygroscopic, brownish, amorphous mass, easily soluble in alcohol and in water, insoluble in ether. It possesses a taste at first characteristically bitter like willow bark, and then cooling and caustic. The essential oil consists of 70 per cent. of a ketone, *tanaceton*, which appears to be identical with thujone; 26 per cent. of borneol; and 1 per cent. of a terpene, boiling at 155° to 160° C. (See Semmler, *B. Chem. G.*, xxv; see also *Schim. Rep.*, April, 1893, and April, 1897; and Gildemeister and Hoffmann, *Aetherische Oele.*)

Tansy adds to the medicinal properties of the aromatic bitters those of an irritant narcotic. It has been recommended in *intermittents, hysteria,* and *amenorrhea*, but in this country is little employed in regular practice. The seeds are said to be effectual as a vermifuge. Tansy has been used to a considerable extent as a domestic abortifacient, but Macht (*J. P. Ex. T.*, 1913, iv, 547) has shown that it has no stimulating effect on the uterus.

There have been reported several fatal cases of poisoning by it. The symptoms caused by it have been abdominal pain, vomiting, violent epileptic convulsions often followed by profound coma, dilated pupils, great disturbances of respiration, frequent and feeble pulse, and death, which has been said to be from heart failure, but is probably the outcome of a paralytic asphyxia. The minimum fatal dose can scarcely be considered to have been positively ascertained, but a fluidrachm (3.75 cc.) of the oil is said to have caused death, although recovery in one case occurred after taking half a fluidounce. Tansy tea has also caused death. (For cases, see *Am. J. M. S.*, xvi, xxiii, xxiv; *J. P. C.*, April, 1870; *J. A. M. A.*, xlvii, p. 509.) Post-mortems have been reported in which no inflammation of the gastrointestinal mucous membranes could be discovered.

The *dose* of the powder is from thirty grains to a drachm (2.0–3.9 Gm.) two or three times a day; usually in the form of an infusion.

Tapioca.—Under this name the U. S. P. formerly recognized the starch grains obtained from the bitter cassava (*Manihot utilissima* Pohl), and the sweet cassava (*M. Aipi* Pohl) (Fam. *Euphorbiaceæ*). The starch is extracted from the thickened rhizome and is known in commerce by the names of *Cassava, Tapioca* or *Manioca Starch,* and as *Bahia, Rio* or *Para Arrowroot.* These plants are native to Brazil and are cultivated in other tropical or subtropical countries including both the East and West Indies.

The root of the *sweet* cassava may be eaten with impunity; that of the *bitter*, which is the most extensively cultivated, abounds in an acrid, milky juice, which renders it highly poisonous if eaten in the recent state. Henry and Boutron Chalard affirm that the bitter cassava contains hydrocyanic acid (*J. P. C.*, xxii, 119), but Peckoldt claims that its poisonous effects are due to *manihotoxine* (*Ph. Rund.*, iv, 1890). In the production of the starch from the bitter cassava the hydrocyanic acid which is present in fresh fruits is entirely eliminated by the process of washing and drying.

For description of the preparation of tapioca see *U. S. D.*, 20th ed., p. 1632; also *Ph. Era*, 1921, liv, 385.

Tapioca is in irregular, hard, white, rough grains, possessing little taste, partially soluble in cold water, and affording a fine blue color when iodine is added to its filtered solution. The partial solubility in cold water is owing to the rupture of the starch granules by heat. Examined microscopically the starch grains of cassava are rounded or truncated on one side, single or from 2 to 8 compound, 6 to 35 microns in diameter, the hilum central, circular or triangular and frequently with radiating clefts, the lamellæ indistinct, and polarization crosses very prominent.

Tapioca meal, called sometimes *Brazilian arrowroot*, and by the French *moussache*, is the fecula dried without heat. Its granules are identical with those already described. A factitious tapioca is found in commerce, consisting of very small, smooth, spherical grains, and supposed to be prepared from potato starch. It is sold under the name of *pearl tapioca.*

Being nutritious, and the same time easy of digestion and destitute of irritating properties, tapioca forms an excellent diet for the sick and convalescent. It is prepared for use by boiling it in water. Lemon juice and sugar are usually grateful additions, and in low states of disease or cases of *debility* it may be impregnated with wine and nutmeg or other aromatic.

Cassaripe is the thickened gum obtained from the root of the bitter cassava, which is said to be innocuous and so actively antiseptic as to be habitually used in Brazil for the preservation of meat. According to S. D. Risley (*Phila. Med. Journ.*, 1899), the 10 per cent. ointment of cassaripe is useful in *suppurating conjunctivitis* and *ulcers* of the *cornea*, applied with gentle massage three or four times a day.

Taxus. *Taxus baccata* L. *Yew Tree. If commun*, Fr. *Eibe*, G. (Fam. *Taxaceæ.*)—This is a handsome evergreen tree attaining the height of 60 feet, with a short trunk and broad, low crown, reddish, flaky bark, linear to falcate, dark green leaves and scarlet fruits, each of which consists of a globose disk, in which is borne an ellipsoidal brown seed. The fruit appears to be a deadly poison. In a fatal case the child was found semicomatose, with convulsions, a cold and clammy skin, difficult respirations, dilated pupils, and making attempts at vomiting. The poison is probably in the seeds. (See 16th edition, *U. S. D.* For fatal cases in adults, see *M. T. G.*, 1870, ii; also *L. L.*, 1870, 471; also *P. J.*, viii, 361.) W. Marmé obtained from yew seeds and leaves an alkaloid, $C_{37}H_{51}O_{10}N$, to which the name of *taxine* has been given. It was a white, poisonous, crystalline powder, only slightly soluble in water, easily soluble in ether, alcohol, chloroform, benzene and carbon disulphide, but not in petroleum benzin. With concentrated sulphuric acid it gave a red color, but dissolved without color in nitric and phosphoric acids. (*A. J. P.*, 1876, 353.) For Vreven's method of isolating taxine, see *P. J.*, 1896, 215. Taxine has been studied by a number of investigators notably Winterstein (*Zeit. P. C.*, 1921, cxvii, p. 240 and 1923, cxxviii, p. 175). It melts between 105° and 110° C. and is

UNIVERSITY OF ILLINOIS
LIBRARY CHEMISTRY

dextro-rotatory. Its salts are amorphous, although the base is crystalline. Amato and Capparelli (*Gazz. Chim.*, x, 349) prepared from the leaves a volatile alkaloid, which was soluble in cold sulphuric acid with yellow color, becoming red on heating. They also isolated a nitrogenous crystalline and colorless principle, fusing at from 86° to 87° C., soluble in alcohol, insoluble in water, named *milossin.*

Lefebvre (*A. Pharm.*, ccxlv, 486) has isolated from the twigs of the yew a crystalline glucoside to which he gives the name *taxicatin.* It had the formula of $C_{13}H_{22}O_7 + 2H_2O$ and a melting point of 165° C.

Tayuya.—The root of the *Dermophylla* (*Cayaponia*) *pendulina* Manso (Fam. *Cucurbitaceæ*), is used in Brazil, under the name of *tayuya,* in *syphilis*, etc. (*N. R.*, 1877, 234); also, under the same name, the root of the *Trianosperma ficifolia* Mart. (*Cayaponia Martiana* Cogn.) (*P. J.*, x, 667), and probably various other roots. In *C. ficifolia* Cogn. two alkaloids, *trianospermine* and *trianospermitine,* and a bitter principle, *tayuyin,* have been found by Peckoldt (*P. J.*, x, 667), and in *T. dermophylla* a green resin, bitter extractive, and tannic acid were found by the same investigator. (*B. G. T.*, lxxxiv, xci. See also *Proc. A. Ph. A.*, xxiv.)

Tea. *Thé*, Fr. *Thee*, G.—The plant which furnishes *tea*—*Thea sinensis* L. (*Camelia Thea* Link) (Fam. *Theaceæ*)—is an evergreen shrub. It has numerous alternate branches, furnished with elliptic-lanceolate, or obovate-lanceolate, short-petiolate, acuminate leaves, which are serrate except at the base, smooth on both sides, occasionally pubescent beneath, green, shining, pinnately veined and having a prominent midrib. They are two or three inches long, and from half an inch to an inch in breadth. The flowers are either solitary or supported, two or three together, at the axils of the leaves. They are of considerable size, not unlike those of the myrtle in appearance, consisting of a short green calyx with five or six lobes, of a corolla with from four to nine large unequal snow-white petals, of numerous stamens with yellow anthers and connected at their base, and of a pistil with a three-parted style. The fruit is a three-locular and three-seeded capsule.

There are two principal varieties of *T. sinensis,* viz. *viridis* Pierre (*T. viridis* L.), which is a large spreading shrub, having light green lanceolate leaves from 12 cm. long to 4 cm. wide; and a second variety, *Bohea* Pierre (*T. Bohea* L.), which is an unright shrub with dark-green elliptical leaves 6 cm. long and 3 cm. wide. The flowers of the latter occur in groups of two or three, whereas in *viridis* they are single. There are a great many varieties of tea, on the market, and their trade value is influenced by the peculiarities of mother plant and climate, and the degree of ripeness and preparation of the leaves. As a rule only the youngest leaves are gathered. The so-called black and green teas are due to the method of preparation of leaves. In the first the chlorophyll is destroyed, whereas in the latter it is unaffected. Winton gives the following characters as common to all tea leaves: "The firm, rather thick texture; the glossy upper surface; the short stem into which the base of the leaf tapers; the thick margins, rolled a little towards the inner surface, with cartilaginous teeth; the veins which branch from the midrib at angles usually greater than 45 degrees, and at some distance from the margin form loops uniting adjoining ribs. The teeth on the margin of the leaf are shrunken multicellular glands which break off readily from the old leaves." (For discussion of microscopical characteristics, see Winton and Moeller, *The Microscopy of Vegetable Foods.*

The tea plant is a native of China and India, and is cultivated in both countries, but most abundantly in the former. It is also cultivated in India (Assam), Ceylon, Java and in South Carolina. In Japan it forms hedge rows around the rice and corn fields; in China, whence immense quantities of tea are exported, whole fields are devoted to its culture. It is propagated from the seeds.

(An elaborate article on tea, with methods of cultivation, etc., by Wm. B. Marshall, will be found in *A. J. P.*, 1903, p. 79.)

The odor of the tea leaves themselves is very slight, and it is customary to mix with them the flowers of certain aromatic plants, as those of the orange, different species of jasmine, the rose, *Osmanthus fragrans* Lour. (*Olea fragrans* Thunb.), of the *Oleaceæ,* and *Camellia Sasanqua* Thunb., in order to render them pleasant to the smell. The flowers are afterwards separated by sifting or otherwise. (See *P. J.*, xv, 112.) Under the name of *flowers of tea* was at one time sold a waste product consisting of the hair of young leaves, but the flowers themselves have been used to make a beverage. (*P. J.*, lxxi, p. 453.)

Bush Tea and *Honig Thee*, used at Cape Colony, South Africa, as a substitute for tea, are the dried leaves and tops of several species of *Cyclopia,* among which are *C. subternata* Vog., *C. latifolia* DC., *C. genistoides* Vent. (Fam. *Leguminosæ.*) According to the analysis of Henry G. Greenish, they do not contain theine, but a glucosidal body, *cyclopin*, $C_{25}H_{28}O_{13}$. (*P. J.*, xi, 549.)

The numerous commercial varieties of tea may be divided into two great groups, *Green Tea* and *Black Tea.*

The differences between black tea and green tea are due chiefly to the methods of their preparation. In making green tea, the leaves after being dried for a short time in the sun are heated in open pans with continual agitation, somewhat after the manner of roasting coffee. In the case of *black tea* (formerly called *bohea*), the dried leaves are rolled either between the hands or between two flat surfaces, during which process they acquire their characteristic twisted shape and some of the juice is pressed out; they are then piled on mats and allowed to stand exposed to the air at a temperature of 35 to 40° C. for about twelve hours. During this time they undergo a sort of fermentation, which is signified by a change in the color of the leaf from green to red and finally to the dark brown of commerce. It is believed that this change is due to the effect of an oxydase which is called *thease.* As a result of this treatment some of the aromatic principle of the tea leaf is volatilized and a portion of the tannic acid is destroyed. As a rule, therefore, black tea has a somewhat less fragrant odor and a less astringent taste than green tea. Green tea is sometimes artificially colored by means of Prussian blue or other coloring matter.

A sophisticated tea is largely exported from China, consisting of powdered tea mixed with sand and other earth, and agglutinated with gum;

that which is to pass for black being colored with plumbago, and the green with the coating above referred to. On analysis, these teas were found to afford from 35 to 45 per cent. of ash, while the genuine yields only 5 per cent. A very full account of the adulteration of tea and the methods for the detection of the same may be found in Allen, *Com. Org. Anal.*, 2d edition. See also Rehfous, *Pract. Drug.*, Nov., 1917, 38.

The analyses below[1] by Y. Kozai (*Bulletin No. 7, Imperial College of Agriculture,* Japan) have a special value, owing to the author's knowledge of tea manufacture. Unusual precautions were taken in sampling the leaves, to insure strictly parallel specimens being taken. The figures refer to the moisture-free leaves in each case.

[1] Analyses of Tea (percentage composition).	Unprepared Leaves.	Green Tea.	Black Tea.
Caffeine or Theine	3.30	3.20	3.30
Ether Extract	6.49	5.52	5.82
Hot-water Extract	50.97	53.74	47.23
Tannin (as Gallotannic Acid)	12.91	10.64	4.89

The most important principle in tea is the substance discovered by Oudry and by him called *theine,* but which is now known to be identical with *caffeine* (see *Caffeina*). In 1888 Kossel showed the presence of small amounts of a related principle *theophylline* (dimethylxanthin). Traces of theobromine have also been reported. In 1848 Rochleder isolated a yellowish amorphous substance which he called *boheic acid,* but whose chemical identity seems doubtful.

Tea also contains a notable proportion of tannin (from 5 to 20 per cent.) which is very similar to, if not identical with, that of oak bark. There are present also traces of a volatile oil to which is due the characteristic odor. This oil is of a lemon yellow color and easily resinified on exposure to air.

The proportion of caffeine found in tea varies considerably, the general range being from about 1 to 5 per cent.

Tea is astringent and gently excitant, and exerts a decided influence over the nervous system, evinced by the feelings of comfort and even exhilaration which it produces, and the unnatural wakefulness to which it gives rise when taken in unusual quantities or by those unaccustomed to its use. It is almost exclusively used as a beverage. Taken moderately, and by healthy individuals, it may be considered as practically harmless; but long continued in excessive quantity it is capable of inducing unpleasant nervous and dyspeptic symptoms. Green tea is decidedly more injurious in these respects than black, and should be avoided by dyspeptic individuals, and by those whose nervous systems are peculiarly excitable. It is rarely used as a medicine, but the infusion is popularly employed to relieve neuralgic headaches.

Tea Oil. *Tea-seed Oil.*—The seeds of various species of *Camellia,* especially the *C. drupifera* Lour. (*C. oleifera* Wall.) and the *C. Japonica* L., yield on pressure a pale yellow fixed oil which is used by the Chinese both as fuel and food. It has been used in England as an adulterant of olive oil.

The seeds of the *Camellia Japonica,* which sometimes appears in our gardens as an ornamental shrub, are said to contain a poisonous glucoside *camellin.*

Telfairia Pedata Hook. (Fam. *Cucurbitaceæ.*)—The seeds of this East African climbing shrub yield a deep yellow fragrant oil, of specific gravity 0.918, containing *telfairic acid.* (*Chem. Zeit. R.,* xxiv, 24.)

Tellurium. (Te. Atomic weight, 127.5.)—The metal tellurium is a dark gray powder with a specific gravity of 6.25 and melting point of 450° C. The first physiological investigations as to the action of tellurium were made by Hansen (*Chem. Gaz.,* 1854), who found that the *potassium tellurate* was toxic for both dogs and men. His investigations have been extended and confirmed by William J. Gies (*M. A.,* June, 1901), who found that in doses of one-third of a grain per kilogramme sodium tellurate caused in the dog vomiting, diarrhea, unconsciousness, paralysis, convulsions, and death, with pronounced inflammatory changes in the intestines and kidneys similar to those seen after arsenic. Characteristic was the pigmentation of all parts of the body by metallic tellurium. During life the brown or greenish discoloration of urine and the very pronounced garlicky odor of the breath were almost diagnostic. The continuous administration of minute doses had no effect upon metabolism, but if the amount ingested was increased, gastro-intestinal irritation with restlessness soon appeared. Tellurium was found in the feces, urine, breath, and skin secretions. In man drowsiness, nausea and constipation seemed to result from the remedy, given in doses up to half a grain. There was also a marked anhidrotic action, even in healthy men, appearing fifteen minutes to one hour after the ingestion of the dose. Potassium tellurate is an efficient remedy for the arrest of *colliquative sweating,* but the pronounced alliaceous odor which it imparts to the breath, and even to the perspiration, greatly interferes with its use. *Dose* of potassium or sodium tellurate, one-sixth to one-half of a grain (0.01–0.032 Gm.).

Tellurous acid and its potassium salt have been recommended by Gosio (*Zeit. Hyg. u. Inf.,* 1905, li, 65) as an indicator of the presence of living bacteria, especially in sera. He asserts that it is harmless to the human and is reduced by growing bacteria giving rise to color change.

Sodium Tellurite, Na_2TeO_3, is a white powder sparingly soluble in water. The aqueous 2 per cent. solution of sodium tellurite stains bacteria black by the precipitation of *metallic tellurium,* and has been highly recommended for the purpose of microscopic staining. Cavazutti (*Ann. d'Igiene,* 1921, xxxi, 551) finds that sodium tellurite has marked bactericidal properties.

Tephrosia. *Tephrosia virginiana* (L.) Pers. *Turkey Pea. Wild Sweet Pea. Catgut. Goat's Rue. Hoary Pea. Devil's Shoestring. Tephrosie,* Fr., G. (Fam. *Leguminosæ.*)—Several species of *Tephrosia* are employed in different parts of the world, though unknown in general commerce. They are leguminous plants, shrubby or herbaceous, with odd-pinnate leaves and white, red or purplish racemed flowers. They are generally possessed of cathartic properties, their leaves or roots being employed. Plugge (*Proc. A. Ph. A.*, 1897, 560) examined the root of *T. macropoda* and found a poisonous active principle, not identical with cytisine.

Hanriot isolated from *T. vogellii*, a crystalline principle, *tephrosin*, which occurs in small glistening crystals which are almost insoluble in water, slightly soluble in alcohol or glycerin, more readily soluble in acetone, and freely soluble in chloroform. Its formula is $C_{34}H_{26}O_{10}$. *Tephrosal*, $C_{10}H_{16}O$, is a volatile, aromatic liquid, slightly soluble in water, more readily soluble in alcohol, ether, benzin, and chloroform. (*T. G.*, li, 302.)

According to Holmes (*P. J.*, 1910, lxxxiv) this species is used in Africa as a fish poison. Its toxicity seems to be due to the neutral principle, tephrosin. There is no evidence as to its noxiousness for human beings.

Tephrosia virginiana (L.) Pers. is native to dry sandy soil of the Eastern United States. It is a foot or two high, with pubescent stems and leaves and a handsome terminal raceme or panicle of yellowish-white, purple tinged flowers. The roots, which are slender, long, and matted, are tonic and aperient, and are said to have been used by the Indians as a vermifuge, given in the form of decoction.

The leaflets of *T. apollinea* DC. have been employed as an adulterant for Alexandria senna. They may readily be detected by their obovate-oblong outline with emarginate apex and straight, parallel, lateral veins.

Terpinol.—This is not a simple body, but a mixture of terpenes with variable proportions of an alcohol, *terpineol*, $C_{10}H_{17}OH$. It forms a colorless oily substance with a hyacinthine odor; it is produced by boiling terpin with diluted mineral acids. It is insoluble in water, but readily soluble in alcohol and ether. Terpinol has been used in chronic *bronchial catarrh*, and is especially commended by Lazarus when there is much irritation of the membrane with scanty secretion. Janowsky states that it is a valuable remedy in *hemoptysis*. The *dose* is three to five minims (0.2–0.3 cc.) at intervals of from one to four hours, administered in capsules.

Testa Præparata. *Prepared Oyster-shell.*—Powdered oyster shell was at one time used in the same manner as prepared chalk as an antacid in *diarrhea*, in the *dose* of from ten to forty grains (0.65–2.6 Gm.) or more, frequently repeated. A preparation was introduced into use in this country, under the name of *Castillon's powders*, consisting of sago, salep and tragacanth, each, in powder, *a drachm*, prepared oyster-shell, *a scruple*, and sufficient cochineal to give color to the mixture. A drachm of this is boiled in a pint of milk, and the decoction used *ad libitum* as a diet in chronic bowel affections.

Tetrabromphenolphthalein Sodium. *Tetrabromphenolphthaleini Sodium.*—$NaOOC.C_6H_4.C{:}\text{-}C_6H_2Br_2O.C_6H_2Br_2ONa$.—This salt is a purple powder freely soluble in water, forming slightly alkaline solutions. It is precipitated from its solution by acids.

Tetrabromphenolphthalein sodium has been suggested for use in connection with X-ray examination of the gall-bladder. After the intravenous injection of the salt sufficient of it appears in the gall-bladder to cast a shadow on the Roentgen ray plate (see *Phenoltetrachlorphthalein*). The likelihood of toxic effects from the use of large quantities of the drug is, as yet, not accurately established. The doses which have been employed have been equivalent to about 0.1 Gm. per kilo of body weight which means for the ordinary man from seventy to eighty grains (4.5 to 5 Gm.). It is injected intravenously. Smithies and Oleson (*J. A. M. A.*, 1925, lxxxiv, 1494) report two cases of serious irritative phlebitis produced by the sodium salt and prefer the calcium compound.

Graham and Cole (*J. A. M. A.*, 1925, lxxxiv, 1175) have reported on the use of sodium compound of *tetraiodophenolphthalein* for the same purpose. At the present writing the method must be regarded as in the experimental stage, but seems to hold promise as a diagnostic measure of much value.

Tetrachlorethane. *Acetylene tetrachloride.* $CHCl_2.CHCl_2$.—A colorless liquid, sp. gr. 1.582, boiling point 147° C. Soluble in alcohol and ether, insoluble in water. A solvent for greases and waxes, and also used in cellulose acetate varnishes. A number of cases of poisoning from the use of this compound in industries have been reported. According to Lehmann (*Arch. f. Hyg.*, 1911, lxxiv) it is many times more toxic than either chloroform or carbon tetrachloride. The symptoms observed in industrial poisoning by it have been drowsiness, nausea, destruction of blood corpuscles, jaundice and in fatal cases symptoms resembling those of acute yellow atrophy of the liver. For further information upon this subject see Hamilton (*J. A. M. A.*, 1917, lxix, 2037) and Minot and Smith (*A. I. M.*, 1921, xxviii, 687).

Tetragastris. *Tetragastris panamensis* (Engl.) O. Kuntze. *Bois Cochon*, or *Sucrier de Montagne*, Fr. (Fam. *Burseraceæ.*)—This native of Panama has been examined by Gaucher, Combemale and Marestang (*France Méd.*, October, 1888), who find in it an alkaloid and a resin. The extract of the root and stems produce in the guinea pig rapid and considerable lowering of temperature, progressive paralysis, general convulsions, dilatation of the pupils, respiratory irregularity and cardiac paresis. The alkaloid was found to be a convulsive agent, acting upon the spinal cord. The resin, which seemed much more active than the alkaloid, acted as a paralyzant.

Tetralin.—A name applied to solvents made from *tetrahydronaphthalene*—$C_2(CH_2)_4(CH)_4$—and *dekahydronaphthalene* made by the hydrogenation of naphthalene. They are used in varnishes and shoe polishes. It is used in the preparation of a diagnostic test for tuberculosis devised by Wassermann (*D. M. W.*, 1923, xlix, 303).

Tetronal. *Diethyl-sulphone-diethyl-methane.* $(C_2H_5)_2C(C_2H_5SO_2)_2$.—This occurs as a white crystalline powder, insoluble in water, soluble in alcohol and fusing at 85° C. The effects of this compound are practically the same as the closely allied *Trional.* (See Part I.) Although the introducers of this group of drugs, Baumann and Kast (*A. E. P. P.*, 1892, xxxi), classed tetronal as the most powerful of the group, it has failed to achieve the popularity of the official representatives. The *dose* is from eight to fifteen grains (0.5–1 Gm.).

Teucrium. *Teucrium Chamædrys* L. *Germander Chamædrys. Petit Chêne*, Fr. *Edlar, Gamanderlein, Frauenbiss*, G. (Fam. *Labiatæ.*)—A perennial herb indigenous to Europe which possesses ovate to oblong, incised, crenate leaves and axillary whorls together with terminal racemes of showy reddish-purple or rose colored flowers, with red and white spots on the corolla. It has been employed as a mild corroborant in *uterine, rheumatic, gouty* and *scrofulous affections* and *intermittent fevers.* Germander was an ingredient in the *Portland powder,* noted as a remedy in gout. This powder, according to the original prescription, consisted of equal parts of the roots of *Aristolochia rotunda* L. and *Gentiana lutea* L., of the tops and leaves of *Teucrium Chamædrys* and *Erythræa Centaurium* (L.) Pers. and of the leaves of *Ajuga Chamæpitys* Schreb., or *ground pine.* The *dose* was a drachm every morning before breakfast for three months, then forty grains for three months, afterwards half a drachm for six months, and finally half a drachm every other day for a year. (Parr.)

Two other species of *Teucrium* have been used in medicine,—*T. Marum* L., *cat thyme,* or *Syrian herb mastich,* indigenous in the south of Europe, and *T. Scordium* L., or *water germander,* growing in the higher latitudes of the same continent. The former is a warm, stimulating, aromatic bitter, and has been recommended in *hysteria, amenorrhea* and *nervous debility;* the latter has the odor of garlic and a bitter, somewhat pungent taste, and was formerly highly esteemed as a corroborant in *low forms of disease;* but neither of them is now much employed. *T. Marum* is an errhine, and was formerly an ingredient of the *Pulvis Asari Compositus.*

A plant said to have been used advantageously in *cholera* in the Levant, a specimen of which was sent to Paris, proved to be *Teucrium Polium* L. (*J. P. C.*, xv, 352.) Moorhof (*Ph. Cent.*, 1893, 89) prepared a purified liquid extract from *T. Scordium,* and named it *teucrin,* which he recommends in the treatment of fungoid diseases and abscesses.

The *dose* of either of the three species is about half a drachm (2.0 Gm.).

Tfol is an argillaceous earth, containing free gelatinous silica, which is largely used in northern Africa as a substitute for soap. It has been strongly recommended by Lahache for the purpose of emulsifying tar oil and for disinfecting purposes.

Thalictrum.—This is a genus of perennial herbs belonging to the *Ranunculaceæ* and characterized by possessing alternate, ternately-compound or decompound leaves and small flowers, with petaloid or greenish calyx and no corolla, arranged in panicles or corymbs. It appears probable that many species of this genus have active medicinal or toxic properties. In 1879 Henriot and Doassans asserted that they had separated from the roots of the *Thalictrum macrocarpum* Gren., a shrub of the Pyrenees, a crystalline yellow subtance having very pronounced toxic principles, analogous to those of curare; and subsequently stated (*C. R. S. B.*, 1880) that this substance really consists of two principles,—an alkaloid, *thalictrine,* obtained in the form of prismatic needles, insoluble in water, soluble in alcohol, forming crystalline salts with acids, and *macrocarpin,* a yellow crystalline body, soluble in water, representing the coloring principle of thalictrum. Subsequently *berberine* was found by Doassans and Mousset in *Thalictrum flavum* L., *Fen Rue* or *Monk's Rhubarb,* a shrub widely distributed in Europe and Asia, macrocarpin being, according to this authority, very closely allied to berberine, but differing in that its color is not affected by ammonia. Rochebrune (*Toxicolog. Africaine,* i) has found both thalictrine and macrocarpin in the roots of *Thalictrum glaucum* Desf., of Spain. Thalictrine he states to be a very active cardiac poison, producing loss of power, convulsive movements, irregularity and depression of the heart's beat, and finally death, in some cases with convulsions. According to Rochebrune, thalictrine also exists in the African species *Thalictrum rhynchocarpum* Q. Dillon and A. Rich.

Thalline. *Tetrahydroparaquinanisol* or *Tetrahydroparamethyloxyquinoline.* $C_9H_6H_4N(OCH_3)$.—The term *anisol* is applied to the methyl ether of phenol, and it is therefore methyloxybenzene. Skraup's synthesis of quinoline, C_9H_7N, was effected by heating aniline or amidobenzene with nitrobenzene, glycerin and sulphuric acid. By taking instead paramidoanisol, paranitroanisol, glycerin and sulphuric acid, Skraup obtained paraquinanisol, $C_9H_6N(OCH_3)$. This is then treated with tin and hydrochloric acid, when it takes up four atoms of hydrogen and becomes $C_9H_6H_4N(OCH_3)$. The name *thalline* was given to this base because of the deep green color produced by ferric chloride and other oxidizing agents. The base thalline is obtained in well-formed rhombic crystals, which fuse at 40° C. and recrystallize on cooling. It shows a neutral reaction and has a characteristic aromatic odor resembling that of coumarin. It is soluble in water, alcohol, and ether.

Thalline sulphate is a white crystalline powder which loses its two molecules of water of crystallization at 100° C. and melts at 110° C. It is soluble in five times its weight of cold water and freely soluble in boiling water, soluble in 100 parts of alcohol. Both solutions turn brownish on exposure to air and light. The odor of the sulphate recalls that of anisol. *Thalline tartrate* is a white crystalline powder, fusing at 155° C. and possessing a coumarin-like odor. It is soluble in ten parts of water and hardly soluble in alcohol. Its aqueous solution has an acid reaction.

Thalline tartrate and sulphate are medicinally equivalent. They are powerful antipyretics, acting also, when in sufficient dose, as depressants both upon the vasomotor system and upon the heart, and, according to A. Robin, checking tissue waste in the body and having a very marked tendency to attack the red blood corpuscles. These salts have been used in practical medicine, in *doses* of from four to eight grains (0.26–0.5 Gm.), but are so prone to produce disagreeable symptoms, such as marked cyanosis, vomiting, diarrhea, albuminuria, etc., that their employment has been abandoned. According to Kreis, in from 4 to 4½ per cent. solution they are active germicides, and the frequent use of urethral injections of the 1 to 2 per cent. solution has been found very useful in *chronic gonorrhea.* Moncorvo states that thalline is an active hemostatic.

Thalline Periodide. *Thalline Periodosulphate.*—An iodine addition product of thalline sulphate. It occurs as black crystals soluble in alcohol. It has been used in the treatment of *carcinoma,* three to four grains (0.2–0.25 Gm.) being given in pill form every two or three hours. In cases where functional activity of the epidermal glands has ceased, pilocarpine in slight doses is given at the same time.

Thalline Salicylate. $C_{10}H_{13}NO.C_7H_6O_3$.—This occurs as a reddish, crystalline powder, soluble in alcohol and administered as an antiseptic and antipyretic in the treatment of gonorrhea, typhoid fever, etc. *Dose,* three to eight grains (0.2–0.5 Gm.).

Thallium. (Tl. Atomic weight, 204.0.)—A bluish white lead-like metal. Sp. gr. 11.85, melting point 302° C. Insoluble in water, dissolved by nitric and sulphuric acids. This metal, discovered by spectrum analysis, has been found to occur widely in nature.

Thallium is an active poison, according to Swain and Bateman (*J. Bi. Chem.*, Jan., 1910), only slightly less toxic than arsenic. Moreover, it is distinctly accumulative in its effects, so that small doses repeated over periods of time may produce serious intoxication. The symptoms of acute poisoning in the lower animals by thallium are a disordered muscular action, as shown by tremors, incoördination, gradually increasing paralysis. Often, also, there is evidence of irritation of the intestinal tract, with vomiting and diarrhea. The pupils are dilated, there is salivation, conjunctivitis, with free mucous secretion, diuresis, embarrassment of respiration and more or less weakness of circulation. Death occurs in coma and is due to respiratory failure. After death there may be found some effusion of blood and inflammation of the lungs and intense congestion of the bowels, pericardial effusion and ecchymosis of the heart surface.

Cases of poisoning are uncommon in man, but Ballard (*Reports of the Boston City Hospital,* 1902) has recorded a case in which, after between two to four grains which were taken in the course of a week, there were produced diarrhea, muscular weakness and tenderness over the nerve trunks. As both lead and arsenic were found in the urine, however, it was doubtful how far the symptoms were due to the thallium. Olmer and Tian (*C. R. S. B.*, lxv, p. 742) report a case in which, after application of a paste of acetate of thallium to the chest, there were pains in the extremities, stomatitis, albuminuria and widespread alopecia. The loss of hair has been an almost constant symptom of human poisoning, and also occurs, according to Swain and Bateman, in the lower animals. (See also Buschke and Peiser, *B. K. W.*, 1922, i, 995.)

Sabouraud (*Revue Internationale de Medecin,* 1912) has recommended an ointment containing 1 per cent. of thallium acetate as a depilatory.

That thallium can produce widespread general neuritis is strongly indicated by the violent pains, especially of the legs, which have been noted by Lamy, by Combemale, and other observers, and also by the muscular atrophy which appears to be pronounced in chronic poisoning by the drug in the lower animals. Curci, indeed, claims that thallium is exclusively a muscle poison, and as long ago as 1874 Rabuteau recorded that after death from thallium the muscles did not respond to irritation. (See *Ed. M. J.*, 1874.) Pozzi and Courtade assert that in some cases thallium causes swelling of the gums with a blue line at the junction with the teeth, but this symptom seems not to have been noticed by other observers.

In 1898 Combemale claimed that in *doses* of one and a half grains (0.096 Gm.), given at bedtime, *thallium acetate* is a valuable remedy in the *colliquative sweats* of phthisis; that it is effective has been proved by Huchard and others; but in many cases it has produced severe peripheral pains, loss of hair, abdominal disturbance, and other disagreeable symptoms.

Thapsia. *T. Garganica* L. *Thapsie, Faux Fenouil,* Fr.—An umbelliferous plant, growing in southeastern Europe, and well known to the ancients, named from the isle of Thapsos, where it was obtained. Theophrastus speaks of its root as emetic and purgative. After long neglect this plant has obtained a foothold in the French Codex, which recognizes a *Resina Thapsiæ* prepared by exhausting the bark of the root with alcohol and evaporating to a soft extract. From this extract the Codex further directs that an *Emplastrum Thapsiæ* shall be so prepared as to contain 7 per cent. of the resin combined with yellow wax, turpentine and colophony. The bark of the root and the resin are both objects of commerce. The bark is described by Stanislaus Martin as almost always doubly quilled, unless where altogether in small fragments, exteriorly rugose with the epidermis here and there detached in patches larger or smaller, and of a deep brown color, interiorly smooth and whitish and of a fibrous fracture. The size of the pieces varies, the largest not exceeding 6 dm. in length and 2.5 in width. It is said that great care is necessary, in removing the root from the bales, not to be injured by the powder which escapes, and which causes itching and swelling of the face and hands. By submitting *thapsia* to the successive action of alcohol and ether Pressoir obtained two resins. (*J. P. C.*, 4e sér., xi, 328.) Canzoneri finds that the ethereal extract is an amber-colored syrupy resin possessing vesicating properties. From it he has obtained two acids, *octoic* or *caprylic* acid, and *thapsic* acid, besides a neutral non-nitrogenous vesicating substance. (See *A. J. P.*, vol. xiv, 325.) The French thapsia plaster is an active counter-irritant, producing much inflammation of the skin with an eczematous eruption and intolerable itching and, if the application be maintained, finally an ulcerated and suppurated surface, which on healing leaves behind it pronounced scars. The therapeutic action of the plaster is that of a severe counter-irritant.

The resin from the root of *Thapsia Sylphium* St. Laz., an Algerian plant, which most botanists believe to be a simple variety of *T. Garganica* L., is, according to Herlaut, even more active than the official plant. (*Proc. A. Ph. A.*, xxvi, 250.) Heckel and Schlagdenhauffen (*N. R.*, June and July, 1887) find in the root of *Thapsia villosa* L. a vesicant resin, which acts more slowly and gently than does that of *T. Garganica.*

Theobromine Preparations.—The alkaloid *theobromine* (see Part I), which is itself insoluble in water, unites with several of the earthy metals to form soluble compounds. Advantage of this fact has been taken by manufacturers to place upon the market a large number of soluble preparations of theobromine. The majority of these preparations have the same range of therapeutic usefulness as the official theobromine and sodium salicylate.

Theobromine Acetyl-salicylate. Theocyl. $C_7H_8O_2N_4.C_9H_8O_4$.—A white crystalline powder, soluble in alcohol and insoluble in water. It has been stated that this combination has the advantage over other theobromine preparations of not being irritant to the stomach. *Dose,* five to fifteen grains (0.33–1.0 Gm.).

Theobromine Barium and Sodium Salicylate. Barutin.—This is a white, amorphous powder with a sweetish alkaline taste and soluble in about twenty parts of water. It represents about 25 per cent. of theobromine and 17 per cent. of barium. Carbonic acid causes a precipitation.

The *dose* assigned to it is from three to eight grains (0.2–0.5 Gm.), which should be given well diluted but it would seem that this amount would represent a rather large quantity of barium.

Theobromine Lithium. Theobromose. $C_7H_7O_2N_4Li$.—It occurs as fine needle-like crystals, which are soluble in about one-half their weight of water. The solution is readily decomposed by atmospheric carbonic acid. It is used as a diuretic.

Theobromine and Lithium Benzoate. Uropherin B. $LiC_7H_7O_2N_4 + LiC_7H_5O_2$.—A white powder, soluble in five parts of water, representing 47 per cent. of theobromine. Precipitated by carbonic acid. It is stated to be more actively diuretic than other salts of theobromine. *Dose,* five to fifteen grains (0.3–1 Gm.).

Theobromine and Lithium Salicylate. Uropherin S. $LiC_7H_7O_2N_4 + LiC_7H_5O_3$.—Properties and uses the same as those of *Uropherin B.* but it is somewhat more prone to disturb the stomach.

Theobromine and Sodium Acetate. N. N. R. 1924. *Agurin. Theonacet.* $C_7H_7O_2N_4Na + NaC_2H_3O_2$.—A white, hygroscopic, alkaline powder, representing 60 per cent. of theobromine, readily soluble in water, forming a strongly alkaline solution which is incompatible with most inorganic salts, causes precipitation of alkaloids from solutions of their salt, darkens calomel, reduces potassium permanganate solution and is precipitated by carbon dioxide. The dry substance becomes pasty when triturated with chloral hydrate, phenol or piperazin. It is incompatible with carbonated beverages, acids, saccharin and mucilaginous liquids, alkaloids and alkaloidal reagents generally. Used as a diuretic. *Dose,* five to fifteen grains (0.3–1 Gm.) in solution.

Theobromine Salicylate. $C_7H_8O_2N_4.C_7H_6O_3$.—This forms fine white needle-like crystals of a bitter taste, acid in reaction and fairly soluble in water. *Dose,* five to fifteen grains (0.3–1 Gm.).

Theobromine and Sodium Benzoate.—A white soluble powder, representing 47 per cent. of theobromine. *Dose,* eight to fifteen grains (0.5–1.0 Gm.).

Theobromine and Sodium Citrate. Urocitral.—A white, alkaline powder, moderately soluble in water, representing 45 per cent of theobromine. *Dose,* eight to fifteen grains (0.5–1.0 Gm.) several times a day.

Theobromine Sodium Formate. Thephorin. $NaC_7H_7O_2N_4 + NaCHO_2 + H_2O$.—A white, alkaline, bitterish powder, soluble in 10 parts of water and representing 62.5 per cent. of theobromine. Used as a diuretic. It is asserted to be more irritant to the kidneys than other theobromine salts, and must be used with caution in *nephritis. Dose,* five to eight grains (0.3–0.5 Gm.).

Theobromine and Sodium Iodide. Sodium Iodotheobromate. Eustenin. $C_7H_7O_2N_4Na.NaI$.—This is a white, hygroscopic powder, freely soluble in water, but decomposed with precipitation by carbonic and other acids. It represents 51 per cent. of theobromine and 42.6 per cent. of sodium iodide. It is believed to combine the therapeutic effects of these two drugs and is recommended especially as an antisclerotic in arterial degenerations, *angina pectoris, chronic nephritis* and similar conditions. The *dose* is eight to fifteen grains (0.5–1.0 Gm.) several times a day.

Theobromine and Sodium Lactate.—A white hygroscopic alkaline powder, soluble in sixteen parts of water, readily decomposed by atmospheric carbonic acid.

Theobromine and Sodium Sulphate.—A white powder, soluble in water and containing about 50 per cent. theobromine. It is used like other theobromine salts.

Theobryl. Allyl Theobromine.—Koch and Katzenelbogen (*Schweitz. Med. Woch.*, 1921, li, 1009) find that this preparation has the advantages over other theobromine compounds of free solubility with neutral reaction which makes it suitable not only for oral but for subcutaneous administration. They also assert that it is more actively diuretic. They used it in *doses* of 0.3 to 0.5 Gm. (5 to 8 grains) daily.

Theophylline Compounds.—Although theophylline is now official, it is more frequently employed in the form of one of its soluble compounds. The following are upon the market:

Theophylline Ethylene Diamine. Euphyllin.—This is a white crystalline substance, freely soluble in water and representing 78 per cent. of theophylline. The *dose* recommended is from one and a half to three grains (0.1–0.2 Gm.).

Theophylline Sodium Acetate. Acet-theocin Sodium. N. N. R. 1924. $NaC_7H_7O_2N_4 + NaC_2H_3O_2 + H_2O$.—This is a white, crystalline powder, representing approximately 60 per cent. of theocin, soluble in twenty parts of water. It is used as a diuretic in *doses* of three to five grains (0.2–0.3 Gm.) several times a day.

Theophylline Sodium Salicylate. $C_7H_7O_2N_4Na.C_6H_4.OH.COONa$.—This is soluble in fourteen parts of water. Its doses and uses are the same as the preceding.

Theophylline Sodium Formate. $C_7H_7O_2N_4Na.HCOONa + H_2O$.—This occurs as a white powder, soluble in water and possessing valuable diuretic properties. *Dose,* eight to fifteen grains (0.5–1 Gm.).

Thermin. *Tetrahydro-β-naphthylamine Hydrochloride.* $C_{10}H_7.H_4.NH_2.HCl$.—The tetrahydro addition compound is formed when metallic sodium is caused to act upon naphthylamine in boiling amyl alcohol solution. It is a colorless to reddish-white crystalline powder, soluble in water, alcohol and amylic alcohol. The hydrochloride has been brought forward by Filehne of Breslau, as a local mydriatic of extraordinary power.

Jonescu (*A. E. P. P.*, 1909, lx, p. 345) has shown that tetra-hydronaphthylamin causes dilatation of the pupil by stimulating the sympathetic nerves and that the dilatation follows either the local installation or the subcutaneous injection of the drug; that it causes marked constriction of the blood vessels, chiefly by acting upon the vasomotor centers, although he believes the peripheral nerves to the vessels are also affected. The rise in temperature which it causes he attributes to a direct action upon the heat centers. According to Feri (*A. I. P. T.*, 1911, xxi, p. 27) there is, in poisoning by thermin, an increase in heat production with lessened heat dissipation which differentiates at once the fever it produces from that seen, for example, in infectious diseases. According to Sacharoff (*Z. E. P. T.*, vii, p. 225) the spasm of the blood vessels of the skin is in part responsible for this rise of temperature by preventing the dissipation of the excessive caloric. Thermin appears to cause a non-maximum dilation of the pupil and does not destroy the light reflexes. It is used as a mydriatic in strengths of from 1 to 5 per cent.

Thermodin. *Acetyl Para-ethoxy-phenyl-urethane.* $C_6H_4(OC_2H_5)N(COCH_3)COOC_2H_5$.—A derivative of urethane in the form of a colorless, crystalline powder, fusing at from 86° to 88° C., insoluble in water. It is used as an antipyretic in *doses* of from five to fifteen grains (0.32–1.0 Gm.).

Thermol. *Acetyl-salicyl-phenetidin. A-s-phen.* $C_{17}H_{17}NO_4$.—This substance is a white, crystalline, odorless, tasteless powder, which is claimed to be a harmless and active antipyretic and analgesic and as such has been used to a considerable extent in *typhoid fever, neuralgia, dysmenorrhea, migraine,* etc.; also as an antispasmodic in *whooping cough. Dose,* three to fifteen grains (0.2–1.0 Gm.).

Thevetia. *Yccotli.*—Inhabiting the damp, hot valleys of the Mexican Cordilleras is a large tree belonging to the *Apocynaceæ,* whose fruits are known by the natives as *huesos ó codos de fraile,* or *friar's elbow bones,* and are used as a topical application in *hemorrhoids.* The tree is the *Thevetia Yccotli* A. DC. In the seeds Herrera found a *glucoside, thevetin.* (*A. J. P.,* 1877, 145.) Closely allied to *T. Yccotli* is *T. nereifolia* Juss., a tree which probably grows also in Mexico, but has been found by botanists chiefly, if not solely, in the West Indian Islands, Colombia, Peru and other parts of South America. De Vrij, many years ago, discovered in its seeds a glucoside, *thevetin,* which was at one time believed to be identical with *cerberin* previously discovered in *Cerbera Odallam,* but Plugge (*A. Pharm.,* 1893, 10) reached the conclusion that they were distinct compounds. Under the name, however, of *cerberin* or *cerberid* Merck's index lists the "glucoside from the fruit of the *Thevetia yccotli,*" to which is assigned the formula $C_{25}H_{38}O_{12}$. Herrera (*M. R.,* 1911) found in thevetia a crystalline glucoside, *thevetosin,* which is a cardiac poison. Cerberin, $C_{27}H_{40}O_8$, is decomposed into *cerberetin,* $C_{19}H_{26}O_4$, a citron-yellow amorphous powder melting at 85.5° C., and glucose, while thevetin, $C_{54}H_{84}O_{24}$, is split into *theveresin,* $C_{48}H_{70}O_{17}$, a white powder, and glucose.

A number of cases of poisoning by the seeds of the East Indian thevetia has occurred; the symptoms have been repeated vomiting, a slow, very feeble pulse, delirium, convulsive movements and coma. The physiological action of the thevetin from *T. nereifolia* has been investigated chiefly by König. (*A. E. P. P.,* Bd. v, 228.)

David Cerna finds that the glucoside of *T. Yccotli* (*P. M. T.,* ix, 396) is in moderate doses stimulant both to the circulation and respiration, but finally paralyzes the heart muscle and the respiratory apparatus; that it causes cerebral convulsions and spinal paralysis, abolishing sensation and reflex activity before voluntary movement by an influence upon the sensory nerves or spinal tract. Zotos N. Zotos (*In. Dis.,* Dorpat, 1892) states that *cerberin* belongs physiologically to the digitalin group.

Thiocol. *N. N. R.* 1924. *Potassium Guaiacol Sulphonate. Orthocoll.* $C_6H_3.(OCH_3)OH.SO_3K$.—This is a fine white powder, having a taste at first bitter and afterwards sweetish; readily soluble in water, sparingly so in alcohol; containing about 60 per cent. of guaiacol. It is pleasant to the taste and not irritant to the gastric or other mucous membranes. Its freedom from odor, ready absorption and non-irritant action on the mucous membrane are among its recommendations that have been reported by its introducers. The original commendation of it by C. Schwartz (*K. T. W.,* 1898), in *tuberculosis, chronic bronchitis* and *intestinal catarrh,* has been confirmed by various clinicians. Cole (*Practitioner,* November, 1911) finds its effects about the same as those of creosote, over which it has the great advantage of being practically tasteless and much less likely to irritate the stomach. It occasionally produces a rash which, however, disappears quickly when the remedy is stopped. The *dose* is eight to twenty grains (0.5–1.2 Gm.).

Thionine. *Lauth's Violet.*—The oxidation product of *imidamidoiodiphenylimide,* $C_{12}H_{10}N_3SCl$. A greenish-black powder, having a metallic luster. It dissolves easily in water, imparting to the solution an intense violet color. It is used as a microscopic stain for nuclei and also in metachromatic investigations (for mast cells, mucus, etc.).

Thiophene (C_4H_4S) was recognized by Victor Meyer in 1883 as being an invariable accompaniment of benzene as produced from coal tar, and because of the similarity of properties, adhering very closely to it through all reactions. It can be separated by shaking the benzene with one-tenth of its bulk of concentrated sulphuric acid until the addition of a little isatine no longer produces a blue color (indophenin reaction). Steinkopf obtained a 40 per cent. yield of *thiophene* by passing acetylene over pyrites heated to 300° C. (*Chem. Trade Jour.,* 1911, 394.) Thiophene is a colorless, mobile oil, of faint odor, and boils at 84° C. Just as benzene is accompanied in coal tar by toluene, xylene and higher homologues, so thiophene is accompanied by *thiotolene* (*methyl-thiophene*), $C_4H_3S.CH_3$, and *thioxene* (*dimethyl-thiophene*), $C_4H_2S.(CH_3)_2$. Thiophene and its homologues yield a large number of brilliant dye colors analogous to those derived from benzene. It was first physiologically tested by A. Heffter (*A. G. P.,* xxxix, 420), who found that it appeared in the urine, and lessened the elimination of sulphuric acid in the urine. E. Spiegler (*Th. M.,* Feb., 1892) has employed in *skin diseases*—1, *Sodium thiophene sulphonate,* $C_4H_3S—NaSO_3$; 2, *Thiophenediiodide,* $C_4H_2I_2S$. The first of these compounds is a white crystalline powder, containing 33 per cent. of sulphur, having a feeble, disagreeable odor. It was found in the form of an ointment to act very well in *prurigo* with *eczema.* Thiophenediiodide occurs in tabular crystals, melting at 40.5° C., having a characteristic, not disagreeable odor, insoluble in water, but very feebly soluble in ether, chloroform and warm alcohol, soluble with difficulty in cold alcohol; containing 75.5 per cent. of iodine and 9.5 per cent. of sulphur. It was found to be antiseptic and is one of the compounds suggested as a substitute for iodoform. The *tetrabromide of thiophene,* C_4Br_4S, obtained by the complete bromination of theophene, is recommended as an antiseptic. It occurs as a yellow crystalline powder soluble in alcohol.

Thioresorcin. $C_6H_4(OS)_2$.—A yellowish-gray powder, insoluble in water, made by fusing together one molecule of resorcinol and two molecules of sulphur. It has been recommended as a substitute for iodoform, but has given rise to unpleasant symptoms.

Thiosinamine. *Rhodallin. Allylthio-urea. Allylsulpho-urea. Allylsulphocarbamide.* $(NH_2).CS.NHCH_2.CH : CH_2$.—This occurs in colorless, monoclinic or rhombic crystals, of a bitter taste and feeble garlic-like odor. It is moderately soluble in water, very soluble in alcohol and ether. It possesses no bactericidal properties.

Under the name of *Fibrolysin* a 15 per cent. solution of the double salt of *thiosinamine* and *sodium salicylate* is marketed in the form of ampules, containing 2.3 cc. of the solution. This solution decomposes rapidly on exposure to the air.

Thiosinamine was introduced into medicine by Von Hebra (*Internat. Klin. Rundschau*, September, 1905) in the treatment of various conditions accompanied with formation of fibrous tissue. He states that after its injection there is a temporary reduction in the number of leukocytes, followed by pronounced hyper-leukocytosis which persists for a considerable period of time. The occurrence of leukocytosis has been pretty generally confirmed by a number of authorities, some of whom have attributed the beneficial effects of the drug to this action. Starkenstein, however (*Th. M.*, 1910), believes that it is due to a power of encouraging the hydrolysis of collagen into gelatin, thereby leading to the softening of the connective tissue. While there is some contradiction of opinion among those who have investigated the action of this drug clinically, there is considerable evidence that it is often a remedy of great service in aiding in the absorption of connective tissue. Among the conditions in which this remedy has received recommendation may be mentioned excessive scarring as from *burns, keloids, urethral* and *œsophageal strictures*, and various other forms of cicatricial formations. Besides these, asserted benefit has been reported in sclerotic conditions of the ear attended with *deafness*, and in sclerosis of the central nervous system as *locomotor ataxia*, and in *arterial fibrosis*. It has also been suggested by Greenbaum (*J. A. M. A.*, 1911, lvi, 835) as a protective against dermatitis after arsphenamine injections.

The remedy, whatever may be said of its efficacy, is not entirely innocuous. A number of instances of excessive reaction, attended with chills and sweating followed by fever, have been reported, and Pritchard reports a case of *purpura hemorrhagica*, which ended fatally, following 18 injections. Tyrode (*A. I. P.*, 1910, xix, 195) has found that relatively small doses may produce in the lower animals severe disturbances of metabolism with degeneration of the internal organs.

Thiosinamine may be administered by the mouth in *doses* of one-half to two grains (0.03–0.12 Gm.) several times a day; for hypodermic use it may be dissolved in alcohol or glycerin. Fibrolysin is marketed only in the form of hermetically sealed vials each of which represents five grains (0.2 Gm.) of thiosinamine. The contents of one of these vials may be injected at one *dose* daily, or on alternate days.

Iodolysin is a compound said to contain 43 per cent. of thiosinamine and 47 per cent. of iodine. The advantage is claimed over other preparations that it is non-irritant and is especially suitable for hypodermic injection. Whitehorn-Cole (*F. Th.*, 1910, p. 69) reports favorably upon its use in *rheumatic arthritis*. The *dose* is from five to eight grains (0.32–0.5 Gm.).

Thiosinamine-ethyl-iodide. *Tiodine.* $C_6H_{13}N_2SI$.—Under the name of *tiodine*, the compound resulting from heating thiosinamine with ethyl-iodide has been introduced into medicine. Its formula is

$$C \begin{cases} \diagup NH_2.C_2H_5I \\ = S \\ \diagdown NH—C_3H_5. \end{cases}$$

It forms colorless crystals readily soluble in water and alcohol. It has been used for the same class of cases as thiosinamine, especially, however, for the relief of lesions of the central nervous system. Its injection is stated to be painless. It may be administered either by mouth or hypodermically. The *dose* is from one and one-half to three grains (0.1–0.2 Gm.), if by the mouth several times a day, if hypodermically, every other day.

Thistle.—Several of the *Compositæ* which are popularly called "thistles" have been attributed with therapeutic properties. The following merit attention.

Cirsium arvense (L.) Scop. (*Cnicus arvensis*, Hoffm.) *Canada Thistle.*—This is a European plant, but widely naturalized in this country. To it have been attributed diaphoretic, emetic, and tonic properties, according to Herman J. Pierce (*A. J. P.*, lxviii, 1896), contains a volatile alkaloid, and also *cnicin*, $C_{42}H_{56}O_{15}$. This is crystallizable, inodorous, very bitter, neutral, scarcely soluble in cold water, more soluble in boiling water, and soluble in all proportions in alcohol. It is analogous to salicin in composition. It is said to possess emetic and emmenagogue properties.

Cnicus benedictus L. (*Centaurea benedicta* L.) *Blessed Thistle. Chardon bénit*, Fr. *Herba Cardui Benedicti*, P. G. *Benedicten Distel*, G. (Fam. *Compositæ.*)—This is an annual herb, common in Europe and occasionally seen on roadsides and waste places in the United States. The leaves were formerly official. They should be gathered when the plant is in flower, quickly dried, and kept in a dry place. The herb has a feeble, unpleasant odor and an intensely bitter taste, more disagreeable in the fresh then in the dried plant.

Water and alcohol extract its virtues. The infusion with cold water is a grateful bitter; the decoction is nauseous, and offensive to the stomach. The active constituents are volatile oil and *cnicin*. It has been used as a bitter tonic, and is, in larger quantities, emetic. Tonic *dose*, from half a drachm to one drachm (2.0–3.9 Gm.) preferably given as an infusion.

Silybum Marianum (L.) Gaertn. (*Mariana Mariana* (L.) Hill, *Carduus Marianus* L.) (*Milk Thistle. Lady's Thistle* (Fam. *Compositæ*) was of old used for the same purpose as *C. benedictus*. Rademacher attributed great value to the seeds in *hemorrhages*, particularly when connected with diseased liver or spleen. A decoction (two ounces to the pint of water), in *doses* of four fluidrachms (15 cc.) every hour, has been used in *amenorrhea* and *menorrhagia*.

Thorium. Th. 232.15.—A gray, heavy, infusible powder. Sp. gr. 11.00, melting point over 1700° C. Soluble in acids. Insoluble in alkalies. One of the radium group of metals which is coming into prominence in medicine through the uses of its salts. The illuminating power of gas mantles is closely dependent upon a particular proportion of thorium oxide in the composition. *Thorium dioxide* has been used as a substitute for bismuth subnitrate in making X-ray pictures of the alimentary tract. According to Kaestle (*M. M. W.*, 1908), it is absolutely inert physiologically, and is very opaque to the X-ray. J. E Burns of Johns Hopkins Hospital recommends for X-ray examination of the ureter and kidney, the soluble *Thorium-sodium citrate* (*N. N. R.* 1924). This is prepared as follows: To prepare it, 10 Gm. of thorium nitrate dissolved in distilled water and heated on the water bath are treated with 30 cc. of a 1:2 solution of sodium citrate, added slowly with constant agitation. The precipitate at first formed is redissolved in the excess of the alkali citrate solution. The liquid is then exactly neutralized with normal sodium hydroxide solution and the volume is made up to 100 cc., when cold, with more water. After filtration, the clear filtrate, sterilized by boiling, is ready for use. That it is quite non-irritant is shown by subsequent cystoscopic examination. The solution is introduced by gravitation, as by the use of the syringe overdistension of the renal pelvis may result. The toxic dose for man, intravenously, would allow more than ten times the quantity required for a pyelogram to be used, or some hundreds of times more than could be absorbed during the procedure. S. Tracey has used the antiseptic action of a current of air passed over heated thorium oxide in the treatment of *tuberculosis* with apparently beneficial results.

Thorium Nitrate. *N. N. R.* 1924. $Th(NO_3)_4 + 4H_2O$.—It forms white, aggregate crystals which are very soluble in water. Depending on the fact, or the belief, that thorium salts are radio-active much attention has been called to this salt as being the most advantageous of the thorium salts for utilization. A solution of the nitrate has been employed in the treatment of parasitic skin diseases and a weak solution has been administered internally in the treatment of *rheumatism.*

Thromboplastin. *N. N. R.* 1924.—The normal coagulation of the blood which occurs after external wounds, according to present theories, is due to the change of a substance *fibrinogen,* normally found in the blood, into fibrin. This change is brought about by union with a substance known as *thrombin,* the elements of which—*prothrombin* and *calcium*—are normally found in the blood but which are prevented from uniting by the presence of a substance called *antithrombin.* The disintegration of tissue cells liberates a substance that neutralizes this antithrombin and thus permits a clotting of the blood. To this material, which is obtained from disintegrating tissue cells of various kinds, a variety of names has been applied as *thrombokinase, zymoplastic* and *thromboplastic* substances, *cytocym,* etc. It corresponds in its physical properties to the lipoid substance found in the brain called *kephalin.* (Howell, *A. J. Phys.,* 1912, xxxi, 1.)

It is probable that most of the animal substances which have been used for the purpose of increasing the coagulability of the blood act by furnishing this thromboplastic substance. It has been known for many years that the hypodermic injection of normal blood serum accelerates clotting and it has been employed as a practical remedy in the treatment of hemorrhage. Normal horse serum is upon the market for this purpose and is given in doses of from 10 to 30 cc. (3 to 8 fluidrachms). (See *Blood.*) More recently, on the theory that thromboplastic substance is identical with *kephalin,* various extracts of the ox brain, which tissue is especially rich in kephalin, have been placed upon the market either under the name of kephalin or thromboplastin. There is much evidence, both clinical and experimental, that these preparations increase the rapidity with which the blood clots, either when applied locally or when administered systemically. According to the researches of Hanzlik and Weidenthal (*J. P. Ex. T.,* 1919, xiv, 157), thromboplastin very greatly accelerates the coagulation either of normal blood or of blood whose clotting has been retarded by the addition of oxalic acid or peptone. These authors find that the solution loses its efficiency on keeping; samples 9 months old possess less than one-half of their original power.

As these preparations contain relatively small amounts of protein, there is little danger of anaphylactic reactions following their use. As there is much difficulty in producing sterile solutions of brain extract manufacturers of these preparations make two grades, one intended for systemic use and which is very carefully sterilized, and the other intended for local application. Thromboplastin occurs as whitish, opalescent fluid of a neutral reaction, with the odor of cresol which has been added as a preservative. It has been used successfully in the treatment of *hemorrhages* of various kinds, either for local application or by hypodermic injection. It is recommended that in external hemorrhages, such as *epistaxis,* cotton or gauze saturated in the solution be applied to the bleeding point. In hemorrhage from the stomach it may be administered by the mouth. In *hemoptysis* and other internal hemorrhages it may be administered subcutaneously in *doses* of 20 cc. (5½ fluidrachms).

Thymoacetol.—This is stated to be a derivative of thymotic acid. *Thymotic acid* bears the analogous relation to thymol that salicylic acid does to phenol.

Thymoacetol is a white crystalline powder insoluble in water but soluble in alcohol with a melting point of 75° C. It has been suggested as a local anesthetic.

Thymol Carbonate. *Thymol Urethane. Thymolcarbonic Ether. Thymotal. Tyratol.* $CO(NH_2)O.C_{10}H_{13}$.—J. F. Pohl, by the same process by which guaiacol is converted into guaiacol carbonate, has produced from thymol a nearly tasteless, colorless, crystalline compound of neutral reaction, fusing at 49° C. It is slightly soluble in water, but is decomposed by the alkaline juices of the intestine, thymol being liberated. It is claimed that this substance is as effective as thymol against the *anchylostoma,* and, owing to its not dissolving in the stomach, is much less apt to produce disagreeable symptoms. (*A. J. P.,* March, 1901, 143.) *Dose,* for adult, thirty grains (2 Gm.) three times a day for four days, followed by brisk purgation.

Thymolphthalein.—This compound, which is analogous in its structure to phenolphthalein, occurs in colorless needles melting at 245° to 246° C. It is readily soluble in alcohol or acetone but practically insoluble in water. In the presence of alkalies, however, it dissolves, forming blue solutions. It is widely employed as an indicator in alkalimetry.

Thyresol. *N. N. R.* 1924. $C_{15}H_{23}O.CH_3$.—The *methyl ether of santalol* is an almost colorless fluid. Sp. gr. 0.93–0.94, boiling point 149°–156° C. at 16 mm. pressure. The preparation is practically insoluble in water, but dissolves to a clear fluid in all proportions in alcohol, ether, and oils. It has a slight sandal-wood odor. It has been used by Knauth (*D. M. W.,* 1909), and others, as a substitute for santalol in the treatment of *urethritis.* According to Knauth it is not split up in the organism but appears in the urine in combination with glycuronic acid.

Tilia. *Basswood. Lime. Linden Tree.*—The dried flowers of *Tilia europæa* L., *T. platyphyllos* Scop. and of other species of *Tilia* (Fam. *Tiliaceæ*), are official in the German Pharmacopœia under the head of *Flores Tiliæ.* This drug consists of long-peduncled, pendulous cymes of small yellowish or greenish-white flowers, the peduncle adnate to a strap-shaped bract for about half of its length. Each flower has 5 sepals and 5 petals. The 5 original stamens, by chorisis have each developed a cluster and at the base occurs in addition, a spatulate petal-like body opposite each of the petals. The pistil has a 5-locular ovary which is surmounted by a single style and a 5-toothed stigma. The flowers contain a colorless, fragrant, volatile oil. The bark has been said to contain a neutral body, *tiliadin*, and a glucoside, *tilicin.* (See *A. J. P.*, 1890; *P. J.*, lxvi, 105.) The infusion is used as a household remedy to relieve hysteria and indigestion.

Timbo.—This name is applied in Brazil to various sapindaceous plants, used as fish poisons. Among these is *Serjania curassavica* Radlk. (*Paullinia pinnata* L.), in which Stanislaus Martin (*B. G. T.*, xcii) has found an alkaloid, *timbonine;* F. Pfaff has obtained from a *timbo* of unknown origin two alkaloids, *timboin* and *anhydrotimboin,* also an oily compound, *timbol.* (*A. J. P.*, Nov., 1891.)

Tin. (Sn. At. wt., 118.1.) *Stannum. Etain,* Fr. *Zinn,* G.—This was recognized in the old Edinburgh and Dublin Pharmacopœias, and in the U. S. of 1850, but is no longer official. It has, however, too long ranked among recognized remedies to be passed without notice. Tin is one of the metals which have been known from the earliest ages. It exists generally as an oxide (in *stone* and *wood tin*), rarely as a sulphide (*tin pyrites*), and is by no means generally diffused. It is found in England, Spain, Germany, Bohemia, and Hungary, in Europe, and sparingly in some parts of the United States; in the island of Banca and the Peninsula of Malacca in Asia; in Bolivia, and at Durango in Mexico. The mines of Banca furnish the purest tin. The metal is extracted from the native oxide. When this occurs in its purest state, in detached roundish grains, called *stream tin,* the reduction is affected by heating with charcoal. When the common oxide, called *mine tin,* is reduced, it requires to be freed, by pounding and washing, from the adhering gangue, after which it is roasted to drive off sulphur, arsenic, and antimony, and finally reduced in furnaces by means of stone coal. The metal, as thus obtained, is called *block tin,* and is not pure. The purest kind of tin known in commerce is called *grain tin.*

Tin is a malleable, rather soft metal, of a silver-white color. It may be beaten out into thin leaves, called *tin foil.* It undergoes a superficial tarnish in the air. Its taste is slight, and when rubbed it exhales a peculiar odor. Its ductility and tenacity are small; when bent to and fro, it emits a cracking noise, which is characteristic. Its sp. gr. is 7.29, melting point 235° C., and it volatilizes at a white heat. If forms two oxides. The *stannous oxide*, SnO, is of a grayish-black color. When perfectly pure it has, according to Roth, a red color. *Stannic oxide*, SnO_2, or *dioxide*, forms two hydrates, both being acids—*stannic acid*, $SnO_2.H_2O$, and *metastannic acid,* $Sn_5O_{10}.5H_2O$, or $(H_2SnO_3)_5$.

The tin of commerce is often impure, being contaminated with other metals, introduced by fraud or present in consequence of the mode of extraction from the ore. A high specific gravity is an indication of impurity. When its color has a bluish or grayish cast, the presence of copper, lead, iron, or antimony may be suspected. Arsenic renders it whiter, but at the same time harder, and lead, copper, and iron cause it to become brittle. Pure tin is converted by nitric acid into a white powder (*metastannic acid*), without being dissolved. Boiled with hydrochloric acid, it forms a solution which yields a white precipitate with potassium ferrocyanide. A blue precipitate with this test indicates iron, a brown one copper, and a violet-blue one both iron and copper. If lead be present, a precipitate will be produced by magnesium sulphate. The Malacca and Banca tin and the English grain tin are the purest kinds found in commerce. Banca tin, from analyses by Mulder, appears to be particularly pure, containing only one twenty-fifth of one per cent. of foreign metals. Block tin and the metal obtained from Germany are usually of inferior quality.

Tin enters into the composition of bronze, bell metal, pewter, and plumber's solder. It is used also in making tin plate, which is sheet iron coated with tin, in making tin amalgam for silvering looking glasses, and in forming the *solution of stannous chloride* (*bichloride of tin*), a combination essential for the dyer's use. Being unaffected by weak acids, it forms a good material for vessels intended for boiling operations in pharmacy. A *false tin foil* is considerably used at present, made by coating lead with tin, and then rolling it out into thin sheets. As tin foil is employed for enclosing medicinal powders and perishable articles of food and medicine, care should be taken not to use this substituted preparation.

Powder of Tin. Stanni Pulvis.—For directions for making, see *U. S. D.*, 16th edition. Powder of tin was used as a mechanical anthelmintic, but has very properly gone out of vogue. The *dose* is half an ounce, mixed with molasses, given for several successive mornings, and then followed by a brisk cathartic purge.

There is strong evidence that the salts of tin are poisonous if they enter the circulation and several cases in which the symptoms have been referred to absorption of tin from canned foods have been reported. While it may be possible that these cases were properly diagnosed the enormous use of tin plated metal and the extreme rarity of any ill effects would seem to demonstrate that the danger is remote. For literature on this subject and report of a case of poisoning see Salzer (*J. A. M. A.*, 1918, lxx, 980).

Frouin (*Press. Méd.*, 1917, xxv, 401) asserts that tin has specific antagonistic properties to the staphylococcus and has used a mixture of tin and its oxide in the treatment of *furunculosis* with gratifying results. *Stannoxyl* is a proprietary preparation of tin oxide intended for medicinal use. *Stannous chloride,* or *chloride of tin,* is a violent irritant and mild caustic. Chemically pure tin, given internally, is probably not absorbed. (See 16th edition, *U. S. D.*)

Tinospora. *Gulancha. Br. Add.* 1900.—"The dried stem of *Tinospora cordifolia* Miers (Fam. *Menispermaceæ*), collected in the hot season." *Br. Add.*, 1900. *Tinosopora* has long been used in India as a medicine and in the preparation of a starch known as *gilœ-ka-sat* or as *palo.* It is said to be a tonic, antiperiodic, and a diuretic. Flückiger obtained from it traces of an alkaloid, probably berberine, and a bitter glucoside. The Br. Add., 1900, recognized an *infusion* (*Infusum Tinosporæ* Br. Add., 1900, two ounces to the pint), *dose,* one-half to one fluidounce (15–30 cc.); a *tincture* (*Tinctura Tinosporæ* Br. Add., 1900, four ounces to the pint), *dose*, one-half to one fluidrachm (1.8–3.75 cc.); and a *concentrated solution* (*Liquor Tinosporæ Concentratus* Br. Add., 1900), *dose*, one-half to one fluidrachm (1.8–3.75 cc.). *Tinospora crispa* Miers, which is abundant in the Philippines, is used freely by the natives under the name of *makabuhay* (that is, "You may live"), as a panacea, especially valuable in *general debility*, in chronic *rheumatism*, and in *malarial fevers*. It may be prepared in the same way and given in the same doses as *Tinospora cordifolia*.

Tissa. *Tissa rubra* (L.) Brit. [now *Spergularia rubra* (L.) J. and C. Presl.] (Fam. *Caryophyllaceæ*), a native of Malta, Sicily, and Algiers, is found growing in dry, sandy soil from Quebec to Virginia. It is a low annual with linear, opposite leaves and small pale red flowers. It has long been used as a popular remedy in diseases of the bladder. It has shown by F. Vigier (*J. P. C.*, 1879, ii, p. 371) to contain a resinous aromatic substance which is probably its active principle. It was strongly recommended by Bertherand in *calculous diseases* and acute and chronic *cystitis*. The aqueous extract may be given in *doses* of thirty grains (2.0 Gm.); or the fluidextract, *dose*, a fluidrachm (3.75 cc.), three or four times a day.

Titanium. Ti = 48.1.—A hard, gray-colored metal in powdery fragments, specific gravity 3.589. It is soluble in warm hydrochloric acid. Pick (*Med. Klin.*, 1911) has used various salts of titanium, especially the sulphate and salicylate, with asserted benefit as local remedies in the treatment of *eczema, lupus, rhinitis* and *conjunctivitis*. On the skin he uses solutions of from one-quarter to one-half per cent. of titanium sulphate, which must be freshly made, as the salt is decomposed by water. For mucous membranes the solution may vary in strength from one-twentieth to one-tenth of one per cent.

Tobacco. *Tabacum. U. S.* 1890. *Nicotiana Tabacum* L. (Fam. *Solanaceæ.*)—This is the commonly cultivated *tobacco* plant of the United States, Cuba and the Philippines. It is an annual in the U. S., but in the tropics becomes bi- or triennial. It has a large, fibrous root, and an erect, round, hairy, viscid stem, which branches near the top, and rises from three to six feet in height. The leaves are numerous, alternate, sessile, and somewhat decurrent, very large, ovate-lanceolate, pointed, entire, slightly viscid, of a pale green color, and have a narcotic odor. The flowers appear in panicles or racemes and vary from pink to red in color.

There is good reason to believe that this plant is a native of tropical America. Columbus, upon landing at St. Domingo in 1492, found the natives smoking cylinders of tobacco leaves. Tobacco is at present cultivated in most parts of the world, and nowhere more abundantly than within the limits of the United States. The young shoots, produced from seeds thickly sown in beds, are transplanted into the fields during the month of May, and set in rows with an interval of three or four feet between the plants. Through the whole period of its growth the crop requires constant attention. The development of the leaves is promoted by removing the top of each plant and thus preventing it from running into flower and seed. The harvest is in August. The ripe plants, having been cut off above their roots, are dried under cover, and then stripped of their leaves, which are tied in bundles and packed in hogsheads. While hung up in the drying houses, they undergo a curing process, consisting in exposure to a considerable degree of heat, through which they become moist, or, in other words, are said to sweat, after which they are dried for packing.

Other species also of *Nicotiana* are cultivated, especially *N. rustica* L., which yields the Turkish tobacco and is said to have been the first introduced into Europe. This species was cultivated by all of the North American Indian tribes from the Mississippi eastward to Atlantic Ocean. It is naturalized near the borders of some of our small northern lakes. The *N. quadrivalvis* of Pursh affords tobacco to the Indians of the Missouri and Columbia Rivers; and *N. fruticosa*, a native of China, was probably cultivated in Asia before the discovery of this continent by Columbus. Besides these there are *N. Persica* Lindl., cultivated in Persia, and is the source of Persian tobacco; *N. repanda* Willd., cultivated in central and southern North America; *N. Bigelovii* Wats., of North America. It is very doubtful, however, whether these plants furnish any large part of the commercial tobacco. Latakia tobacco seems to be the product of the *N. Tabacum*, and Senator Vidal asserts that *N. repanda* is not found in Cuba, *N. Tabacum* being the only species there cultivated. (*P. J.*, viii, 710.) Again, the Persian and Turkish tobacco sold under the name of *tumbeki*, which has been variously attributed to *N. Persica* and to *N. rustica*, is in all probability the product of *N. Tabacum*. (*Kew Bulletin*, April, 1891.)

Tobacco, as it occurs in commerce, is of a yellowish-brown color, a strong narcotic penetrating odor which is wanting in the fresh leaves, and a bitter, nauseous, and acrid taste. These properties are imparted to water and alcohol. They are injured by long boiling, and the extract is, therefore, relatively feeble. The most important constituent is the liquid alkaloid, *nicotine*, discovered by Posselt and Reimann in 1828. This is easily extracted from tobacco by means of alcohol or water as a malate, from which the alkaloid can be separated by shaking it with caustic soda solution and ether. The ether is then expelled by warming the liquid, which finally has to be mixed with slaked lime and distilled in a stream of hydrogen, when the nicotine begins to come over at about 200° C. The percentage of nicotine in tobacco varies considerably—from 1.62 per cent. in Havana tobacco and 2 per cent. in Maryland tobacco to 6 per cent. in Virginia tobacco and 8 per cent. in Kentucky tobacco. For modes of estimating the proportion of nicotine in tobacco, see Harrison and Self, *P. J.*, June 1, 1912 and Thomsen, *Chem. Ztg.*, 1917, xli, 476.

Nicotine (*Nicotina* or *Nicotia.*) $C_{10}H_{14}N_2$. β-pyridyl-*a*-*n*-methyl-pyrrolidine.—This is a colorless, lævorotary, fluid, of the sp. gr. 1.010, boiling at 247° C., and not solidifying at –10° C.; having a faint odor when cold; of an exceedingly acrid, burning taste, even when largely diluted; entirely volatilizable, and, in the state of vapor, very irritant to the nostrils, with an odor recalling that of tobacco; inflammable; very soluble in water, alcohol, ether, the fixed oils, and oil of turpentine; strongly alkaline in its reaction, and capable of forming crystallizable salts with the acids. These salts are deliquescent, having a burning and acrid taste, and, like the salts of ammonia, lose a portion of their base by heat. It has been prepared synthetically by Pictet. On treatment with oxidizing agents, nicotine yields *nicotinic* or *β-pyridinecarboxylic acid*, $C_5H_4N.COOH$. In its action on the animal system it is one of the most virulent poisons known. A drop of it, in the state of concentrated solution, is sufficient to destroy a dog, and small birds perish at the approach of a tube containing it. Tannin forms with it a compound of but slight solubility, and might be employed as an antidote. Nicotine has been found in the seeds, and, in very small proportion, in the root. Nicotine has the remarkable property of resisting decomposition amid the decaying tissues of the body, and was detected by Orfila in the bodies of animals destroyed by it two or three months after their death.

Although Thoms (*A. J. P.*, 1900, p. 227) was unable to detect any nicotine in tobacco smoke, there is no room for doubt that it is present in sufficient amount to be injurious. Lehmann (*P. J.*, Sept. 18, 1909) finds that about 95 per cent. of the nicotine in tobacco passes over into the smoke, and Toth (*Chem. Ztg.*, 1909, p. 866) has shown that the large proportion of nicotine exists in the smoke in uncombined state. Baumberger (*J. P. Ex. T.*, 1923, xxi, p. 23) as a result of his own studies and an extensive review of the literature, reaches the conclusion that in continuous smoking from 27 to 36 milligrammes of nicotine are absorbed per hour.

Nicotimine, isomeric with *nicotine*, *nicoteine* $C_{10}H_{12}N_2$ and *nicotelline* $C_{10}H_8N_2$ are other alkaloids present in tobacco. The bases *pyrrolidine* C_4H_9N and methyl *pyrroline* C_5H_9N are also said to be present.

When distilled at a temperature above that of boiling water, tobacco affords an empyreumatic oil, which was official in the U. S. P., 1870, under the name of *Oleum Tabaci: Oil of Tobacco.* It is highly poisonous, probably from containing nicotine. For further information on the chemistry of nicotine and related alkaloids, see the papers of Pictet and co-workers (*B. Chem. G.*, 1895, xxviii; 1904, xxxvii; *A. Pharm.*, 1906, ccxlix.

It is quite certain that tobacco leaves undergo considerable chemical changes during the processes of curing and preparation for use. Thus, the characteristic odor of ordinary tobacco is entirely different from that of the fresh leaves, and must be owing to the generation of a new volatile principle. The proportion of nicotine is probably slightly diminished by the process of "curing."

Tobacco is locally irritant. Snuffed up the nostrils, it excites violent sneezing, and a copious secretion of mucous; chewed, it irritates the mucous membrane of the mouth and increases the flow of saliva; when injected into the rectum, it sometimes operates as a cathartic; and the alkaloid nicotine injected into the cellular tissue of animals evidently produces much pain. In large doses, or in persons unaccustomed to it, tobacco produces severe nausea, sometimes vomiting, accompanied with profuse perspiration, and great muscular weakness. The alkaloid nicotine is a virulent poison. It primarily excites, and secondarily paralyzes, the ganglia upon the sympathetic nerves, stimulates the intestinal muscles, and, in sufficient quantities, has a paralytic action upon the motor nerves. As a result of its action upon the sympathetic ganglia, it causes contraction of the blood-vessels with marked increase in the blood pressure, followed, after large doses, with vascular dilatation and fall of pressure. The pulse rate is at first decreased, later becomes rapid. There is primary increase in the secretion of the salivary and probably of the other glands, followed, after large doses, by paralysis of secretion.

The use of tobacco was adopted by the Spaniards from the American Indians. In the year 1560 it was introduced into France by the ambassador of that country at the court of Lisbon, whose name —Nicot—has been perpetuated in the generic title of the plant. Sir Walter Raleigh is said to have introduced the practice of smoking into England. In the various modes of smoking, chewing, and snuffing, the drug is now largely consumed in every country on the globe. It must have properties peculiarly adapted to the propensities of our nature to have thus surmounted the first repugnance to its odor and taste and to have become the passion of so many millions. Whether or not nicotine plays any part in the pleasurable effects of tobacco is, despite considerable research and discussion, unsettled, but it is generally agreed that the evil effects of excessive indulgence are due to this alkaloid. The most important disturbances produced are in the digestive and circulatory organs. As a result of the disturbed innervation of the heart, palpitation and cardiac irregularities are common, and the vascular contraction is generally regarded as one of the causes of arterial degenerations.

Formerly much used as a relaxant, tobacco has been superseded by safer and more efficacious remedies, so that it is at present never employed in medicine, except occasionally in *chronic asthma.* It should always be borne in mind that its active principle is absorbed readily by the skin, and that serious or even fatal poisoning may result from its too free application to the surface of the body. A case of death is on record, occurring in a child eight years old, in consequence of the application of the expressed juice of the leaves to the head, for the cure of *tinea capitis.* Death has also been produced by the inhalation of the smoke.

From five to six grains (0.32–0.4 Gm.) of powdered tobacco will generally act as an emetic; but should never be used for this purpose.

Toddalia. *Br. Add.* 1900.—"The dried root-bark of *Toddalia aculeata* Lam." (Fam. *Rutaceæ.*) This climbing shrub, known also as *Lopez root*, growing in East Africa, Madagascar, the subtropical Himalayas, Ceylon, and the Philippines, is a tonic stomachic, containing berberine, a resin and a volatile oil, which may be readily obtained from the leaves by distillation. This oil has the odor of citron peel, and a bitter, aromatic taste. See also *Schim. Rep.*, 1906, 82, and 1912, 121. The British Addendum recognized an *infusion* (*Infusum Toddaliæ*, two ounces to a pint), *dose*, one to two fluidounces (30–60 cc.); also a *concentrated solution* (*Liquor Toddaliæ Concentratus*, Br. Add., 1900), *dose*, from one-half to one fluidrachm (1.8–3.75 cc.).

Tonka Bean. *Tonco Bean. Tonquin Bean. Semina Tonco. Fève Tonka*, Fr. *Tonka-bohnen*, G.—The seeds of *Coumarouna odorata* of Aublet, a large tree native to Guiana which yields the Dutch Tonka Bean; and of *C. oppositifolia* (Aubl.) Taub (*Dipteryx oppositifolia* Willd.) (Fam. *Leguminosæ*), a tree indigenous to Brazil, which is the source of the English tonka bean. The fruit is an oblong-ovate pod, enclosing a single seed, from 3 to 4 cm. long and about 1 cm. wide, usually somewhat compressed, with a dark brown, wrinkled, shining, thin, and brittle skin, and a light brown, oily kernel. The seed has a strong, agreeable, aromatic odor, and a bitterish, aromatic taste. Its active constituent is a crystallizable, odorous substance, called *coumarin* or *cumarin*, $C_9H_6O_2$ (see Part I). It is sometimes found in a crystalline state, between the two lobes of the kernel. For methods of obtaining coumarin from tonka bean see *U. S. D.*, 20th ed., p. 1646. One pound of the beans yields about 108 grains of coumarin. Tonka bean is used to adulterate tincture and extract of vanilla and to flavor snuff, being either mixed with it in the state of powder or put entire into the snuff box. *Tonquin butter* is an article of commerce in Holland. It is the fatty substance of tonka beans; it was analyzed by M. Duyk, it has the sp. gr. of 0.888, melting point is 28° C., saponification number 25.7. (*Rep. de Pharm.*, 1908.)

The fluidextract of the bean has been used with asserted advantage in *whooping cough* in *doses* equivalent to from five to eight grains (0.32–0.5 Gm.) for children five years old. (*A. J. P.*, 1869, 27.)

Toramin is the ammonium salt of malonic acid trichlorbutyl ester. $CH_2.COONH_4.COOC.CCl_3$-$(CH_3)_2$. It occurs in pearly scales, melting point 116° C. It is used as a cough sedative in *bronchitis*, especially in conjunction with expectorant drugs, in doses of 0.1 to 0.2 Gm. (1.5 to 3 grains).

Tormentil. *Rhizoma Tormentillæ*, P. G. *Tormentille*, Fr. *Tormentillwurzel*, G. *Tormentilla*, It. *Tormentila*, Sp.—Various species of the rosaceous genus *Potentilla* have been employed in medicine. (See *A. J. P.*, 1875, 109.) It is asserted that our common *P. canadensis* L. is a valuable sudorific and diuretic.

Potentilla Tormentilla Neck. (*Tormentilla erecta* L., *T. officinalis* Curt.)—The *tormentil*, or *septfoil*, which was formerly in the Secondary List of the U. S. Pharmacopœia, is a small perennial plant of Europe and Asia. All parts of the plant are astringent, especially the rhizome, which is the part employed. The rhizome of *tormentil* is cylindrical, somewhat fusiform, branching and more or less curved, from 2.5 to 8 cm. long, and from 0.5 to 1.5 cm. thick, brown or blackish externally, and reddish within. It has a slight aromatic odor and a very astringent taste. It contains a red coloring principle, soluble in alcohol, but insoluble in water, which appears to be identical with rhatany-red (see *Krameria*) and considerable quantities of a peculiar tannin (*tormentil-tannic acid*, $C_{26}H_{22}O_{11}$). *Kinovic acid*, $C_{24}H_{38}O_4$, and small quantities of *ellagic acid*, $C_{14}H_6O_8$ are also present. The root is said to be used for tanning leather in the Orkneys and Western Islands of Scotland, and for staining leather red by the Laplanders. Tormentil is a simple and powerful astringent, applicable to all cases of disease in which this class of medicines is indicated. It may be given in substance, decoction, or extract. The *dose* of the powder is from thirty grains to a drachm (2.0–3.9 Gm.).

Toxicodendron Capense Thunb. (*Hyænanche capensis* Pers.) *Hyena Poison.* (Fam. *Euphorbiaceæ.*)—The fruits of this small South African tree are said to be used for the poisoning of hyenas. They have been investigated by von Engelhardt (*Kobert's Arbeiten*, 1892), who finds in them a neutral, bitter principle, *hyananchin*, which is a powerful poison, resembling strychnine in its physiological action, from which, however, it differs in that it powerfully affects the cerebrum. The convulsions which it produces are of central origin, the poison having no action upon the nerve trunks or the muscles.

Tradescantia Erecta Jacq. (Now *Tinantia fugax* Scheidw.) (Fam. *Commelinaceæ.*)—The natives of South America used an extract of this herb as a hemostatic in cock-fights and it has lately been introduced into medicine, being especially recommended in *hemorrhages* of the ear and the upper air passages. Nothing definite is known of its actual composition and its styptic virtue has been ascribed, by some, to its tannin content. For description of *Commelina communis*, a perennial herb of the United States, see Preston, *A. J. P.*, 1898, p. 321.

Tragoponic Acid.—This was found by Rademaker and Fisher in the seeds of *Tragopogon porrifolius* L. (Fam. *Compositæ.*) This plant, commonly called *Salsify, oyster plant*, furnishes an edible root. (See *Nat. Drug.*, July 23, 1886, 47.)

Traumatol. *Iodocresine. Iodocresol.* $C_6H_3I.$-$(CH_3)OH$.—This occurs as a purplish-red or yellow powder; it is obtained by acting on cresol with iodine, and is used as a substitute for iodoform.

Tribrom Beta-naphthol. $C_{10}H_4Br_3OH$.—This occurs as a grayish crystalline powder, readily soluble in alcohol, ether and the alkalies. Lehmann (*Beitr. Klin. Chir.*, 1911, xlvii) has used it for the purpose of disinfecting the hands of the surgeon. He uses an alcoholic solution containing 0.5 per cent.

Tribromhydrin. *Tribromhydrinum. Allyl Tribromide. Tribromallyl. Tribrompropane. Propargyl Tribromide.* $CH_2Br.CHBr.CH_2Br$.—This substance is a colorless or faintly yellowish liquid at the ordinary temperature, but solidifying when cooled below 10° C. to a mass having a specific gravity of 2.430 at 15° C. Its boiling point is about 220° C. and is soluble in alcohol or ether. It has been recommended by De Fleury as a nerve sedative in *hysteria, asthma, whooping cough*, and other nervous disorders. It may be administered by mouth in capsules containing each five drops (0.25 cc.), of which one or two may be given several times a day. It has also been employed subcutaneously in two to three minim (0.12–0.2 cc.) doses in 20 minims of ether. (*Ph. Post*, Dec., 1888.)

Tribromphenol. $C_6H_2Br._3.OH$. *Bromol.*—This is prepared by shaking a solution of phenol with bromine water. It occurs in the form of soft, white, colorless needles, melting at 95° C., and subliming undecomposed at a higher temperature. It is practically insoluble in water but soluble in alcohol, ether or chloroform. In caustic alkaline solutions it is readily soluble, and from them it is separated unaltered by acids. The odor is disagreeable, like that of bromine, but more penetrating; the taste is sweet and astringent.

Bechold and Ehrlich (*Cb. C.*, 1906, xlvii) have found that tribromphenol will inhibit the growth of bacteria when present in 1 part in 10,000. Grimm, who recommends tribromphenol as a surgical antiseptic, states that a half per cent. solution will kill the bacteria of putrefaction in an hour. According to Grimm and Rademacher, tribromophenol, when in concentrated form, acts as a caustic, and is especially valuable in the treatment of *tuberculous ulcers* and *gangrene*. Grimm considered the remedy too caustic to be used upon the mucous membrane of the upper air-passages, but Rademacher has used it in the solution of olive oil (2 to 30) with asserted excellent results in *diphtheria.* It is said to be very slowly acted upon by the intestinal juices, and has been used as an intestinal disinfectant in *doses* of from three to eight grains (0.2–0.5 Gm.) a day. That it is absorbed in some form is shown by the fact of its excretion in the urine in the form of *tribromophenol-sulphonic acid.*

Triferrin, or *paranucleinate of iron,* contains about 22 per cent. of iron as well as 2.5 per cent. of organically combined phosphorus and is prepared from casein of cow's milk by digestion and precipitation by means of ferric salts. *Triferrin* is freely and completely soluble in a weak solution of sodium hydroxide, but it is insoluble in diluted hydrochloric acid having the acid strength of normal gastric juice. *Dose,* five grains (0.32 Gm.).

Trigemin. *Dimethyl-amido-antipyrin-butyl-chloral Hydrate.* $C_{17}H_{24}N_3O_3Cl_3$.—A product of the action of butyl chloral hydrate on pyramidon, forming long white needles, fusing at 85° C. and possessing a delicate aromatic odor and a mild taste. It has been used as an analgesic in all those forms of pain for which the coal-tar derivatives are valuable. It is incompatible with spirit of nitrous ether, acacia and most of the chemicals that are so with antipyrin. The *dose* is from three to fifteen grains (0.2–1.0 Gm.).

Trigonella. *Greek Hay Seed. Fenugreek. Semen Fœnugræci. Bockshornsamen,* G. *T. Fœnum-græcum* L. (Fam. *Leguminosæ.*)—A low European annual herb with pinnately 3-foliate leaves, obscurely dentate, obovate, leaflets and white flowers, cultivated in southern Europe, northern Africa and India for its seeds. These are oblong-quadrangular, somewhat compressed, obliquely truncated at each extremity, 3 to 5 mm. in length and 2 mm. broad, brownish-yellow externally, internally yellow, and marked with an oblique furrow running half their length. They have a strong peculiar odor resembling that of elm bark, and an oily, bitter, farinaceous taste, and contain fixed and volatile oils, mucilage, bitter extractive and a yellow coloring substance. E. Jahns (*B. Chem. G.,* 1886, xviii and 1887, xx, p. 2840) has obtained choline, and *trigonelline,* $C_7H_7O_2N$. The yield of the former was 0.05 per cent., and of the latter 0.13 per cent. Trigonelline is a betäine of nicotinic acid. It is found in several other plants and appears to be the same as caffearine found in coffee (Gorter, *Ann. Chem.,* 1910, ccclxxii, 237).

An ounce of the seeds, boiled in a pint of water, renders it thick and slimy. They yield the whole of their odor and taste to alcohol. On the continent of Europe they are employed in the preparation of emollient cataplasms, enemata, ointments and plasters. They are never used internally for human beings, but the ground seeds are used to an enormous extent in the manufacture of cattle powders or condition powders and the decoction or fluidextract for making *imitation maple flavor.*

Trimethol. *Trimethyl-methoxyphenol.* $C_6H(CH_3)_3OCH_3OH$.—This compound is asserted to be an extremely powerful disinfectant having a phenol coefficient of 40. It is recommended as an intestinal antiseptic in *doses* of 1 to 2 grains (0.06 to 0.12 Gm.). It is on the market in the form of capsules and as a syrup.

Trimethylamine. *Secaline.* $CH_3CH_3CH_3N$.—This substance which has been so often confused with propylamine (see p.) is a colorless liquefiable gas of a fishy ammoniacal odor, soluble in water and alcohol and having at 0° C. specific gravity of 0.673, boiling at 9° to 10° C. and possessing extremely toxic properties. It was first prepared by Wertheim in 1850 from narcotine and was given the name *metacetamine.* The common method of preparing this substance at the present time is by the action of ammonia gas on methyl iodide. The aqueous solution of *trimethylamine* is often miscalled "propylamine," which is a primary compound of ammonia (*monamine*), whereas the trimethylamine is a tertiary compound ammonia (triamine). It is not used medicinally.

The hydrochloride, $(CH_3)_3NHCl$, is used as an odorous addition to bait, to lure fish.

Trinitrotoluene. *T.N.T.*—This substance which is used as an explosive has the formula of $C_6H_2(NO)_3CH_3$. To explode it it is necessary to have a certain degree of heat combined with concussion. Heat alone causes it to burn like camphor. Workers in munition plants who are exposed to the inhalation of T.N.T. dust or fumes suffer with severe, and often fatal poisoning. The symptoms are divisible into two groups, those due to local irritation, as lachrymation, dry cough, with a yellow bitter sputum and occasionally epistaxis; there is also irritation of the skin with eczematous eruptions. In this group of cases there are also often digestive disturbances, cramp-like pains in the abdomen, constipation followed by diarrhea and sometimes vomiting. The second group of toxic symptoms were due to the action of the drug upon the liver and consist of nausea, vomiting and jaundice, mental disturbance, blurred vision and sometimes peripheral neuritis. A fatal case reported by Maitland (*J. A. M. A.,* 1917, lxviii, p. 835) showed a small contracted liver with cloudy swelling and fatty degeneration of the parenchyma followed by necrosis of the cells. Panton (*L. L.,* 1917, ii, p. 77) has found the blood, even of apparently healthy workers in T.N.T. factories frequently to be bile tinged. Finding also that many of these patients were anemic he believes that the poison may exercise a destructive action on the bone marrow. He divides types of T.N.T. poisoning into three groups: (1) Severe gastric disturbance without jaundice or anemia, (2) anemia of the aplastic type, and (3) jaundice.

Minot (*J. A. M. A.,* Aug. 30, 1919) as the result of an examination of over 200 unselected workers in T.N.T. finds frequent evidence of destruction of the red blood cells such as the presence of fragmented cells in the blood or various forms of abnormal cells.

The skin and hair of T.N.T. workers become stained a characteristic yellowish-orange color which may be removed by oils or various organic solvents.

Triosteum. *T. perfoliatum* L. *Horse Gentian. Bastard Ipecac. Tinker's Weed. Wild Coffee. Fever Root. Feverwort. Wild Ipecac. Racine de Trioste,* Fr. *Dreisteinwurzel,* G. (Fam. *Caprifoliaceæ.*)—This coarse perennial herb is found in rich woods from Massachusetts to Alabama and westward to Nebraska, preferring a limestone soil and shady situations. The rhizome and roots represent the drug. The rhizome is of horizontal growth, subcylindrical and knotty, 15 cm. long about 15 mm. thick; externally yellowish-brown, showing prominent cup-shaped stem scars on its upper surface and numerous rootlets about 5 mm. thick on its lower surface; internally with thin bark and broad whitish wood and pith. When dry it is brittle and easily pulverized. It has a sickening odor, and a bitter, nauseous taste. It is said to contain an alkaloid which Andree believed to be identical with emetine, but which Hartwich has shown to be different. It yields its active properties of both water and alcohol. Triosteum is cathartic, and is large doses emetic and perhaps diuretic. The bark of the root may be given in *doses* of twenty to thirty grains (1.3–2.0 Gm.), or the extract in half the quantity. For uses, see *A. J. P.*, 1891, 326.

Tripoli. *Terra Tripolitana.*—An earthy mineral, of a whitish, yellowish, or pale straw color, sometimes inclining to red or brown, usually friable, often adhesive to the tongue, and presenting the aspect of argillaceous earth, though differing from clay by the roughness and hardness of its particles, and by not forming a paste with water. The *Venice tripoli* is said to come from Corfu. Tripoli is sometimes artificially prepared by calcining certain argillites. It is used for cleaning and polishing metals.

Trompatila.—This is the stem and branches of *Bouvardia triphylla* Salisb. (Fam. *Rubiaceæ*), a Mexican plant used by the natives for *hydrophobia.* (*A. J. P.*, 1874, 51.)

Tropacocaine. *Benzoyl-pseudotropeine.* $C_8H_{14}ON.C_7H_5O$.—This compound, belonging chemically to the class of *Tropeines* (see *Atropine*), was isolated by Geisel from a narrow-leaved coca plant from Java. (*Ber. d. Chem. Ges.*, xxiv, p. 2336.) It is obtained as an oil, which when quite dry solidifies in radiating crystals, melting at 49° C. It has a strong alkaline reaction, and is easily soluble in alcohol, ether, chloroform, benzene, and petroleum benzin. The *hydrochloride*, being freely soluble in water, is usually preferred to the base. It is decomposed by heating with hydrochloric acid into benzoic acid and pseudotropine, $C_8H_{15}ON$.

Tropacocaine resembles cocaine in its stimulant action upon the nerve centers, and also in its local anesthetic action. It differs from cocaine, however, in that it does not cause local constriction of the blood vessels, and that it has very little influence upon the pupil. Sollmann (*J. A. M. A.*, 1918, lxx, 216) has shown that it is approximately equal to cocaine in its anesthetic power and Eggleston and Hatcher that it is distinctly less toxic. It has been used chiefly in the so-called spinal anesthesia and a large number of surgeons have reported favorably upon it. A *dose* of one grain (0.06 Gm.) is ordinarily recommended, although a number of authors have used larger quantities without evil effects. Tropacocaine has been used also as a local anesthetic in ophthalmic and pharyngological practice. It possesses an advantage over cocaine in being more stable in solution and easily sterilizable.

Trypan Blue. *Diamine blue. Congo blue. Azidin blue. Niagara blue. Sodium salt of tolidin-disazo-bi-l-amido-8-naphthol-3-6-disulphonic acid.* $C_{34}H_{24}O_{14}N_6S_4Na$.—It has been used as a dyestuff. Recently a purified form of this dye has been brought forward as a therapeutic remedy in various protozoan infections. It occurs as a bluish-gray powder which forms in water a deep violet-blue solution. It is almost insoluble in alcohol and quite so in ether. We do not know of any reports of its use in human beings, but Evers, Zengel (*B. Thier W.*, 1913) and others have reported rapid cures of both *malaria* and *trypanosomiasis* in the lower animals.

Trypan Red. *Sodium salt of ortho-benzidine-mono-sulpho-acid-disazo-bi-2-naphthylamine-3.6-sulpho-acid.* $C_{10}H_4(NaSO_3)_2NH_2N.N(C_6H_4)(C_6H_3)NaSO_3N.NC_{10}H_4(NaSO_3)_2NH_2$.—By *trypan red* is meant a coloring matter allied to *benzopurpurin B.* or to *Brilliant Congo R.* It is a reddish-brown powder, soluble in water. The aqueous solution is not altered by the addition of acetic acid, but on the addition of a sufficient quantity of hydrochloric acid, the free sulpho-acid is eliminated in blue flakes.

This was brought forward by Ehrlich and Shiga (*B. K. W.*, 1904) as a useful remedy in experimental, and a hopeful remedy in human, *trypanosomiasis.* Jaboulay and one or two other French writers (*Lyons Medicale*, 1905) have used it hypodermically in the treatment of *cancers* with asserted extraordinary benefit, but the remedy has failed to come into general use. Eight grains (0.5 Gm.) of the remedy may be injected hypodermically, dissolved in 40 cc. of physiological salt solution, at intervals of from two to ten days.

Tryparsamide.—The sodium salt of N-phenylglycineamide-*p*-arsonic acid, $C_6H_4(NHCH_2CONH_2).(AsO.OH.ONa)$.—The dried salt contains 25.32 per cent. of arsenic, in the pentavalent form. This compound, which was developed in the Rockefeller Institute for Medical Research, is a colorless crystalline solid freely soluble in water and without odor, taste or local irritant action. It is in its chemical structure more nearly related to atoxyl than to arsphenamine.

Tryparsamide was brought forward as a remedy for *trypanosomiasis* and *syphilis.* Brown and Pierce (*J. Ex. M.*, 1919, xxx, 417 et seq.) find that it has a well marked effect upon the trypanosomes but that its spirocheticidal action is less potent. In a discussion before the American Medical Association (*J. A. M. A.*, 1924, lxxxiii, p. 888 et seq.) the consensus of opinion developed was that in ordinary cases of syphilis the drug was far inferior to arsphenamine but that in those tertiary manifestations involving the central nervous system such as *general paresis, tabes,* etc., it gave better results than any other treatment. A number of cases of disturbance of vision, some with permanent blindness, similar to those caused by atoxyl have been reported. At present the drug is distributed for experimental purposes only. The doses employed have been usually in the neighborhood of 45 grains (3 Gm.) given intravenously at intervals of about one week.

Tulipine.—An alkaloid extracted from the garden tulip, *Tulipa,* and of which there are a number of classes depending upon the order of their flowering. It is said to be a cardiac poison, with remarkable sialagogue properties. (*Nouv. Rem.*, 1886.) Under the name of *chielin* there has been put upon the market a brownish thick extract-like substance of an agreeable odor, easily soluble in water, said to be derived from the bulb of the tulip and to be non-poisonous. It has been highly recommended by H. Heyman as a soothing application in various forms of inflammatory skin diseases. (*D. M. W.*, August, 1902.)

Tussol. *Antipyrine Mandelate. Phenyl-glycolate.* $C_{11}H_{12}N_2O.C_6H_5CH(OH)COOH$.—It forms a white powder, fusing at 52° to 53° C., is soluble in water and incompatible with most of the substances that are incompatible with antipyrine. It is recommended in the treatment of *whooping cough* in the following *doses:* for children under one year, from three-fourths to one and a half grains (0.048–0.096 Gm.); from two to four years, four to six grains (0.26–0.4 Gm.).

Tutty. *Tutia. Impure Oxide of Zinc.*—This oxide is formed during the smelting of lead ores containing zinc. It is deposited in the chimneys of the furnaces, in the form of incrustations, moderately hard and heavy, and studded over with small protuberances of a brownish color on the outside and yellowish within. As it occurs in commerce, the pieces occasionally present a bluish cast, from the presence of small particles of metallic zinc. Sometimes a spurious substance is sold for *tutty,* consisting of a mixture of blue clay and copper filings, made into a paste with water and dried on an iron rod. It is distinguished from the genuine tutty by its diffusing in water and exhaling an earthy odor, and by its greater friability. Tutty was formerly used as an external desiccant. To fit it for medicinal use it must be reduced to fine powder, which is dusted over the affected part, or applied in the form of an ointment. It is used as a metal polish, also as a finger-nail polish.

Tylophora Leaves. *Tylophoræ Folia. Br. Add.,* 1900. (Fam. *Asclepiadaceæ.*)—The dried leaves of *Tylophora asthmatica* (L.) Wight and Arnott, are used in certain parts of India as a poison for vermin, and have been used with fatal results as a poison. This plant, which grows in Bengal, Burma and Ceylon, has been known in Indian medicine since 1780, and has been largely used in both the civil and the military medical service of Madras. It was officially described as "petiolate, entire, from two to five inches (five to twelve and a half centimeters) long and from three-quarters of an inch to two and one-half inches (eighteen to sixty-five millimeters) broad, lanceolate-ovate or ovate or subrotund in outline, somewhat cordate at the base, abruptly acuminated; rather leathery in texture, glabrous on the upper surface, and finely downy on the lower; of a brownish-green color, which is paler on the lower surface. Odor slightly aromatic; almost devoid of taste." *Br. Add.*

David Hooper (*P. J.,* 1891, xxi, 6) has separated from this drug an alkaloid, *tylophorine,* soluble in ether and alcohol, but scarcely so in water; forming crystalline salts, and striking with nitric acid a purplish-red color, with Fröhde's reagents a deep sap-green, and with potassium dichromate and sulphuric acid a dirty violet. Tylophora resembles in its activity ipecac, and is used as a substitute for that drug in *bronchitis* and in *dysentery.* In *doses* of from twenty to thirty grains (1.3–2.0 Gm.) it is used as an emetic. The expectorant *dose* is from one-half to two grains (0.032–0.13 Gm.).

Tyramine. *N. N. R.* 1924.—One of the active bases which was found in ergot by Barger and Dale was *para-hydroxy-phenyl-ethylamine,* $OH.C_6H_4CH_2CH_2NH_2$, which had previously been found by Barger and Walpole as one of the decomposition products in putrid meat infusion. This base is now prepared synthetically, and the hydrochloride is marketed under the trade-name of "*tyramine.*" In a general way the physiological action of tyramine is similar to that of epinephrine, but it is very much less powerful, and produces practically no effect when applied locally to the mucous membranes. Hewlett and Kay (*J. A. M. A.,* 1918, lxx, 1810) have shown that the subcutaneous injection of one grain (0.06 Gm.) of tyramin causes in normal men a marked rise in the blood pressure with increase in the volume of the pulse which lasts for fifteen to thirty minutes. From their clinical experience they conclude that in ordinary circulatory failure, because of the transitoriness of its action, tyramin is not likely to prove a clinically useful remedy, but that in sudden emergencies such as surgical *shock* or circulatory failure occurring during general *anesthesia* the drug may be of practical value. In such cases, from one to one and one-third grains (0.06–0.08 Gm.) may be injected hypodermically and repeated several times at intervals of twenty to thirty minutes as conditions may indicate. Barbour (*J. A. M. A.,* 1917, lxviii, 882) has shown that tyramin is a stimulant to respiration and suggests its combination with morphine to antagonize the depressant influence of the latter on the respiratory center. There is not sufficient clinical evidence to justify a conclusion as to its practical usefulness. The *dose* is from one-third to one grain (0.02 to 0.065 Gm.).

Ulex.—*Ulex europœus* L. (Fam. *Leguminosæ*) is the common *furze, gorse,* or *whin* so conspicuous in the waste places and by the roadsides of Great Britain, from its spiny branches and bright yellow flowers situated on the spines, either solitary or in pairs. The young tops are fed to cattle and horses, but the food value has been questioned. The leaf buds have been used as a substitute for tea and the flowers yield a beautiful yellow dye. In the seeds of this plant, A. W. Gerrard has found an alkaloid, *ulexine.* In 1890 Kobert (*D. M. W.,* 1890), as the result of an elaborate physiological study, came to the conclusion that ulexine is identical with cytisine. The suggestion has given rise to a considerable chemico-physiological discussion, a brief abstract of which may be found in *P. J.,* Feb., 1891. Kobert found indications of a second alkaloid in ulex. Partheil (*A. Pharm.,* 1892, 448; 1894, 486) and Plugge (*A. Pharm.,* 1894, 444) are in accord as to the identity of ulexine and cytisine. Ulexine has been used in cardiac *dropsy* *Dose,* from one-fifteenth to one-twentieth of a grain (0.004–0.003 Gm.).

Ulmaren is the name given by Bourcet to a mixture of the salicylic acid esters of the higher aliphatic alcohols. It has been stated to contain 75 per cent. of salicylic acid. *Ulmaren* is described as a heavy, pale yellowish-red, refractive, neutral, or weakly acid liquid, of pleasant, faint odor recalling salol, and burning taste. Its sp. gr. at 15° C. is 1.06; and its boiling point lies between 237° C. and 242° C. It crystallizes from an equal volume of petroleum benzin, and is almost insoluble in water, but is soluble in alcohol, ether and chloroform. Animal experimentation (*Th. M.,* 1903, xvii) showed that in moderate doses it is well taken, but if given in large doses by the mouth causes in the dog vomiting and purging, and in the rabbit a dose of 0.07 Gm. per kilogramme intraperitoneally injected, caused death from asphyxia. It is recommended to be used as an external application in *rheumatic* and *neuralgic* diseases, as well as in *gout,* either to be painted on the part and covered with waxed paper or used in the form of an ointment made up with lanolin, in which case it should be present in the proportion of 30 per cent. After epidermatic application the salicylic acid reaction may be demonstrated in the urine in three hours and lasts for three days. It is affirmed to have marked analgesic, antipyretic and antirheumatic powers. (*B. G. T.,* June, 1903.) *Dose,* fifteen to forty-five grains (1–3 Gm.); externally thirty to sixty grains (2–3.9 Gm.).

Ultramarine. *Outremer*, Fr. *Ultramarin*, G.—This fine blue pigment was formerly obtained from *lapis lazuli*, or *lazulite*, a mineral of Siberia. It is now prepared artificially on a very large scale. In preparing it, a mixture of soft clay with sodium sulphate, charcoal, caustic soda and sulphur is heated in crucibles. In this way a colorless compound is first produced, termed white ultramarine. This, however, soon becomes of a green color. The green ultramarine thus obtained, which is also used as a color, is then mixed with sulphur and heated. The sulphur takes fire and is allowed to burn in the air, when the product becomes of a fine blue color. (*Roscoe and Schlorlemmer*, vol. ii, 459.) It is thought to be a compound of aluminum and sodium silicates with sodium polysulphide, although the sulphur present is retained in two conditions, part being deposited when ultramarine is treated with acids and part escaping as hydrogen sulphide.

Umbellularia. *Umbellularia californica* (Arn.) Nutt. *California Laurel. California Sassafras. Spice Tree.* (Fam. *Lauraceæ.*)—This is a handsome, evergreen shade tree of California, up to 90 feet in height with alternate, lanceolate, aromatic leaves, axillary umbels of small greenish flowers and purple drupes. The leaves are employed in *neuralgic headaches*, and in *intestinal colic* and *atonic diarrhea;* also externally as a mild counterirritant. Stillman and O'Neill (*N. R.*, 1883) obtained from the seeds a new acid, *umbellulic acid.* The leaves are said also to contain about 4 per cent. of a volatile oil, having a specific gravity of 0.936, a warm camphoraceous taste, and a strong pungent odor. Burse has separated from the oil by fractional distillation *umbillol*, an oil having the formula $C_8H_{12}O$, which dissolves in concentrated sulphuric acid with red color, and is narcotic. (*Ap. Ztg.*, xi.) According to Schimmel & Co. (*Schim. Rep.*, April, 1897), it also contained cineol. It is probable that the volatile oil is a strong local anesthetic, as it has been found to act rapidly when brought in contact with exposed pulp or sensitive dentine. The fluidextract has been used in *doses* of from ten to thirty minims (0.6–1.8 cc.).

Umber. *Terra Umbra.*—A mineral of a fine compact texture, light, dry to the touch, shining when rubbed by the nail, and of a fine pale brown color, which changes to a peculiar beautiful deep brown by heat. According to Klaproth, it contains 13 parts of silica, 5 of alumina, 48 of ferric oxide, 20 of manganese, and 14 of water in 100. *Burnt umber*, as well as the mineral in its unaltered state, is used in painting. The umber of commerce is said to be brought chiefly from the island of Cyprus.

Uranium. $U = 238.5$.—A heavy metal of the radium group, sp. gr. 18.68 melting point 800° C. The salts of uranium are obtained from the mineral *uraninite* or *pitchblende*, which is noteworthy from the fact that it is the mineral in which Becquerel discovered radio-active properties in 1896, which led to further investigation and the subsequent discovery of radium by the Curies about four years later (see *Radium*). Pitchblende consists of mixed oxides of uranium and has the formula $UO_2.2UO_3$. The salts of uranium are really not true salts of the element but are compounds of the lower oxide UO_2, and are usually called uranyl salts. Upon treating solutions of these uranyl salts with sodium hydroxide solution a yellow precipitate of sodium uranate $Na_2U_2O_7$ is produced which is of technical use in producing a variety of glass, with a peculiar yellow fluorescence, known as uranium glass. The salts of the metal uranium are violent poisons, producing not only severe *gastro-enteritis* and *nephritis*, but also acting specifically on the hemoglobin of the blood, affecting its oxygenating powers. (See *P. J.*, Sept., 1890; Oct. 30, 1897.) They have been carefully investigated by Jacob Woroschilsky (*Arbeiten d. Pharm. Inst.*, Dorpat, v, 1890), who finds that they are violent poisons, though acting slowly, especially when given subcutaneously, small toxic doses producing death almost as rapidly as larger ones. In the lower animals, 1 milligramme of the oxide per kilogramme will produce an intense parenchymatous nephritis, followed by violent inflammation of the intestines. There is marked elevation of the blood pressure and widspread degeneration of the tissues, especially of the blood vessels. In mild cases of poisoning a transient glycosuria is a primary symptom.

Uranium calcium phosphate, according to Churchward (*L. L.*, 1911, i, p. 660), is radioactive and may be used instead of radium in the treatment of *rodent ulcers*.

Jackson (*A. J. Phys.*, 1910, xxvi, p. 381) finds that *sodium-uranium tartrate* causes a slight rise in the blood pressure and some increase in the respiration; it destroys the coagulability of the blood, but does not affect its oxygen carrying power.

Uranium Nitrate. *Uranii Nitras, U. S. IX. Uranyl Nitrate.* $UO_2(NO_3)_2 + 6H_20 = 502.62$.—Uranium nitrate was dismissed at the tenth revision of the U. S. P. It was formerly described as follows: "Uranium Nitrate occurs in the form of light yellow prisms; odorless and having a bitter, astringent taste; somewhat efflorescent; radioactive. One Gm. of Uranium Nitrate dissolves in 1.2 mils of water at 25° C.; freely soluble in alcohol or ether. Aqueous solutions of Uranium Nitrate are yellow and acid to litmus. Separate portions of an aqueous solution of the salt (1 in 20) yield, with sodium hydroxide T.S. or ammonia water, a yellow precipitate insoluble in an excess of the reagent but soluble in ammonium carbonate T.S.; with ammonium sulphide T.S. a dark brown precipitate; and with sodium phosphate T.S. a yellow precipitate. Mix 2 mils of the aqueous solution with an equal volume of sulphuric acid, cool the mixture, and add a crystal of ferrous sulphate; a dark brown color appears around the crystal. An aqueous solution of the salt does not respond to the Test for heavy metals (see Part III). An aqueous solution of the salt (1 in 20) remains clear after the addition of an equal volume of ammonium carbonate T.S. (*alkaline earths*). Dilute 3 mils of this mixture to 10 mils with distilled water and add 10 mils of hydrogen sulphide T.S.; no color or precipitate is produced (*iron, manganese*, or *zinc*). A solution of 1 Gm. of Uranium Nitrate in 20 mils of distilled water, acidulated with 1 mil of diluted sulphuric acid, does not completely decolorize 0.1 mil of tenth-normal potassium permanganate V.S. (*uranous compounds*). An aqueous solution of the salt (1 in 100) does not at once produce a turbidity with barium chloride T.S. (*Sulphate*).

"*Assay.*—Dissolve about 0.4 Gm. of the salt, accurately weighed, in 100 mils of distilled water, heat the solution to boiling, add ammonia water until no further precipitate is produced, and allow the precipitate to settle. Then wash the precipitate well on a filter with an aqueous solution of ammonium nitrate (1 in 100), and afterwards moderately ignite it in a platinum crucible, with free access of air, until the weight is constant. The urano-uranic oxide (U_3O_8) so obtained corresponds to not less than 54.8 per cent. of the weight of the salt taken, which is equivalent to not less than 98 per cent. of $UO_2(NO_3)_2 + 6H_2O$." *U. S. IX.*

Uranium nitrate has been used in the treatment of *diabetes mellitus.* There is, however, no sufficient reason to believe that it can influence the metabolism and any diminution which has followed its exhibition may be attributed to injury to the kidney. It is used as an indicator in the estimation of the urinary phosphates, as well as for other chemical purposes. It is incompatible with the alkaloids, chloral hydrate, salts of arsenous and phosphoric acids and changes the color of cochineal and its derivatives.

Dose, from one to two grains (0.065 to 0.13 Gm.).

Urasol. *Acetyl-methylene-disalicylic Acid. Afsal.*

$CH_2(C_6H_3\left\langle{OC_2H_3O \atop COOH}\right.)_2$.—This substance is said to be formed from about 75 per cent. of salicylic acid, 16 per cent. of acetic acid, and 8 per cent. of formaldehyde. It occurs as a yellowish-white powder, insoluble in water, soluble in ether and alcohol, and is incompatible with acids and with iron compounds. It has been used in *doses* of five to eight grains (0.32–0.5 Gm.), given in capsules, in *muscular rheumatism,* irregular *gout,* and as an antiseptic in *cystitis* and other inflammations of the genito-urinary tract.

Urea. *N. N. R.* 1924. *Carbamide. Urée,* Fr. *Harnstoff,* G. $CO(NH_2)_2$.—For an account of the physical and chemical properties of urea, the reader is referred to treatises upon physiology. Urea has been employed in practical medicine as a hydragogue diuretic in the treatment of *dropsies* and as a tonic alterative in *phthisis.* (*L. L.,* December, 1901.) *Dose,* ten grains (0.65 Gm.) every six hours; increase *pro re nata.* Urea is incompatible with chloral hydrate and lead acetate.

Thio-urea is a substance in which one atom of oxygen in a molecule of urea is replaced by an atom of sulphur,

$CS\left\langle{NH_2 \atop NH_2}\right.$ or C_4N_2S. According to Paul Binet (*Rev. Méd. de la Suisse Rom.,* 1893), it is a very active poison, paralyzing the nerve centers, but leaving intact the peripheral nerves and the muscles. It is used commercially as a photo fixing agent and to remove stains from negatives.

Ureabromine. *Bromo-calcium Urea.* $CaBr_2 \cdot 4CO(NH_2)_2$.—This occurs as colorless, odorless crystals, freely soluble in both water and alcohol, with a melting point of 186° C. and representing 36 per cent. of bromine. It is incompatible with chloral hydrate, potassium iodide and acids. It has been used by Fischer and Hoppe (*B. K. W.,* 1911) with asserted remarkable results in spasmodic conditions of children, especially in *epilepsy.* He attributes this effect not only to the bromine, but also to the readily absorbable calcium it contains. The *dose* for the adult is from thirty to sixty grains (2–4 Gm.).

Urechites. *Urechites suberecta* Muell. *Savannah Flower. Yellow-flowered Nightshade.* (Fam. *Apocynaceæ.*)—This is a woody plant with ovate leaves and yellow flowers, indigenous to Colombia. It grows abundantly in the West Indian Islands and to some extent in Florida. It is said to be used in Jamaica by the negroes as a poison. The symptoms which it produces are violent vomiting and purging, with convulsions. J. J. Bowrey (*J. Chem. S.,* June, 1878) has isolated from it two glucosides, *urechitin* and *urechitoxin,* having respectively the formula $C_{28}H_{42}O_8$ and $C_{13}H_{20}O_5$. Isaac Ott (*T. G.,* 1880) finds the plant to be a powerful cardiac poison, first increasing and then depressing the arterial pressure, and finally, if the dose be large enough, killing by producing cardiac arrest. The results reached by Ott are in accord with those of Ralph Stockman (*Laborat. Rep., Royal College of Physicians,* Edinburgh, vol. iv, 1892), who finds that both of the glucosides are very active poisons belonging to the digitalis group. On the other hand, Vowinkie came to the conclusion that even small doses of the plant depress the heart, and experiments made upon man by Bowrey show that in large doses the drug produces nausea, vomiting, general depression, great perspiration, and slight swelling of the pulse. Stockman (*Rev. de Clin. et de Thér.,* June 29, 1892) found that the leaves contain a toxic alkaloid, which he calls *urechitine,* $C_{28}H_{42}O_8 + H_2O$, and a glucoside, *urechitonin,* which is less toxic. In Jamaica the drug is said to have been used in the treatment of *intermittent* and other *sthenic fevers.* The *dose* of the fluidextract is from two to ten minims (0.12–0.6 cc.).

Uretrol. *Sodium Dimethylaminoazobenzene Meta-sulphonate.* $C_6H_5N = NC_6H_3N(CH_3)_2CH_2 \cdot SO_3Na$.—This substance is asserted to be the product of the reaction of dimethyl amidoazobenzene with formaldehyde and sodium bi-sulphite. It occurs in orange-yellow crystals, melting at 113° C. It is said to be actively antiseptic and non-irritant. It has been used by Italian physicians as an injection in urethritis.

Ursal.—A compound of urea and salicylic acid, used as a substitute for sodium salicylate for the treatment of *rheumatism* in doses of ten to thirty grains (0.6–2.0 Gm.).

Urtica. *Nettle. Ortie brûlante,* Fr. *Brennessel,* G.—Various species of this genus (Fam. *Urticaceæ*) are furnished with poisonous stinging hairs. *Urtica gigas* A. Cunn (now *Laportea gigas* Wedd.), of Eastern Australia is said frequently to kill horses, and to produce in man a sting whose impression lasts for months. (*N. R.,* 1875.) Stinging hairs are known to occur in the following genera of *Urticaceæ: Urtica, Laportea, Hesperocnide, Fleurya, Urera, Girardinia,* and *Scepocarpus.* Under the microscopic those of *Urtica* and *Laportea* are long, conical and unicellular, the apex bearing a small spherical or ovoid head which is attached obliquely and readily breaks off upon contact, when the irritating fluid contents are discharged. It has generally been thought that the virulence of the hairs is due to the presence of free formic acid (*A. J. P.,* xxii), and David Hooper (*P. J.,* April, 1887) has demonstrated the presence of formic acid, or a substance very closely allied to it, in the hairs of the *Nilgri nettle* (*Girardinia palmata* Gaudich.). Nevertheless, it does not seem probable that formic acid is the poison. G. Haberlandt believes it to be a non-volatile albuminoid, and L. Reuter has obtained from several nettles a glucoside. (*A. J. P.,* Jan., 1890.) Oddi and Lomonaco (*Rif. Med.,* April, 1892) isolated from the common nettle a crystalline alkaloid, and found that in mammals the extract acts powerfully upon the vasomotor system, and in frogs causes centric paralysis with diastolic cardiac arrest.

U. dioica L., or *common nettle,* and *U. urens* L., or *dwarf nettle,* European plants naturalized in waste places to some extent in the United States, have been used in medicine as local irritants, as diuretics (*A. J. P.*, 1866), and especially for the purpose of arresting *uterine hemorrhage.* The fluidextract may be given in *doses* of half a fluidrachm (1.8 cc.) or a decoction of the strength of an ounce to a pint in teacupful doses. Under the name of *brandol* is marketed a preparation used in the treatment of *burns* and *wounds;* it is a liquid consisting of 93 per cent. infusion of urtica, 2 per cent. picric acid and 5 per cent. glycerin.

Ustilago. *U. S.* 1880. *Corn Smut.*—The genus *Ustilago* belongs to the *Ustilaginaceæ,* a family of protobasidiomycete fungi whose members are parasites living in their vegetative (mycelial) stage, within the intercellular spaces of the host and frequently developing haustoria which penetrate the host-cells and absorb nutriment from them. Their conspicuous reproductive stage is usually evident as spore masses upon the flowers but occasionally on other parts of the host plant. Each spore mass first appears as a shiny tumor that later matures to form a sooty mass of spores. They produce the *smut* in cereals. *Ustilago Maydis* (DC.) Tul. is produced on the stems, the pistils (corn grains), and the male inflorescence (tassel) of the Indian corn. It is specifically characterized by its minute spheroidal spores, averagely 7 to 10 microns in diameter, the outer walls of which are marked with blunt echinulations. It is abundant in the United States. Upon the corn the smut appears in masses, varying in size from a cherry to a child's head. These masses are smooth, irregularly globose, or sometimes lobulated, having at first a livid, bluish tint, and then becoming blackish, and finally bursting and emitting the black contents, consisting of innumerable globose very minute spores, each of which is covered with beautiful little pointed processes. In a dried state the masses are blackish and covered with a black powder.

C. H. Cressler found in ustilago an alleged alkaloid, *secaline,* besides a thick, viscid, fixed oil and a resin soluble in ether, but not in alcohol. (*A. J. P.*, 1861, 306.) Rademaker and Fischer (*Nat. Drug.*, 1887, 296) believed that they had discovered a white, bitter alkaloid, *ustilagine,* soluble in ether, while H. B. Parsons decided that the fixed oil contained an acid which he provisionally named *sclerotic acid;* also an amine-like volatile substance extracted by ether. (*N. R.*, March, 1882; also *West. Drug.*, 1894.) A. W. Balch (*Journ. Boston Soc. Med. Sci.*, March, 1901) was not able to find any active substance in the smut.

The belief that corn smut is an abortifacient to the lower animals (*A. J. P.*, Sept., 1861) appears to be without foundation, as in the experiments made by the United States Department of Agriculture in 1898 (*Farmers' Bulletin*, No. 69) no effect was produced by corn smut given to pregnant cows. The experiments of James Mitchell (*T. G.*, ii, 223) that ustilago abolishes sensation, reflex action, and later general motor power in the frog, is contradicted by the results of Balch, who also found that enormous doses of the substance have no effect upon the color of the cock's comb. In *doses* of one to two drachms (3.9–7.7 Gm.) it has been claimed by W. A. N. Dorland that the fluidextract markedly increases the severity and frequency of the uterine pains in human labor. The whole drift of our present evidence is to show that ustilago is probably inert.

Uzara. *Uzaron.*—Under this name the root of an undetermined African plant, probably belonging to the *Asclepiadaceæ,* has been used both by the natives and European physicians in the treatment of *dysentery,* especially of the amebic variety. Guerber and Frey (*A. E. P. P.*, 1913, lxxv, p. 75) have determined that it contains neither alkaloid nor tannin, but does contain non-nitrogenous glucosides which have a digitalis-like action upon the heart and diminish peristalsis of the intestines. It appears to owe its virtues in part to its amebicidal action, but in part also to its effect upon the intestinal muscles.

Vaccines. *Bacterins.*—Efficient vaccine therapy is much older than serum therapy. The word vaccine takes its origin from the Latin *vacca,* cow, and Jenner's publication of 1798, "*An Inquiry into the Causes and Effects of Variola Vaccinæ.*" (See Part I, *Virus Vaccinicum,* U. S. *Vaccine Virus,* p. 1203.) Vaccination against smallpox is still our most reliable method of immunization against an infectious disease. Pasteur later applied the term vaccine to his attenuated anthrax virus, and Sir Almroth Wright has still further extended it in his "*bacterial vaccines*" to cover killed cultures of micro-organisms injected into man for the cure as well as the prevention of disease. Strictly, vaccine should mean only one thing, the virus of vaccinia or cow pox.

The various products treated below have this in common, that they are disease producers so modified as to be comparatively harmless, and are used to immunize against the disease which in their virulent form they cause.

This immunization may be either to prevent infection or to ameliorate, or cure, an already existing infection. Vaccines, then, are classed as *antigens,* while serums represent *antibodies.* In receiving a vaccine, the patient is called upon to manufacture his own antibodies. This fact is not to be lost sight of, particularly in serious illness. By vaccine treatment there is being introduced into the body material more or less similar to those invaders which the body forces are already striving to overcome. The balance in the struggle may be a narrow one, and such a load, though well intended, may turn the battle in the wrong direction. On the other hand, for preventive immunization, vaccine therapy has the advantage that the antibodies produced in the patient's own serum are more stable than when introduced in foreign serum and, furthermore, that the cells of the body as well as the blood fluid may be brought into the defensive line.

The greater part of these vaccines are bacterial vaccines. These are suspensions of killed bacteria in physiological saline solution, with 0.25 to 0.5 per cent. phenol or cresol as preservative. The bacteria are usually grown on a solid medium, such as agar, are washed off with the saline solution, and the killing is usually accomplished by heating one hour at 53° to 60° C., though strong antiseptics may be used for this purpose.

The number of organisms per cc. is estimated by direct counting in a microscopic chamber, by comparison with the number of blood cells in normal human blood, or by relative density; saline solution is then added to reduce the suspension to the desired strength. When in the final containers tests are made to insure sterility.

"*Stock vaccines*" are prepared from strains of the different organisms carried in stock by the producer. "*Autogenous vaccines*" are made up from the actual cultures obtained from the patient to be treated and are usually preferred (see remarks on specificity, under *Immune Serum.* Nevertheless, on account of the delay and expense of obtaining and isolating the patient's own strain, stock vaccines are often used. For prophylactic immunization, of course, stock vaccines are necessary. Many of the reported instances of benefit from the use of stock vaccines are to be attributed not so much to the formation of specific antibodies, for the organism in consideration as to the general increase in the bodily resistance against bacterial invasion which is brought about by the introduction of a foreign protein. (See *Protein Therapy.*)

Aside from prophylaxis (*typhoid fever, cholera*) the success in bacterial vaccine therapy seems to have been attained in chronic, sluggish, localized infections.

Bacterial vaccines deteriorate with age—how much we are unable to tell until we have a measure of their potency. They should, however, be kept at 4° to 15° C. and be used within a short time—probably three or four months—of their preparation.

Rabies Vaccine. N. N. R. 1917. *Antirabic Virus. Pasteur Treatment.*—The prevention of *hydrophobia* in persons bitten by rabid animals is one of the debts owed by the world to Pasteur. While formerly 15 per cent. of such unfortunate people contracted rabies and died, the mortality now in treated cases is less than 1 per cent. usually and in some institutes almost zero. The treatment is in a sense a preventive one. It is instituted after the bite, but before symptoms have developed. On account of the long incubation period in rabies there is then opportunity to acquire immunity in most cases.

The dried cord method of Pasteur, which is still the most used on account of its long successful history, consists in daily hypodermic injections of portions of the dried spinal cord of rabid rabbits. The rabbits have been inoculated intradurally with "fixed virus," that is, a virus whose incubation period has been shortened and fixed at five to seven days by passage from rabbit to rabbit through a long series. The usual incubation period of "street virus," or rabies as it occurs naturally, is from 12 to 90 days. In this process of fixation the virus gradually loses its virulence for man. The cords of the rabbits are dried for various lengths of time over caustic potash in an aseptic manner; if dried for 6 days, the cord is called a "6-day cord." The treatment is begun with cords dried the longest time; originally Pasteur began with a 14-day cord, but the tendency has been to use cords dried fewer and fewer days, as the fixed virus has been found practically innocuous for man. The treatment lasts about 21 days, a piece of cord 5 millimeters long is emulsified in 2.5 cc. salt solution and injected each time. Other modifications of the Pasteur treatment are the injection of weak dilutions of the fresh fixed virus (Högyes), the carbolization of the virus (Fermi), attenuation by dialysis (Cumming) or by drying while frozen (Harris). The emulsion of the virus should be prepared as few hours as possible before its use.

Acne Bacillus Vaccine. Vaccinum Acne. N. N. R. 1924.—The acne bacillus is a short rod, not decolorized by Gram's stain, growing only in the absence of oxygen, and even sluggishly then. The vaccine prepared from it is used in cases of *acne* in which the bacillus is found and which do not improve under the usual staphylococcus vaccine. The usual *dose* is about 5,000,000 killed bacteria.

Cholera Vaccine. Vaccinum Choleræ. N. N. R. 1924.—The cholera vibrio is the cause of *Asiatic cholera.* It is a curved rod, decolorized by Gram's stain, a rapid grower, and prefers an alkaline medium. Cholera vaccine has given favorable results in India and Japan, and during the World War was used extensively in the Balkans with reduction in the incidence and mortality among the vaccinated.

Gonococcus Vaccine. N. N. R. 1924.—The gonococcus is a thick, coffee-bean shaped organism occurring in pairs. It is decolorized by Gram's stain and is difficult to grow, even on media which contain one of the body fluids. In *gonorrheal urethritis, vaginitis,* and *ophthalmia* no benefit is to be expected from vaccine treatment. There are probably different strains or types of gonococci, and this together with the low antigenic power of the organism may explain the not very satisfactory results with gonococcus vaccine in chronic infections such as *arthritis* and deep urethritis. The *doses* used are 5,000,000 (freshly isolated cultures) to 1,000,000,000 (old strains).

Pertussis Bacillus Vaccine. N. N. R. 1924.—The pertussis bacillus, or bacillus of Bordet-Gengou, is the cause of *whooping-cough.* It is a very small Gram-negative rod, growing at first only on special media. The vaccine prepared from this organism is used both as a preventive and in the treatment of whooping-cough. In the former case three doses of 50,000,000 to 2,000,000,000 are given a week apart. For treatment, the *doses* range from 50,000,000 to 2,000,000,000 every two to four days. It is reported that the vaccine treatment makes the attack milder and in particular shortens the course of the disease. Apparently a freshly prepared vaccine gives better results than an old vaccine. In many institutions for children, the vaccine is given to all new admissions with a claimed reduction in the number of cases developing after admission.

Plague Bacillus Vaccine. Vaccinum Pestis. N. N. R. 1924. *Haffkine Prophylactic.*—The bacillus of *bubonic plague,* or *Bacillus pestis,* is a short, Gram-negative rod which has a tendency to take up the stain more intensely at the ends, leaving a relatively light staining central portion. It grows fairly well on ordinary laboratory media and is one of the most virulent bacteria known, since it will easily cause a fatal infection by mere contact with the abraded skin. The vaccine is used with fair success as a preventive—those inoculated being less prone to the disease than the uninoculated in the same community and having relatively milder attacks if not entirely protected. Though the prophylactic is useful for travellers through badly infected territory, reliance in a plague outbreak is to be placed in eradicative measures rather than in Haffkinization of the population.

Staphylococcus Vaccines. N. N. R. 1924.—There are three species of varieties of staphylococci concerned in human disease, the *Staphylococcus albus,* which produces a white growth on solid media; the *Staphylococcus aureus,* which produces golden yellow, and the *Staphylococcus citreus*, giving a lemon yellow. The first of these is the usual cause of the relatively mild skin pimples and boils; the second is more likely to be encountered in more severe abscesses and carbuncles, while the third is relatively rare. All are large round organisms, Gram positive and tending to a tesselated arrangement; rapid growth is obtained on all ordinary media. It is with these organisms that the most striking successes of vaccine therapy have been made, particularly in *furunculosis*. If possible, the vaccine should be autogenous, but cure is frequent with stock vaccines. Some cases will not respond even to autogenous vaccines. The initial dose should be 500,000 to 1,000,000 and subsequent doses should be increased by 500,000 until a dose of 2,000,000 is reached. The injections should not be given more frequently than 5 days, and usually 6 to 10 injections are advisable. Reactions following the use of staphylococcus vaccine are usually slight. As with other methods of treating this affection, relapses are not infrequent; more intensive and prolonged treatment is then indicated. *Sycosis vulgaris, pustular acne, carbuncles, abscesses* are all amenable to vaccine therapy to a greater or less degree, but, especially in the two latter, surgical measures should not be neglected.

Streptococcus Vaccine. N. N. R. 1924.—There are two general types of streptococci, one known as *Streptococcus hemolyticus*, and the other as *streptococcus non-hemolyticus*, and there are a number of different types or strains in each of these two main divisions. The usual *Streptococcus pyogenes* is a round or oval organism. Gram positive, tending to be arranged in chains, and to divide with the line of division at right angles with the chain; the cocci often appear in pairs. This organism grows less readily and in smaller colonies than the staphylococcus. The streptococci forming long chains (*Streptococcus longus*) are thought to be more pathogenic than those with short chains (*Streptococcus brevis*). On blood agar the colonies have a clear halo, due to hemolysis (*Streptococcus hemolyticus*). Other strains (called *Streptococcus viridans*) produce greenish colonies under like conditions; these latter are found in infections such as *endocarditis* and *arthritis*, while the hemolytic strains occur in the virulent, pyogenic *phlegmons* and fatal *septicemias*. Another form, *Streptococcus mucosus*, produces a mucoid growth, and has a capsule like the pneumococcus.

The name *Streptococcus rheumaticus* is given to the streptococci found in *rheumatism*, *Streptococcus erysipelatus* to those of *erysipelas*. Recent work by Dick and Dick, Dochez and others (see *J. A. M. A.*, 1924, lxxxviii, p. 542, 712, 1246) has apparently proved that *scarlet fever* is caused by a particular strain of the streptococcus of the hemolytic group to which has been given the name of scarlet fever streptococcus. This strain produces a toxin which has been used to produce an antitoxin against scarlet fever. The toxin has been used in the performance of the Dick test to determine susceptibility to scarlet fever in the same way that the Schick test is used for diphtheria.

On account of our inability to treat the greater part of the streptococcal infections directly, this has been a favorite field for vaccine therapy, but the results are far from convincing. Occasional favorable results are obtained in the treatment of one or another conditions of streptococcal invasions, especially if attention is paid to strain specificity and the tendency of the organisms to decrease in pathogenicity and immunizing power under artificial cultivation.

Streptococcus and Prodigiosus Vaccine. N. N. R. 1924. *Toxins of Erysipelas and Prodigiosus. Coley's Fluid.*—This suspension, used in the treatment of inoperable *sarcoma*, is practically a bacterial vaccine prepared from *Streptococcus pyogenes* and *Bacillus prodigiosus*. Due to the latter, the fluid has a reddish tint. An analysis of the reported cases in which it has been used indicates that it is probably of some value in the field for which it is recommended.

Typhoid Bacillus Vaccine. Vaccinum Typhosus. N. N. R. 1924. *Typhoid Vaccine. Typhoid Prophylactic.*—The typhoid bacillus, or *bacillus of Eberth*, is an actively motile rod, sometimes very short, sometimes by the end-to-end arrangement of several individuals, long and filamentous, Gram-negative and growing readily on ordinary media. It is the cause of *typhoid fever*—in German *typhus*, but to be distinguished from true typhus fever, or *typhus exanthematicus*. As the staphylococcus vaccines are the best examples of vaccine therapy, so typhoid vaccine is the best example of prophylaxis by bacterial vaccine. Treatment of *typhoid fever* by vaccines, while yielding some slightly encouraging results, is often dangerous on account of the severity of the general infection. Attempts to rid typhoid carriers of their bacilli by vaccine therapy are occasionally successful, usually not.

In 1896 Pfeiffer and Kolle in Germany and Wright in England began work on typhoid immunization. The German vaccine was grown on solid medium-agar—the English in broth and heated to 60° C. Later Leishman found that heating to 53° to 54° C. was sufficient and gave better immunization. The English used one injection at first, then two, eight days apart. Kolle advised three. The method of the American army, instituted by Russell, followed the agar cultures and the triple dose of Kolle, but used Leishman's strain and temperature. The results in the United States Army are well known and striking; together with improved sanitation, the compulsory vaccination has practically eliminated typhoid. The results from the use of typhoid vaccine both in civil and army practice have been so overwhelmingly favorable that it is not necessary to give statistics of these results. The value of typhoid vaccination is universally recognized and its practice is general. It should be given in a course of three injections seven days apart. A certain number of persons develop a local and sometimes general reaction after taking typhoid vaccine. The reaction is milder and less frequent in young children than in adults.

Reactions both local and febrile are often seen within forty-eight hours, more frequently with some lots of vaccine than with others. The vaccine produces agglutinins (positive Widal test) in men and animals injected, also bacteriotropism or opsonin against the typhoid bacillus. Typhoid vaccine probably becomes more or less inactive after a few months and should be kept at a temperature between 4° and 15° C. in the dark.

The protection given by the vaccine is not absolute nor life-long, but for three years it is usually sufficient to resist all ordinary intensities of infection, and some immunity doubtless persists through life. Even when the vaccinated do chance to contract the disease, their attack is generally much milder than in the unvaccinated. As it has been found that vaccination with the typhoid vaccine does not give protection against infection with the *B. paratyphosus A.* and *B. paratyphosus B.*, practically all typhoid vaccine now used is prepared from the three organisms in the proportion of 1,000,000 of typhoid bacilli and 500,000 each of the two paratyphoids in each cc.

Pollen Extract. N. N. R. 1924. *Hay Fever Vaccine.*—This product is included with the vaccines because it depends on an immunological response on the part of the person receiving treatment. Hay fever and rose cold are probably caused by the irritant action of the pollen of certain plants on the ocular and respiratory mucous membranes of especially sensitive individuals. By skin inoculation it is often possible to determine to what pollens a person is sensitive. The administration of pollen extract is an attempt to decrease their sensitiveness, in other words, to immunize the patient against the pollen. The Gramineæ or grasses are chiefly concerned in the production of rose cold (June cold), and the Compositæ in that of *hay fever* or autumnal catarrh. Pollen extracts have been prepared from each of these two great classes and favorable reports from treatment are not uncommon. The extract is usually given in a long series of injections, preferably before the symptoms of the year appear. The extract is unstable and should be used when freshly prepared. Severe reactions may also occur with potent extract unless the symptoms are watched and the increase in dosage made gradually.

Vaccinium. *Vaccinium crassifolium* Andr. *Blueberry.* (Fam. *Vacciniaceæ.*)—The leaves of this slender trailing shrub, found growing in sandy most pine woods from North Carolina to Georgia, are said to be astringent and diuretic, and capable of replacing uva ursi. *Dose*, of the fluidextract, from a half to one fluidrachm (1.8–3.75 cc.).

Valeric Acid. *Valerianic Acid. Acidum Valericum. Acidum Valerianicum. U. S.*, 1870. *Isopropylacetic Acid. Acide valérique*, Fr. *Valeriansäure, Baldriansäure*, G. *Acido valerianico*, It., Sp. $HC_5H_9O_2$. Mol. wt., 102.08.

Valeric acid (originally valerianic acid) received its name from having been found in the oil distilled from valerian. It was first obtained in 1817 by Chevreul from the oil of the dolphin, and received the name of *delphinic acid*, which, however, upon the discovery of its identity with the acid afterwards obtained by Pentz from valerian, was superseded by its present title. It has been obtained also from the bark and fruit of *Viburnum Opulus* L. and other species of *Viburnum* (Fam. *Caprifoliaceæ*), the sap wood of the European elder (*Sambucus nigra* L.) (Fam. *Caprifoliaceæ*), the root of *Angelica Archangelica* L. (*Archangelica officinalis* Hoffm.) (Fam. *Umbelliferæ*), and from various organic products of the vegetable and animal kingdom. At present it is chiefly made synthetically from amyl alcohol.

Valeric acid is a colorless liquid, of an oily consistence, a repulsive odor, resembling that of valerian, and a pungent, sour, acrid, disagreeable taste. Its sp. gr. is 0.955, melting point 36° C., boiling point 177° C. It is soluble in thirty parts of cold water. Alcohol and ether mix with it in all proportions. It is very soluble in strong acetic acid and dissolves camphor and some resins. It forms salts with the alkalies and reddens litmus paper strongly, but the blue color gradually returns in a warm place. For tests of purity by Mossler, see *P. J.*, 1911, 175.

The virtues of valerian have been attributed to valeric acid and the latter has therefore been used as a nerve sedative, but it is probably inert. The customary *dose* is from three to ten minims (0.2–0.6 cc.).

Valeridin. *Valerydin. Sedatin. Iso-valeryl-p-phenetidin.* $C_6H_4\left\{\begin{matrix}NHCOC_4H_9\\OC_2H_5\end{matrix}\right.$.—This substance occurs as white, glistening needles, which are readily soluble in alcohol or chloroform, difficultly soluble in ether, and almost insoluble in water. It is obtained by heating isovaleric acid with p-phenetidin. C. Erdmann (*Ph. Ztg.*, xliii) commends this substance in *doses* of from eight to fifteen grains (0.5–1.0 Gm.) a day, as a succedaneum for valeric acid, and as being serviceable in *migraine, neuralgia* and *hysteria.*

Validol. *Menthyl Valerate.* $CH_3.CH_2.CH_2.COO.(C_{10}H_{19})$.—*Validol* is a clear, colorless liquid, of a mild, pleasant odor, and slightly bitter taste, said to contain 30 per cent. of menthol combined chemically with 70 per cent. of valeric acid. It was originally proposed by Schwersenski (*Th. M.*, 1897) as being locally non-irritant and affording a means of exhibiting menthol for its local action in *pruritus, gastralgia, coryza,* various mucous inflammations, and as an antispasmodic in *migraine, neurasthenia, hysteria* and other neuroses. Validol has also been used as an antemetic, for the relief of *sea-sickness* and in other forms of *nausea.* It is stated to be specially eliminated through the urine, to which it imparts a peculiar odor. *Dose,* five to twenty minims (0.3–1.3 cc.); locally 10 to 15 per cent. ointment is recommended.

Validolum Camphoratum is a 10 per cent. solution of camphor in validol.

Valonia. *Acorn Cups. Valloné, Vélanède, Gallon,* Fr. *Knoppern, Walonen,* G.—The great cups of the acorns of the *Quercus Aegilops* L. (Fam. *Cupuliferæ*), an evergreen tree, native to Bosnia, contain a very large percentage of tannin. They are extensively exported for dyeing and tanning, and have been employed as an astringent in *diarrhea.*

Valyl. *Valeric Acid Diethylamide,* $C_4H_9.CO.N(C_2H_5)_2$.—It occurs as a colorless liquid having a characteristic odor and burning taste, and boiling at 210° C. According to Kionka (*D. M. W.*, xxvii, 1901), valyl produces cerebral excitement, attended with convulsions, probably of cerebral origin, as there is no increased reflex activity. It is said primarily to increase the blood pressure and to have little action upon the heart or respiration. It is somewhat irritant, but may be given in four per cent. aqueous solution, and has been used as a substitute for valerian in *hysterical* and allied *neuroses. Dose,* four to fifteen grains (0.26–1.0 Gm.) three times a day, preferably administered with an equal amount of tallow in gelatin capsules.

Vanadic Acid. *Acidum Vanadicum. Metavanadic Acid.* HVO_3.—Forms golden-yellow scales, which are only slightly soluble. According to Le Blond and C. David, *vanadic acid* is actively antiseptic, and very useful in solutions for the skin, 0.05 in 1000; for gynecological use, 0.17 in 1000.

The meta-vanadates are used in preference to the ortho, pyro, etc., due to their stability in solutions. They are incompatible with acids, the latter imparting to their solutions a yellowish-red color.

In the arts vanadic acid is used in various oxidizing processes as a carrier of oxygen, effecting by its presence the more efficient action of other oxidants, as in the aniline black formation, where a small amount of ammonium vanadate is capable of taking the place of large amounts of chlorates and similar oxidizing agents. It is also used in vanadium inks.

The vanadium compounds are prepared from the element *vanadium,* a light gray crystalline metal. The principal source of vanadium is the mineral natronite, an impure vanadium sulphide mined in Peru. The element is used in iron alloys to give hardness.

According to Jackson (*J. P. Ex. T.*, 1912, iv, p. 1) *sodium orthovanadate,* when injected in large doses, produces a slight rise in the general blood pressure, which is due to constriction of the vessels of the abdominal region, increased peristalis of the intestinal tract, salivation, vomiting and diarrhea, more or less spasm of the bronchial muscles, and death from respiratory failure.

According to Dutton (*J. A. M. A.*, June 3, 1911), workers in industries in which vanadium is used, suffer from a form of chronic poisoning, the most important results of which are congestion of the lungs and of the kidneys, and sometimes hemorrhagic nephritis and also irritation of the gastro-intestinal tract. Anemia is an early symptom, and there is usually a dry cough, loss of appetite, emancipation and albuminuria.

The vanadates have been used in *anemia, tuberculosis* and a host of other chronic diseases, but are probably without therapeutic virtue. The usual *dose* of *sodium* or *lithium metavanadate* is from one-sixtieth to one-fifteenth of a grain (0.001–0.004 Gm.).

Under various names, as *vanadiol, oxylasine,* etc., various proprietary preparations containing vanadium have been introduced for which extraordinary therapeutic properties were claimed. The evidence in support of these claims, however, is extremely unsatisfactory.

Verbena. *N. F. IV. Blue Vervain.*—"The dried overground portion of *Verbena hastata* Linné (Fam. *Verbenaceæ*), collected when flowering." The plant is a tall shrub growing in damp situations throughout the United States. "In broken or cut pieces; stem stout, obtusely quadrangular, rough, pubescent; leaves opposite, petioles from 12 to 25 mm. in length, blades from 6 to 12 cm. in length, lanceolate, acuminate, acute, coarsely and sharply serrate or the lower hastate lobed, deep green above, paler beneath, conspicuously veined; flowers in terminal interrupted panicles of spikes, spikes erect cylindraceous, densely flowered, each flower subtended by a lanceolate acute bract; calyx adherent, little more than half the length of the corolla, tubular, five-lobed, the mouth slightly oblique; corolla small, bright blue, salver-form tube externally pubescent, subequally five-lobed; stamens adnate to the corolla tube, included, didynamous, fruit dividing at maturity into four one-seeded parts. Odor heavy, especially if dampened; taste bitter and disagreeable. Verbena yields not more than 10 per cent. of ash." *N. F. IV.* The *fluidextract of verbena* was official in the N. F. IV. There is no reason to suspect it of medicinal virtue. The *dose* is fifteen minims (1 cc.).

Verditer.—Two compounds of copper, employed as pigments, are known by this name in commerce, and are distinguished by the epithets of blue and green. *Blue verditer* is a blue *cupric carbonate,* $2CnCO_3Cn(OH)_2$. *Green verditer* is a green cupric carbonate, $CnCO_3Cn(OH)_2$, also known by the names *Bremen green, Brunswick green, mountain green* and *artificial malachite green.*

Vernonia. *Vernonia anthelmintica* Willd. (Fam. *Compositæ.*)—This is an East Indian plant, whose black, bitter, and nauseous seeds have a high reputation in Ceylon as an anthelmintic in *doses* of sixty grains (3.9 Gm.). (*P. J.*, April, 1883; also *Ph. Rev.*, 1896, 274.)

Veronica. *Veronica officinalis* L. *Speedwell. Veronique mâle,* Fr. *Ehrenpreis,* G. (Fam. *Scrophulariaceæ.*)—Several species of *veronica,* common to Europe and this country, have been medicinally employed. Of these, *V. officinalis* L., and *V. Beccabunga* L., or European *brooklime,* are the most conspicuous. *V. officinalis* has a bitterish, warm, and somewhat astringent taste.

Vintilesco found a glucoside in *V. officinalis* and *V. Chamædrys* L. (*J. P. C.*, 1910, No. 4.) The plant has been considered diaphoretic, diuretic, expectorant, tonic, etc., and was formerly employed in *pectoral* and *nephritic complaints, hemorrhages, diseases of the skin,* and in the treatment of *wounds. V. Beccabunga* was used in the fresh state in *scurvy.*

Vieirine.—This substance is obtained from the bark of the *Remijia Vellozii* DC. (Fam. *Rubiaceæ*), of Brazil. It is used in Brazil in *doses* of from one to four grains (0.065–0.26 Gm.) repeated *pro re nata,* as a tonic and as an antiperiodic in place of quinine.

Vilca Bark.—The bark of *Piptadenia macrocarpa* Benth. (Fam. *Leguminosæ*), a timber tree indigenous to Bolivia and adjacent parts of South America which is characterized by its warty bark, bipinnate leaves, mimasaceous flowers and pod-fruits. The natives of Bolivia are said by Rusby to make an aqueous extract from this bark which is added to cane juice to hasten fermentation, the process resulting in an increased yield of sugar. According to Fanchon Hart (*J. A. Ph. A.*, 1922, p. 906) who has first described the structure of the drug, it contains a large percentage of tannin, resin and calcium oxalate.

Vinca.—Under this name are included *V. major* L., *Greater Periwinkle,* and *V. minor* L., *Lesser Periwinkle* (Fam. *Apocynaceæ*). It was, at one time, used in arresting *menorrhagic* and other *hemorrhages.* (*A. J. P.*, 1872.)

Vincetoxicum. *V. officinale* Moench. (now more properly *Cynanchum Vincetoxicum* (L.) Pers. *White Swallow-wort. Vincetoxicum. Asclépiade, Dompte-venin, Hirundinaire,* Fr. *Schwalbenwurz, Giftwende,* G. (Fam. *Asclepiadaceæ.*)—A perennial, herbaceous European plant, the root of which was formerly esteemed a counterpoison, and hence the botanical name. It has a bitterish, acrid taste, and, when fresh, a disagreeable odor, which is diminished by drying. Kubler found a glucoside, *vincetoxin,* $C_{50}H_{82}O_{20}$, which he states differs from *condurangin* which other investigators asserted to be identical. (*A. Pharm.*, 1908, 659.) Taken internally, especially in the recent state, it excites vomiting, and is capable, in larger quantities, of producing dangerous, if not fatal, inflammation of the stomach. Feneulle found in the root a principle analogous to emetine. It has been used in *skin diseases* and *scrofula.*

Vinegar. *Acetum.*—*Vinegar* is produced by the acetous fermentation in infusion of mixed malted and unmalted grain, or of various fruit juices. Any substance which is capable of undergoing the alcohol fermentation is further liable under the influence of a microscopic plant, *Mycoderma aceti*, first described by Pasteur, and exposure to the air at a temperature between 24° C. and 35° C., to undergo further change with oxidation, which converts the alcohol into acetic acid. Practically for success there should not be more than 12 per cent. of alcohol in the original fluid. There are a number of other organisms which oxidize alcohol into acetic acid, viz., *Bacterium aceti*, *B. Pasteurianum*, *B. Kuetzingianum*, *B. Oxydans*, and *B. Industrium*.

In the quick *German process* for making vinegar a mixture of one part of 80 per cent. alcohol, four or six parts of water, and one-thousandth of honey or extract of malt, at a temperature of 24° C. to 35° C., is allowed to percolate through beech shavings, previously steeped in vinegar, and contained in a deep oaken tub, in which is a wooden diaphragm perforated with numerous small holes, loosely filled with packthread about six inches long. It is essential to the success of the process that a current of air shall pass through the tub. In order to establish this current, eight equidistant holes are pierced near the bottom of the tub, forming a horizontal row, and four glass tubes are inserted vertically in the diaphragm, of sufficient length to project above and below it. The air enters by the holes below, and passes out by the tubes. Although the air is necessary for the furnishing of oxygen, acetification consisting chiefly in the oxidation of the alcohol, the beech shavings and similar articles chiefly aid in the process by affording surface upon which the mycoderms can grow. During the process the temperature rises to 37° C. or 40° C., and remains nearly stationary while the process is going on favorably. The liquid is drawn off by a discharge pipe near the bottom, and must be passed three or four times through the tub before the acetification is completed, which generally occupies from twenty-four to thirty-six hours. According to Wimmer, pieces of purified charcoal, about the size of a walnut, may be advantageously substituted for the beech shavings in the process.

In 1862, Pasteur substituted for the German process the sowing of the mycoderm upon the surface of a mixture of wine and vinegar, or of water, alcohol (2 per cent.), and acetic acid (1 per cent.) adding alcohol daily in small quantities after about half that contained in the original liquid had been converted into acetic acid, until a vinegar of sufficient strength was produced. The *French process* was improved in 1869 by Laugier, and it was subsequently further elaborated by Emanuel Wurm. (For details, see *P. J.*, xi, 133.)

In England, vinegar is made from the infusion of malt. The fermented wort is caused to fall in a shower upon a mass of fagots of birch twigs occupying the upper part of a large vat, and, after trickling down to the bottom, is pumped up repeatedly to the top, to be again allowed to fall, until the acetification is completed. This mode of oxidizing the alcohol in the fermented wort has the advantage of rendering insoluble certain glutinous and albuminous principles, which, if not removed, would cause a muddiness in the vinegar and make it liable to spoil.

In the United States, vinegar is largely made by the German method of oxidizing very diluted alcohol, and is called *white vinegar;* it is often prepared from cider—*cider vinegar.* The cider is placed in barrels (with their bung holes open) which are exposed during the summer to the heat of the sun. The acetification is completed in the course of about two years. The process of the fermentation, however, must be watched, and as soon as perfect vinegar is formed, it should be racked off into clean barrels. Without this precaution, the acetous fermentation would run into the putrefactive, and the vinegar spoil. Cider vinegar contains no aldehyde. It contains malic acid, and therefore yields a precipitate with lead acetate. The absence of such a precipitate indicates that the alleged cider vinegar is a manufactured substitute, although a fictitious article might yield a similar precipitate.

Cider or apple vinegar is also made by the quick process described above. Much commercial vinegar is made from the apple cores, skins and other waste from the dried apple and pectin industry. Vinegar may be clarified, without impairing its aroma, by throwing about a tumblerful of boiling milk into from fifty to sixty gallons of the liquid, and stirring the mixture. This operation also makes red vinegar pale.

The series of changes which occur during the *acetous fermentation* is called acetification. The following equations represent this change:

$$C_2H_6O + O = C_2H_4O + H_2O$$
$$C_2H_4O + O = C_2H_4O_2$$

Vinegar, when good, is of an agreeable, penetrating odor, and a pleasant acid taste. According to Magnes-Lahens, wine vinegar always contains a little aldehyde. The better sorts of vinegar have a grateful aroma, probably due to the presence of an ethereal substance, perhaps acetic ether. The color of vinegar varies from water white to deep red. When long kept, especially if exposed to the air, it becomes ropy, acquires an unpleasant odor, putrefies, and loses its acidity.

The essential ingredients of vinegar are acetic acid and water; but, besides these, it contains various other substances, derived from the particular vinous liquor from which it may have been prepared.

Malt Vinegar (*Acetum Britannicum*) has a brown color, and a sp. gr. from 1.006 to 1.019. The strongest kind, called *proof vinegar,* contains from 4.6 to 5 per cent. of acetic acid. That of British manufacture usualy contains sulphuric acid, which the manufacturer is allowed by law to add in a proportion not exceeding one part in a thousand; but if the vinegar be properly made it does not require to be thus protected.

Malt Vinegar is "a liquid of a brown color and peculiar odor. Specific gravity 1.017 to 1.019. 445.4 grains by weight (1 fluidounce) of it require about 402 grain-measures of the volumetric solution of soda for their neutralization, corresponding to 5.41 per cent. of real acetic acid, $HC_2H_3O_2$. If ten minims of solution of barium chloride be added to a fluidounce of the vinegar, and the precipitate, if any, be separated by filtration, a further addition of the test should give no precipitate. Sulphuretted hydrogen causes no change of color." *Br.*, 1885.

Wine Vinegar (*Acetum Gallicum*) is nearly one-sixth stronger than pure malt vinegar. It is of two sorts, the white and the red, according as it has been prepared from white or from red wine. *White wine vinegar* is usually preferred. *Red* *wine vinegar* may be deprived of its color, and rendered limpid, by being passed through animal charcoal. Under the name of wine vinegar or white wine vinegar the so-called distilled vinegar is sometimes sold. This is made, not by distillation of vinegar as the name indicates, but by the distillation of a weak alcoholic liquid produced by the fermentation of molasses with yeast and the subsequent acetification of the weak alcohol by percolation through beechwood shavings impregnated with mycoderma aceti.

The best test for the detection of free inorganic acids is a weak solution of methyl violet which turns green in the presence of free inorganic acids, but remains unaffected by organic acids.

Distilled Vinegar (*Acetum Destillatum; Vinaigre distillé, Oxéolat simple,* Fr.; *Destillirter Essig,* G.) was official in the U. S. Pharmacopœia, 1870, and was prepared by obtaining seven pints of distillate from eight pints of vinegar placed in a glass retort, the one pint left in the retort retaining the fixed impurities, salts, etc. One hundred grains should saturate not less than seven and six-tenths grains of potassium bicarbonate.

The principal foreign substances which vinegar is liable to contain are sulphuric and sulphurous acids, and copper and lead, derived from improper vessels used in its manufacture. Tin has been found in it after standing a short time in tin vessels. The testing of vinegar for genuineness and purity involves so many complex factors that a work on food analysis, such as that of Leach, should be consulted.

Vinegar is at present used as a medicine only for its local astringent properties, and in the form of an enema diluted with three times its bulk of water to kill *seat worms.* In the *dermatitis* produced by exposure to the sun, made into a paste with glycerin, bismuth, and starch, it is very effective. In *hematemesis* one ounce to a tumbler of water often acts very advantageously, and may be taken freely. At one time vinegar was largely used in pharmacy as a menstruum, but on account of its tendency to undergo decomposition it has been replaced by diluted acetic acid in both the American and British Pharmacopœias.

Vioform. *Nioform.* $C_9H_3NOHICI$.—*Iodo-chloroxyquinoline* was introduced as a substitute for iodoform in surgery. It is a greenish-yellow, almost odorless, bulky, insoluble powder. According to the researches of E. Tavel, it is less toxic than iodoform, especially when brought in local contact with wounds, and is also more actively germicidal than is iodoform. Locally it is not at all irritant. (See *S. Jb.*, Bd. 267, p. 133; Bd. 272, p. 163.)

Viola. *Violet.*—The genus *Viola* (Fam. *Violaceæ*) includes numerous species, many, perhaps all, of which are possessed of analogous medicinal properties. *Viola tricolor* L., the *Heart's-ease, Pansy,* or *Johnny-jump-up* of the gardens, was formerly recognized by the U. S. Pharmacopœia; while *V. odorata* L., and *V. pedata* L., have held places in both the British and the United States Pharmacopœias.

V. odorata L. *Sweet Violet, Violette, Violette odorante,* Fr.; *Wohlriechendes Veilchen, Veilchen,* G.; *Violetta,* It.; *Violeta,* Sp.—This is the common violet of Europe and also the parent of the florists' violets. It resembles very closely the American blue violet, *V. cucullata* Ait., from which, however, it is at once distinguished by its greater fragrance. It is the *sweet violet* of our gardens. *V. pedata* L., or *Bird's Foot Violet* is an indigenous, stemless violet, characterized by its large blue or variegated beardless flowers, and its deeply three- to five-divided, pointed pedate leaves.

The flowers of *V. odorata* yield their odor and their slightly bitter taste to boiling water. Their infusion affords a delicate test for acids and alkalies, being reddened by the former and rendered green by the latter. Their odor is destroyed by desiccation, and the degree to which they retain their fine color depends upon the care used in collecting and drying them. They should be gathered before being fully blown, deprived of their calyx, and rapidly dried, either in a heated room or by exposing them to a current of very dry air. The flowers of other species are often mingled with them, and, if of the same color, are equally useful as a chemical test.

In the root, leaves, flowers, and seeds of *Viola odorata,* Boullay discovered an alkaloid, *violine,* allied to emetine, but possessing distinct properties. It exists in the plant combined with malic acid. Orfila asserts that it is exceedingly active and even poisonous. Linde, however (*Chem. Abstr.*, 1919, xiii, 2963) says that the amount of alkaloid in the violet roots is so small that one can scarcely attribute any toxic effect of these roots to their alkaloidal content. Mandelin (*Jahresb.*, 1883) obtained a glucoside analogous to quercitrin, which he names *violaquercitrin.* It crystallizes out of hot water in fine yellow needles. When boiled with diluted acids, it is decomposed into *quercetin, isodulcite* and a fermentable glucose,

$$C_{27}H_{30}O_{16} + 3H_2O =$$
$$C_6H_{14}O_6 + C_6H_{12}O_6 + C_{15}H_{10}O_7$$

he also obtained salicylic acid from several species of viola. (*A. J. P.*, 1882, 10.) Kraemer (*Inaug. Diss.*, Marking, 1896) detected methyl salicylate and this was later confirmed by Schimmel & Co. See also Gadd's article, *Y. B. P.*, 1905, 466.

The herbaceous parts of various species of violets are mucilaginous, emollient, and slightly laxative, and have been used in *pectoral, nephritic,* and *cutaneous diseases.* In Europe a syrup prepared from the fresh flowers of *Viola odorata* is employed as an addition to demulcent drinks, and as a laxative for infants. The root, which has a bitter, nauseous, slightly acrid taste, acts in the *dose* of from thirty grains to a drachm (2.0–3.9 Gm.) as an emetic and cathartic. It is probable that the same property is possessed by the roots of all the violets, as it is known to be by several species of *Ionidium,* which belongs to the same family. The existence in small proportion of the emetic principle in the leaves and flowers accounts for their expectorant properties.

Virginia Creeper. *Ampelopsis quinquefolia* Michx. *Psedera quinquefolia* (L.) Greene. *Parthenocissus quinquefolia* (L.) Planch. *American Ivy. Vigne vierge,* Fr. *Wilder Wein, Amerikanischer Epheu,* G. (Fam. *Vitaceæ.*)—The bark and twigs of this indigenous, woody creeper have been used by the eclectics as an alterative, tonic, and expectorant. They contain tartaric acid and potassium and calcium tartrates, albumen, sugar, pyrocatechin, and some other principles. In two cases of poisoning reported by Bernays, the symptoms were violent vomiting and purging, collapse, and deep sleep, with dilated pupils. (*P. J.*, vii.)

Viscum. *Viscum album* L. *Mistletoe. European Mistletoe. Gui de Chéne, Gillon,* Fr. *Mistel,* G. (Fam. *Loranthaceæ.*)—A yellowish-green, glabrous, evergreen, parasitic shrub with much branched and jointed stems, opposite or 3-whorled obovate-lanceolate leaves and 1-seeded, viscid, white berries growing on various trees, particularly the apple and other rosaceous fruit trees, and forming a pendent bush from two to five feet in diameter. The plant is famous in the history of Druidical superstition. In the religious rites of the Druids, the mistletoe of the oak was employed, and hence was afterwards preferred when the plant came to be used as a remedy; but it is in fact identical in all respects with those which grow upon other trees. (*P. J.*, 1897, 289.) The fresh bark and leaves have a peculiar, disagreeable odor, and a nauseous, sweetish, slightly acrid and bitterish taste. *Viscin*, which forms the glutinous constituent in the berries, leaves, and stalks of the mistletoe, is the principal constituent of *birdlime.* Crude viscin may be obtained by kneading the finely bruised mistletoe bark with water, as long as anything is dissolved, and removing the ligneous impurities mechanically. A purer product may be obtained by boiling the crude product in strong alcohol, macerating the residue with ether, evaporating the ethereal extracts, purifying these extracts by kneading first with alcohol and then with water. The formula $C_{20}H_{48}O_8$($C_{20}H_{32}$ + $8H_2O$) has been given to it by Reinsch. Pawlevsky (*Bull. Soc. Chim.* (2), 34, 348) obtained from mistletoe a crystallizable acid, slightly soluble in water, insoluble in alcohol and ether, fusing at from 101° to 103° C., to which he gave the formula $CH_3O_3.OH$. The berries, which are white, and about the size of a pea, abound in the peculiar viscid principle, and are sometimes used in the preparation of birdlime, of which this principle is the basis. Mistletoe is said to be productive of vomiting and purging when largely taken. The berries caused in a child three years old vomiting and prostration, coma, a fixed and somewhat contracted pupil, and convulsive movements. (*Ann. Thér.*, 1859, 36.) A fatal case is recorded. (*M. T. G.*, 1867, 26.) The plant was formerly looked upon as a powerful nervine, but it is now out of use. The leaves and wood were given in the *dose* of a drachm (3.9 Gm.) in substance. *Viscum* has been recommended by Gaultier (*S. M.*, 1907) for the reduction of high blood pressure in *arteriosclerosis* and other conditions of excessive arterial tension. But Dossin (*A. I. P. T.*, 1911, xxi, p. 432) finds that the lowering of blood pressure is of but short duration and is preceded by a rise and concludes, therefore, that the drug is not clinically useful for this purpose. Gaultier employed a watery extract in *doses* of 3 grains (0.2 Gm.) daily. According to P. Riehl (*D. M. W.*, xxvi, 1900), viscin affords an excellent basis for the making of applications to the skin, a benzene viscin solution mixed with starch affording an excellent plaster mass.

The *American Mistletoe* is the *Phoradendron flavescens* (Pursh.) Nutt. (*Viscum flavescens* Pursh.) It is a yellowish-green, woody parasite with jointed, branched stems, thick, obovate, persistent leaves and one-seeded berries. It grows upon the branches of deciduous trees from New Jersey to Florida and westward. Henry Dye (*Memphis Med. Recorder*, iv, 344) reported cases of poisoning from what was probably the berries of this plant. In the western part of the United States *Arceuthobium Americanum* Nutt., and *Phoradendron juniperinum* Englm., are also known under the name of mistletoe. Crawford (*J. A. M. A.*, 1911, lvii) has found that the extract of *P. flavescens* or the *P. juniperinum*, when injected into the blood stream, produces a sharp rise in the blood pressure similar to that produced by epinephrine. He also succeeded in isolating an active base, the composition of which, however, he did not satisfactorily determine, but suggests that it may be phenylethylamine. The *P. flavescens* has been more closely studied by Hanzlik and French, who find that it is a powerful stimulant to involuntary muscle, causing a rise in blood pressure and an increase in the contractions of intestine and uterus, and believe that the drug may be found clinically useful as a circulatory and uterine stimulant. It was recommended many years ago by Dr. W. H. Long as an oxytocic of great value in *post-partum hemorrhage* and *menorrhagia.* His statements have received some confirmation by other clinicians. It has also been clinically recommended as a cardiac stimulent. Dalassus proposes a formula for an aqueous *extract of mistletoe.* Five hundred parts of the ground, dry, young twigs and leaves are infused for 12 hours in 3000 parts of boiling water, expressed and the residue treated with 1500 parts of boiling water. The united liquids are then evaporated to the consistence of an extract. *Syrup of mistletoe* is made by dissolving 1 part by weight of the above extract in 10 parts by weight of boiling water and adding 990 parts of simple syrup.

Vitamins.—As far back as 1896 it was suggested that the disease known as *beri-beri*, which was then widely endemic in Asiatic countries, was associated with the predominance of rice in the diet of the Oriental peoples. Later it was shown that beri-beri occurred only on an almost exclusive diet of polished rice, that if the whole grain were employed the disease did not occur. In 1910 Frazer and Stanton (*L. L.*, 1910, i, p. 733) showed that the disease could be cured by the administration of an extract of the rice polishings. From this starting-point the work of a large number of investigators, including Funk, Hopkins, Osborne and Mendel, McCollum, etc., has developed the present vitamin theory. (For literature see Emmett, *J. A. Ph. A.*, 1921, x, p. 176.)

Without going into details of the history of the development of this hypothesis or the evidence in its support, the present accepted views may be briefly stated as follows: An animal fed on a diet calorically sufficient, composed of chemically pure carbohydrates, fats and proteins, plus the necessary mineral constituents, will not maintain its health. The failure of such a diet is due to the absence of certain elements, whose chemistry is unknown and whose mode of action is still in the realm of speculation. It was at first believed that these elements belonged among the group of amins and the word "vitamin" was coined to describe them. Although there is considerable evidence today that some of them at least are not of basic character, this word is still in current use as the name for this class of essential food stuffs. Although the term *vitaliment* has been suggested as a substitute it has not come into common use. The group of diseases which are brought about by this dietetic deficiency is known collectively as *avitaminosis.*

The amount of vitamin necessary to maintain health or even to restore health to an animal suffering from the lack of this element is so small that it is impossible to consider that their action in any way depends upon the energy which might be derived from their oxidation. Among the theories of their mode of action which have been suggested is that of Voegtlin and Myers (*A. J. Phys.*, 1919, xlix, p. 124) that they act as hormones stimulating the secretions of certain bodily glands which are essential for complete metabolism, and that of Dutcher (*J. Bi. Chem.*, 1918, xxxvi, p. 63) that their action is essentially similar to that of the catalytic agents.

While our knowledge of the chemistry of the vitamins is as yet rather hazy, Funk (*Science*, 1925, lxii, 157) believes that it is sufficient to allow us to divide them into two groups. The first of these, to which Funk would limit the term vitamin, are nitrogenous compounds easily destroyed by alkalies; the second group, which he terms *vitasterols*, are non-nitrogenous, alkali resistant and seem to belong to the sterols. They are usually denominated by the letters of the alphabet often preceded by descriptive adjectives, as *fat-soluble A*, *water-soluble B*, etc.

Vitamin A. Fat-soluble A.—This vitamin was discovered independently by Osborne and Mendel and by McCollum, in 1913. Young rats fed on a diet lacking in fat-soluble A at first grow normally then begin to lose weight and develop a characteristic disease of the eye known as *xerophthalmia* which eventually leads to complete blindness. A similar disease occurs in human beings due to similar dietetic deficiency.

Mellanby (*L. L.*, 1919, i, p. 407) and others believe that rickets is due to a deficiency of a fat-soluble vitamin but if this view be correct it is probably not the same as vitamin A. (See Hess, *J. A. M. A.*, 1921, lxxvii, 693.)

The fat-soluble vitamin is found in egg yolk, butter-fat, certain animal fats, carrots, green leaves, etc. Steenbock (*J. Bi. Chem.*, 1920, xli and 1922, li, p. 63) has noted a peculiar relation between the occurrence of the yellow pigment, carotin, and this vitamin which suggests some chemical relationship. This view, however, has not been definitely established. It resists saponification and therefore is probably not itself a fat. It withstands a temperature of boiling water for some time and is not destroyed in the process of desiccation.

Vitamin B. Water-soluble B. Anti-neuritic Vitamin.—This is found in a large number of green vegetables such as asparagus tops, bamboo sprouts, etc., probably in all growing parts of plants. It is also found in the outer layer of the cereal foods; highly-milled grains such as are used in making white bread and polished rice do not contain it. According to Daniels, Byfield and Loughlin (*Amer. Jour. of Dis. of Children*, 1919, xvi, p. 546) it is present in relatively small proportion in cow's milk as compared to human milk. It is also found abundantly in yeast and in many fruit juices. Voegtlin (*U. S. Pub. Health Rep.*, 1916) has noted that, although it is not demonstrated that phosphorus is a part of the vitamin molecule, practical experience has shown that the percentage of P_2O_5 in cereal foods runs parallel to their content of vitamin B.

Vitamin B is absorbed by Fuller's Earth (see Seidell, *A. J. P.*, 1922, xciv, p. 440). It is destroyed by alkalies and hence is not found in bread made with unneutralized baking soda, even if whole wheat be used. In slightly acid solutions it will withstand temperature of boiling water for a short period of time.

Vitamin C. Anti-scorbutic Vitamin.—It has long been known that the absence of certain foods leads to the occurrence of *scurvy* and it has also been known that the administration of lemon juice, raw potatoes and other vegetable foods will prevent or cure this disease. This disease is now believed to be due to the absence of an essential element which is ordinarily known as *water-soluble C.* This vitamin, in some ways, is the most unstable of all the known vitamins. It is so easily destroyed by heat and oxidation that few of the canned or desiccated foods contain any large proportions. Eckman (*J. A. M. A.*, 1922, lxxviii, p. 635) tested 7 kinds of desiccated fruits and found that the only one of these which contained sufficient antiscorbutic vitamin to maintain life, in the guinea pig, was dried peaches, and even this was not successful for an indefinite period of time. It is found most abundantly in lemons, tomatoes and in other raw fruits including bananas, apples, etc. Curiously, it is present in relatively small proportion in limes. (The lime juice which was formerly provided to the British Navy as a protective against scurvy was the juice of the lemon, not of the fruit known in this country as the lime.) It is found also abundantly in certain root foods, as turnips and potatoes, and to a lesser extent in some green vegetables. The fact that this vitamin is so often associated with fruit acids led at one time to the theory that itself was an acid. This old view has been thoroughly disproven. The vitamin, however, is destroyed by alkalies.

As most of the methods for the preservation of foods that are at present in commercial use have destructive action on water-soluble vitamin C, the use of raw foods is essential in the treatment or prevention of scury.

There are a number of other diseases which have been attributed to lack of similar elements in the diet but which have not been so firmly established as deficiency diseases. Among these may be mentioned especially *pellagra* and *rickets.* There is considerable evidence that the latter disease is dependent on the lack of a fat-soluble vitamin, which some identify with vitamin A described above but others believe it to be a separate fat-soluble vitamin (see McCollum and Simmonds, *J. Bi. Chem.*, 1922, liii, 293) while still other authorities maintain that rickets is not a dietetic disease. One reason which has been advanced for the opinion that rickets is not a deficiency disease is based upon the fact that therapeutic results in this disorder are produced by sunlight, similar to those brought about by the administration of cod liver oil whose efficacy has been believed to demonstrate the presence of a vitamin. Curiously enough it has recently been shown that cod liver oil is radioactive and that certain other oils which are ordinarily not beneficial in rickets may be endowed with curative properties by exposing them to ultra-violet radiation.

While it may be regarded as well established that certain disorders may be attributed to vitamin deficiency there has been an extraordinary amount of popular misconception and consequent mulcting of the public by manufacturers of various proprietary preparations. In the first place, it should be remembered that on an ordinary mixed diet such as is commonly employed by American and European peoples there is practically no danger of avitaminosis; raw milk contains in itself all the necessary vitamins and even in those cases where it is necessary to boil the milk—which may destroy the antiscorbutic vitamin—the addition of a small quantity of lemon juice or orange juice makes up for this deficiency. Even when milk is not part of the diet the man who uses a certain modicum of butter and some raw vegetable food, as lettuce or celery or parsley, with a fairly variegated diet need have no fear of vitamin deficiency. In the second place, while a lack of vitamin is deleterious to the health there is no evidence that an excess of vitamin is beneficial. Various assertions have been made concerning the therapeutic value of vitamin excess but they are not scientifically confirmed. In the third place, if there be need of an increase in one or the other of the vitamins this can be met much more economically by the use of some food known to contain large amounts of that vitamin than by the administration of any medicinal product. Finally many of the proprietary vitamin preparations on the market are rank frauds. McCollum and Simmonds (*J. A. M. A.*, 1922, lxxviii, p. 1953) investigated seven of these supposed vitamin concentrations and found that none of them would protect against avitaminosis even although given in 20 times the recommended dose. For references to the literature on vitamins, see paper by Emmett (*J. A. Ph. A.*, 1921, p. 176).

Warburg's Tincture.—This famous remedy, at first a proprietary medicine, afterwards by the voluntary act of its inventor had its formula revealed. A simplified form of it is recognized by the N. F. There is so much testimony as to its extraordinary virtues in the severe *remittent* and *pernicious malarial fevers* of India that its powers can scarcely be questioned. After the bowels of the patient in the acutest stage of the disorder have been freely opened, a half ounce of the tincture is given undiluted, all drink being withheld, and at the end of three hours a second half ounce is given in a similar manner. Soon after the second dose a violent, aromatic perspiration comes on, and the fever is usually broken. The remedy is also commended in *collapse* without organic disease. The formula given by Warburg is as follows: Socotrine aloes 1 lb.; rhubarb, angelica fruit, confection of Damocratis, each 4 oz. troy; elecampane, saffron, fennel, prepared chalk, each 2 oz. troy; gentian, zedoary, cubebs, myrrh, camphor, agaric, each 1 oz., troy. Digest the whole with 500 oz. proof spirit in a water bath for 12 hours, express, add 10 oz. sulphate of quinia, dissolve by the aid of a water bath, cool, and filter.

It is evident that *Warburg's tincture* contains various substances which are inert, but the practical difficulty is to determine as to what its extraordinary value anti-malarial powers are really due. The formula used in the U. S. Army, with asserted excellent results in Cuba, has the advantage of yielding a product in tablets, which is as follows: Aqueous extract aloes, 224 grains; rhubarb, 448 grains; angelica seed, 448 grains; elecampane, 224 grains; saffron (Spanish), 224 grains; fennel, 224 grains; gentian, 112 grains; zedoary root, 112 grains; cubeb, 112 grains; myrrh, 112 grains; white agaric, 112 grains; camphor, 112 grains; quinine sulphate, 1280 grains. Exhaust with eight pints of diluted alcohol, or divide into 1024 tablets.

The confection of Damocratis, in the original, which was a combination of thirty aromatic substances mostly obsolete, may be found in the 19th ed., *U. S. D.*, p. 1695. It is contained in the formula in such small amount that it is hardly possible that it could have any effect. (See also *Tinctura Antiperiodica*, N. F., Part III.)

The National Formulary has revised the formula of Warburg's tincture and there are two tinctures, one with and one without aloes.

Dose.—The dosage of Warburg's tincture depends on the kind used—whether with aloes or without—and the intended purpose, and varies from 4 cc. (1 fluidrachm) to 15 cc. (4 fluidrachms). The larger quantity is given when Doctor Warburg's original directions are followed for administering the remedy in remittent fevers. These directions were as follows: "One-half ounce to be given alone, without dilution, after the bowels have been evacuated by any convenient purgative, all liquids being withheld. After three hours another half ounce is to be given."

Watercress. *Cresson de fontaine*, Fr. *Brunnenkresse*, G.—*Radicula Nasturtium aquaticum* (L.) Britten et Rendle. (*Nasturtium officinale* R. Br.) (*Roripa Nasturtium* Rusby) (Fam. *Cruciferæ.*) In sensible and medicinal properties watercress bears some resemblance to scurvy grass, though milder, and on this account is preferred for the table. It is useful in *scorbutic affections.* It contains a volatile oil, which according to A. W. Hofmann, contains as its chief constituent a body boiling at 253° C., which he considers to be the nitrile of *phenyl-propionic acid*, and therefore has the formula $C_9H_{10}N$. Greenish states that the chief constituent is phenyl-ethyl iso-thiocyanate. The expressed juice is sometimes given in the *dose* of one or two fluidounces (30–60 cc.); but the herb is more frequently used in the form of a salad.

Other species of *Radicula* grow in similar situations with the *R. Nasturtium*, and act similarly.

Water Melon.—This popular fruit, *Citrullus vulgaris* Schrad., is a native of Asia but is largely cultivated all over the world. Both the pulp and the seeds have been attributed with diuretic properties. Power and Salway (*P. J.*, lxxxiv, p. 760) found in the seeds a fixed oil similar to that of pumpkin seeds. There is no convincing evidence that this fruit contains any medicinally active ingredient.

White Ash Bark. *Fraxinus.*—The N. F. formerly recognized "the dried bark of *Fraxinus americana* Linné (Fam. *Oleaceæ*) and probably of other species of *Fraxinus*, deprived of the corky layer." *N. F. IV.*

The white ash is a large tree of the northern United States and Canada. The bark occurs "in flat pieces of varying length and width, from 3 to 6 mm. in thickness, externally yellowish or pale brown, sometimes with ridges of a warty nature and fissures of a grayish-brown color with markings of lichens; inner surface, pale brown to yellowish, longitudinally striate; fracture very uneven, fibrous. Odor faintly aromatic; taste bitter, weakly acrid. Fraxinus yields not more than 10 per cent. of ash." *N. F. IV.* It contains a volatile oil, an alkaloid and several resins. The bark has been used in *dysmenorrhea* by Charles P. Turner and others.

Fraxinus excelsior L. *Frêne*, Fr. *Esche*, G. *Fresco*, Sp. (Fam. *Oleaceæ.*)—The bark of the *Common European Ash* occurs in quills and is of a grayish or grayish-green color. It is bitter and astringent, and at one time was employed in the treatment of *intermittent fever.* It contains a crystalline glucoside and a bitter principle, and a fixed oil obtained from the seeds. (*Chem. Ztg.*, 1911, 478.) The leaves were formerly used in *rheumatic affections* and *gout*. *Dose*, an ounce (30 Gm.), usually in infusion.

Whiting.—This is essentially the same as prepared chalk, being made by the pulverization and elutriation of crude chalk. It is used as a coarse paint, and for various purposes in the arts, for which calcium carbonate is requisite. *Paris white* is a variety of the same material.

Winter's Bark. *Wintera.*—The bark of *Drimys Winteri* Forst. *Cortex Winteranus. Ecorce de Winter, Cannelle de Magellan*, Fr. *Winter's Zimmt*, G. (Fam. *Magnoliaceæ.*)—For descriptions of tree, see *U. S. D.*, 16th edition. The tree is a native of the southern part of South America, growing along the Strait of Magellan, and extending as far north as Chile. The commercial supply now comes chiefly from Colombia. This bark was brought to England, in the latter part of the sixteenth century, by Captain Winter, who attended Drake on his voyage round the world, and while in the Strait had learned its aromatic and medicinal properties. Since this period, from time to time various barks have appeared in European commerce as *Winter's bark*. Among these are the bark of *Cinnamodendron corticosum* Miers. (Fam. *Canellaceæ*), of Jamaica, which is pungent like true Winter's bark, but is of a much paler brown color, and resembles canella bark except in the absence of the chalky-white inner surface, and the bark of *Croton Malambo* Karst. (Fam. *Euphorbiaceæ*), which resembles in color and thickness the bark of the *Cinnamodendron*, but has a bitter taste and a calamus-like flavor. P. N. Arata and F. Canzonri (*P. J.*, June 14, 1890) describe a bark which they assert to be a genuine Winter's bark from the Strait of Magellan. From this they separated a volatile oil by distilling the bark with water, exhausting the distillate with petroleum, and distilling off the solvent. The crude oil, amounting to 0.64 per cent. of the weight of the bark employed, was a mixture of several substances. *Winterene*, $C_{15}H_{24}$, is the essential oil separated from this by fractional distillation. It is readily oxidized on exposure to the air, becoming yellow. The formula $C_{25}H_{40}$ was calculated from the ultimate analysis and vapor density, but the authors consider that the ready oxidizability of winterene and its analogy to similar essences point rather to the formula $C_{15}H_{24}$, which would place it in the group of sesquiterpenes, such as cedrene, cubebene, etc. The presence of tannic acid and ferric oxide, according to Henry, serves to distinguish Winter's bark from *Canella alba*, with which it has often been confounded. The bark above described as commercial Winter's bark is destitute of both tannic acid and ferric oxide, and cannot therefore be the bark examined by Henry.

The bark of the *Drimys granatensis* L. f. (now regarded as identical with *D. Winteri* Forst.), has been imported into London under the name of *Merida coto*, and it has been stated that it contains *cotoin*. It occurs in short pieces of a yellowish-gray color, traversed longitudinally by hard cellular layers, which distinguish it at once from coto and paracoto bark. Its odor resembles that of true coto, but is more feeble. A careful chemical study of it by O. Hesse (*P. J.*, vol. iv) shows that it contains no cotoin, but a crystalline substance, $C_{13}H_{14}O_4$, to which the name of *drimin* was given. From the leaves Hesse obtained a wax alcohol, *drimol*, $C_{28}H_{58}O_2$. As *Drimys granatensis* L. f., is recognized as *D. Winteri* Forst., it is plain that Merida coto must be looked upon as a form of Winter's bark coming from Venezuela.

Winter's bark is a stimulant aromatic tonic, and was employed by Winter as a remedy for *scurvy*. It may be used in half-drachm (2.0 Gm.) *doses* for similar purposes with cinnamon or canella alba, but is scarcely known in the medical practice of this country. *Drimys chilensis* of De Candolle, growing in Chile, yields a bark having similar properties (Carson, *A. J. P.*, xix, 81) also *D. aromatica* F. Muell., of Australia. (*P. J.*, xxi.)

Wistaria. *Wisteria sinensis* Sweet (*W. chinensis* DC.) (*Krauhnia sinensis* Makino.) *Wisteria. Chinese Wisteria.* (Fam. *Leguminosæ.*)—Ottow (*P. J.*, Oct., 1886) has obtained from this ornamental woody climber a crystalline poisonous glucoside, *wistarin*.

Withania. *Withania coagulans* Dun. (Stocks.) *Vegetable Rennet.* (Fam. *Solanaceæ.*)—This shrub, common in Afghanistan and East India, has the property of coagulating milk, and has been used for preparing a vegetable rennet ferment for making cheese. Sheridan Lea found upon examination that the substance which possesses the coagulating power is a ferment closely resembling animal rennet. The active principle is soluble in glycerin, and can be extracted from the seeds by this solvent; the extract possesses strong coagulating powers even in small amounts. Alcohol precipitates the ferment body from its solutions, and the precipitate, after washing with alcohol, may be dissolved again without having lost its coagulating powers. The active principle of the seeds will cause the coagulation of milk when present in very small quantities, the addition of more of the ferment simply increasing the rapidity of the change. The coagulation is not due to the formation of acid by the ferment. If some of the active extract be made neutral or alkaline, and added to neutral milk, a normal clot is formed, and the reaction of the clot remains neutral or faintly alkaline. The clot formed by the action of the ferment is a true clot, resembling in appearance and properties that formed by the animal rennet, and not a mere precipitate. Lea prepared an active extract, applicable for cheese making purposes, by grinding the dry seeds very finely in a mill, and extracting them for twenty-four hours with such a volume of 5 per cent. sodium chloride solution that the mass is still fluid after the absorption of water by the fragments of the seeds as they swell up. From this mass the fluid part may be readily separated by centrifugation. Forty grammes of the seeds treated as above, with 150 cc. of 5 per cent. sodium chloride solution, gave an extract of which 0.25 cc. clotted 20 cc. of milk in twenty-five minutes, and 0.1 cc. clotted a similar portion of milk in one hour. When added in these proportions the curd formed is quite white. The presence of the coloring matter is, however, perhaps on the whole unimportant, since even if a larger quantity of the ferment extract is added in order to obtain a very rapid coagulation, the coloring matter is obtained chiefly in the whey, the curd being white; by adding sufficient common salt to make the percentage up to 15 per cent., and alcohol up to 4 per cent., the preparation would retain its activity very well. (*P. J.*, 1884, 606.)

Wurrus.—Under the name of *Vars, Wars*, or *Warrus*, a powder somewhat similar to kamala has been used as an anthelmintic in Southern Arabia, and exported into commerce from Aden. It is obtained from the fruits of *Flemingia congesta* Roxb. (Fam. *Leguminosæ.*) (*P. J.*, Sept., 1887.) It has a dull purplish color and under the microscope is observed to consist of simple non-glandular hairs and glandular hairs, the latter characterized by large oblong resinous heads with 3 or 4 tiers of elongated cells. It contains *flemingin, homoflemingin* and resins.

Xanthium. *Cocklebur. Clotbur.* (Fam. *Compositæ.*)—This is a genus of coarse annual weeds having branched stems bearing alternate toothed or lobed, often cordate, leaves and burs clothed with characteristically hooked prickles. Guichard believes that he has found an alkaloid in the *X. spinosum* L. (*P. J.*, vii, 249.) In the *Xanthium Strumarium* L., which is common both in Europe and in America, A. Zander believes that he has found a glucoside, *xanthostrumarin.* M. V. Cheatham thinks that there is a second active principle. (See *A. J. P.*, vol. xi, 271; vol. xiv, 134.) Clotbur is stated to be an active styptic, both local and general. *Dose,* of the fluidextract, from one to two fluidrachms (3.75–7.5 cc.).

Xanthorrhiza. *Yellow-root. Shrub Yellow-root. Zanthorhiza apiifolia* L'Her. (*Xanthorrhiza apiifolia* L'Her.) (Fam. *Ranunculaceæ.*)—This is a low shrub, with a horizontal rhizome, which sends off numerous suckers. The stem is simple, about 5 mm. thick, with a smooth bark and bright yellow wood. The leaves are compound, consisting of several ovate-lanceolate, acute, doubly serrate leaflets, sessile upon a long petiole, which embraces the stem at its base. The flowers are small, purple, and disposed in long, drooping, divided racemes, placed immediately below the first leaves. Yellow-root grows from southern New York to Georgia and west to Kentucky. It flowers in April. The root was formerly in the Secondary List of the U. S. Pharmacopœia, but the bark of the stem possesses the same virtues. The root is from 7 cm. to 1 dm. in length, and about 12 mm. thick near the stem. It shrinks somewhat in drying, and, as found in commerce, is in slender pieces of various lengths, wrinkled longitudinally, with a light yellowish-brown, easily separable epidermis, a thick, hard, bright yellow woody portion, and a very slender central pith. It is inodorous, and of a simple but extremely bitter taste. It imparts its color and taste to water. The infusion is not affected by ferric salts. J. Dyson Perrins found *berberine* in it. (*P. J.*, May, 1862.) Samuel S. Jones believed that he had proved the existence in the drug of a second alkaloid. (*A. J. P.*, vol. xvi, 1861.) *Xanthorrhiza* possesses properties closely analogous to those of calumba, quassia, and other simple tonic bitters, and may be used for the same purposes and in the same manner. Woodhouse employed it in the *dose* of forty grains (2.6 Gm.).

Xanthorrhœa Resin. *Gum Accroides. Yacca Gum. Accroides Resin. Earth Shellac. Grass-tree Gum. Botany Bay Gum.*—Yellow and reddish resinous substances, the products of *Xanthorrhœa hastilis* R. Br. and *X. australis* R. Br. (Fam. *Liliaceæ*), have been introduced into England from Australia. They are obtained by spontaneous exudation from the stems of the plants, which are usually shrubs. The *yellow resin* (from *X. hastilis*) is in tears, in flattish pieces having on one side the mark of the stem, or in masses of various size and irregular shape. It has a reddish-yellow color, resembling gamboge when broken, and when heated emits a fragrant odor like that of Tolu balsam. It contains resin, cinnamic and benzoic acids, and a trace of volatile oil, and may therefore be ranked among the balsams. When heated with nitric acid, it yields a large proportion of picric acid. In medicinal properties it is said to bear a close resemblance to storax and the balsam of Tolu. The natives and early settlers employed it as a medicine in *diarrhea.* It is said to be used extensively, instead of shellac, as a resinous glaze for confectionery and also in cabinet work, but to be distinctly inferior. For much interesting information concerning it and other resinous products of the genus *Xanthorrhœa,* see paper by J. H. Maiden, *P. J.*, 1891, xxi. A tincture, made in the proportion of two ounces to a pint of alcohol, may be given in the *dose* of one or two fluidrachms. The *red variety* (from *X. australis* R. Br.) resembles dragon's blood in color, and appears to be analogous to the other variety in properties. Enormous quantities of this resin were imported into Germany before the war, although for what purpose is unknown, perhaps as a source of picric acid. It is now widely used in making varnishes and also linoleum. (See *Ph. Era,* 1921, liv, 366; also *D. C.*, 1895, p. 83.)

Xylene. *Xylol. Xylène,* Fr. *Xylol,* G. $C_6H_4(CH_3)_2$.—There are three isomeric hydrocarbons of this name, the ortho-, meta-, and para-xylene respectively, all contained in coal tar. A mixture of them was first extracted from naphtha by Hugo Müller, and was brought forward by Zuelzer as a specific in *smallpox,* but is useless. (*P. J.*, 1872, 623.) Volpino (*P. J.*, 1920, civ, 171) on the basis of experiments on guinea-pigs and some clinical observations has suggested its use in *tuberculosis.* It is largely used as a solvent.

Yadil. *Trimethenal-allyl-carbide.*—This preparation has been used in the treatment of *influenza.* The doses employed have varied enormously but it has been mostly employed in doses of about one fluidrachm (4 cc.) several times a day.

Yohimbe.—This is the bark of *Corynanthe Johimbi* Schum. (*Pansinystalia Yohimbe* (Schum.) Pierre), a rubiaceous tree growing in the southern Cameroons district in Africa. The bark comes into commerce in flattened or slightly quilled pieces 75 cm. long to 4 to 8 mm. thick, with an external corky layer of a gray-brown color covered with isolated lichens. It shows numerous longitudinal and transverse fissures like some old specimens of cinchona bark. The transverse fracture is of a uniform yellowish-brown color, and presents short, soft fibers like rough velvet. The taste is bitter. For a history of Yohimbe bark consult *Pharm. Zentralh.*, 1921, p. 169.

This bark contains at least three alkaloids, Siedler (*Ph. Ztg.*, 1902) says five. The most important of these is *yohimbine,* discovered by Spiegel in 1896; it is asserted by Fourneau and Page (*B. Sc. Pharm.*, 1914, xxi, 7) to be identical with quebrachine (see *Aspidosperma*), but there is some difference of opinion as to its chemical composition. *Mesoyohimbine* is isomeric with it; *yohimbinine,* also present, seems to be physiologically inert. For further data on the chemistry of these substances which is at present in an unsettled state, see Spiegel (*B. Chem. G.*, 1915 and 1916), Ewins (*Tr. Chem. Soc.*, 1914, cv) and Barger and Field (*Tr. Chem. Soc.*, 1923, cxxiii).

The salt of this base that is ordinarily used is the hydrochloride, being preferable on account of its solubility and high percentage of the alkaloid.

Yohimbine was physiologically studied by Oberwarth and Loewy (*V. A. P. A.*, cliii, and *B. K. W.*, No. 42, 1900), who found it to be in animals and also in man a very active excitant to the sexual organs and functions. On the other hand, Kravkoff, as the result of experiments upon the lower animals and upon man, concluded that it has no aphrodisiac effects and frequently produces nausea, salivation, irritability, and other disagreeable results.

Müller (*A. I. P. T.*, 1907, p. 65) found that yohimbine in small doses stimulated, and in large doses depressed, the respiratory center. If lethal doses are given the heart continues beating after the respiration has ceased. Small doses have little effect upon the blood pressure, but moderate-sized doses caused a slight rise in the blood pressure with local dilatation of the vessels of the pelvic organs. He believes that its aphrodisiac action is due to an increase in the excitability of the lower centers in the spinal cord. On the other hand, many authors believe that its effect is due to the hyperemia produced. Toff (*D. M. W.*, 1904) has found it useful because of this effect in scanty or *irregular menstruation.*

It has been used by numerous clinicians in *neurasthenic impotence*, with reports which are generally favorable to its influence. (For literature, see *M. R.*, 1901, 1902.) It is said to be of no value when the impotence depends upon organic nerve trouble, and to be harmful when it is caused by chronic inflammatory disease of the sexual organs or of the prostate gland. It has also been employed in *angina pectoris* and arteriosclerosis (Staehelin, *Th. M.*, Sept., 1910). *Dose*, of the hydrochloride, 0.005 Gm. (one-twelfth grain), either in tablet or solution, three or four times a day. Yohimbine has also been employed in a 1 per cent. solution hypodermically.

Zerumbet. *Cassumuniar.*—Under these names an East Indian root was formerly used, having some analogy in sensible and medicinal properties to ginger, and ascribed to the *Zingiber Zerumbet* of Roscoe. By some authors the zerumbet has been erroneously confounded with the round zedoary. Geiger describes it as in pieces of the size of a fig or larger, externally grayish-brown and wrinkled, internally yellowish, hard and tough, of a biting, aromatic taste and a spicy odor.

Zinc Borate. *Zinci Boras.* $ZnB_4O_7 + 7H_2O$.—Prepared by mixing an aqueous solution of zinc sulphate (1 in 10) with one of borax (1 in 25), and collecting the precipitate. Used as an antiseptic dusting powder.

Zinc Bromide. *Zinci Bromidum. U. S. VIII. Zincum Bromatum. Bromure de Zinc,* Fr. *Bromzink, Zinkbromid,* G. *Bromuro zincico*, Sp. $ZnBr_2 = 225.21$.—"It should contain, when anhydrous, at least 97 per cent. of pure Zinc Bromide, and should be kept in small, glass-stoppered bottles." *U. S. VIII.*

It is "a white, or nearly white, granular powder; odorless, having, even in dilute solutions, a sharp, saline and metallic taste. Very deliquescent. Readily soluble in water and alcohol. When heated to 394° C., the salt fuses, and, with a careful increase of heat, may be sublimed in the form of needle-shaped prisms. Its aqueous solution gives a slightly acid reaction with blue litmus-paper." *U. S. VIII.*

Zinc bromide is capable in excessive doses of acting as an irritant poison. It has been commended in *epilepsy*, but is of no value.

Dose, one to two grains (0.065–0.13 Gm.).

Zinc Cyanide. *Zinci Cyanidum.* $Zn(Cn)_2$.—This cyanide is precipitated as a white insoluble powder, by adding cautiously, until it ceases to produce a precipitate, a recently filtered solution of potassium cyanide to a solution of zinc sulphate. It is used in Germany as a substitute for hydrocyanic acid, and is said to be anthelmintic. It has been recommended by Lashkevich in *cardiac neuroses* in doses of from one-tenth to one-eighth grains (0.006–0.008 Gm.) three times a day. It has been employed in *epilepsy, chorea* and *neuralgia,* in several *painful affections of the stomach* and in the *colics* attendant on *difficult menstruation.* The *dose* is a quarter of a grain (0.016 Gm.), gradually increased to one grain (0.06 Gm.), given in mixture.

Zinc Ferrocyanide. *Zinci Ferrocyanidum.* $Zn_2Fe(Cn)_6 + 3H_2O$.—Formed by double decomposition between hot solutions of potassium ferrocyanide and zinc sulphate. It is precipitated as a white powder. It has similar medicinal properties to those of the cyanide, and is used in the same diseases. The *dose* is from one to four grains (0.065–0.26 Gm.), given in pill.

Zinc Iodide. *Zinci Iodidum. U. S. VIII. Zincum Iodatum. Iodure de Zinc,* Fr. *Zinkjodid, Jodzink,* G. $ZnI_2 = 319.21$.—"It should contain, when anhydrous, not less than 98 per cent. of pure Zinc Iodide, and should be kept in small, glass-stoppered bottles protected from light." *U. S. VIII.*

It is "a white, or nearly white, granular powder; odorless, and having a sharp, saline and metallic taste. Very deliquescent, and, upon exposure to air and light, becoming brown from liberated iodine. Readily soluble in water, alcohol, or ether. When heated to about 446° C., the salt fuses to a colorless liquid, and at a higher temperature sublimes, forming quadratic needles, while a small part is decomposed and leaves a residue of zinc oxide. Its aqueous solution reddens blue litmus paper." *U. S. VIII.* For further tests see *U. S. D.*, 20th ed., p. 1672.

Zinc iodide was proposed many years ago as an alterative remedy in *chorea, scrofula* and *hysteria* but is no longer employed. The best form of administration is in *syrup*, to protect it from change. (See p. 1353, *U. S. D.*, 19th ed.) A solution containing from one to two grains (0.065–0.13 Gm.) to the fluidounce (30 cc.) of water has been used as an astringent injection in *gonorrhea.*

Dose, one-half to two grains (0.032–0.13 Gm.).

Zinc Lactate. *Zinci Lactas.* $Zn(C_3H_5O_3)_2 + 3H_2O$.—This salt was used by Herpin in *doses* of two grains (0.13 Gm.), three times a day, gradually increased to ten grains (0.65 Gm.) a day, as a substitute for zinc oxide in *epilepsy.* For its physical properties and methods of preparation see 16th edition, *U. S. D.*

Zinc Permanganate. *N. N. R.* 1924. *Zinci Permanganas. Zinkpermanganat, Uebermangansaures Zink,* G. $Zn(MnO_4)_2 + 2H_2O$.—Made by precipitating barium permanganate with zinc sulphate, using exact molecular proportions. It forms dark brown, almost black, deliquescent crystals, giving off oxygen even more readily than does potassium permanganate. It dissolves in about 3 parts of water, usually with a slight residue. The solution decomposes if exposed to the air. It is incompatible with peroxides, acids, ammonia and hypophosphites, and must not be triturated with organic substances. Zinc permanganate possesses the disinfectant powers of the other permanganates but is more astringent. It is used chiefly as an injection in *urethritis* in strengths of about 1 to 4000 as an astringent and antiseptic application.

Zinc Phenolsulphonate. *Zinci Phenolsulphonas, U. S. IX. Zinci Sulphocarbolas*, Br. 1898; *Zincum Sulphophenolicum; Zinc Paraphenolsulphonate.*—" It contains not less than 73.7 per cent. nor more than 77.4 per cent. of anhydrous zinc phenolsulphonate, corresponding to not less than 99.5 per cent. of the crystallized salt $[(C_6H_5O.SO_3)_2Zn + 8H_2O = 555.72]$. Preserve it in small, well-closed containers." *U. S. IX.*

This salt, which was dropped at the tenth revision of the *U. S. P.* was officially described as in " colorless, transparent, rhombic prisms or tabular crystals or in granular form; odorless, and having an astringent, metallic taste. When exposed to the air the salt effloresces, and upon exposure to light and air may become slightly pink. One Gm. of Zink Phenolsulphonate dissolves in 1.6 mils of water, and in 1.8 mils of alcohol at 25° C.; also in 0.4 mil of boiling water. Its aqueous solution (1 in 10) is acid to litmus. When heated to 125° C., the salt loses all of its water of crystallization. At a higher temperature it chars, emitting inflammable vapors having the odor of phenol, and finally leaves an incombustible residue. An aqueous solution of the salt (1 in 20) yields a white, gelatinous precipitate with potassium ferrocyanide T.S., and a white precipitate with ammonium sulphide T.S. Ammonium carbonate T.S., when added in small portions to an aqueous solution of the salt (1 in 20), produces a white precipitate which redissolves completely upon the addition of an excess of the reagent. A dilute solution of the salt (1 in 100) is colored pale violet by ferric chloride T.S. The addition of a few drops of barium chloride T.S. to 10 mils of an aqueous solution of the salt (1 in 20), previously acidulated with 3 drops of hydrochloric acid, produces not more than a slight turbidity (*sulphate*). Ten mils of an aqueous solution of the salt (1 in 50), to which 1 mil of diluted hydrochloric acid has been added, does not respond to the Test for heavy metals. An aqueous solution of the salt meets the requirements of the Test for arsenic.

"*Assay.*—Dissolve about 1 Gm. of Zinc Phenolsulphonate, accurately weighed, in 100 mils of distilled water and proceed as directed in the assay under *Zinci Acetas.* The amount of zinc oxide obtained corresponds to not less than 73.7 per cent. nor more than 77.4 per cent. of $Zn(C_6H_5O_4S_2)_2$.

" Each gramme of Zinc Phenolsulphonate corresponds to not less than 0.146 Gm. nor more than 0.153 Gm. of ZnO.

" Zinc Phenolsulphonate may also be assayed by the Electrolytic method." *U. S. IX.*

Zinc phenolsulphonate has been employed as an antiseptic and astringent application to indolent or foul *ulcers,* and in subacute inflammations of the mucous membrane. The solutions used may be a little stronger than those of zinc sulphate employed for similar purposes. It has also been used as an intestinal antiseptic.

Dose, one to three grains (0.065–0.2 Gm.).

Zinc Phosphate. *Zinci Phosphas. Trizincic Orthophosphate.* $Zn_2(PO_4)_2 + 4H_2O$.—Zinc phosphate may be prepared by the mutual reaction of zinc sulphate and an alkaline phosphate. Zinc phosphate is a white powder, insoluble in water but soluble in acids. It was at one time used in the treatment of various nervous diseases. It is largely used in dental cements.

Zinc Phosphide. *Zinci Phosphidum. U. S.* 1890. $Zn_3P_2 = 258.19$.—According to Hager, *zinc phosphide* was first prepared by Marggraf in 1740. It was formerly made by fusing, in a bath of iron filings, 74 parts of pure zinc, and adding gradually, in small pieces, 26 parts of dry phosphorus. This process gives good results only in small quantities (10 to 20 Gm.). A more recent process is to pass vapors of phosphorus in a current of dry hydrogen over fused zinc. The product is a spongy, gray mass, of metallic appearance, containing rhomboidal crystals, and when powdered resembling somewhat reduced iron. The particles of metallic zinc should be separated. Its sp. gr. is 4.72. " Zinc phosphide should be kept in small, glass-stoppered vials." *U. S.*, 1890.

It occurs as " a gritty powder of a dark gray color, or crystalline fragments of a dark, metallic luster, and having a faint odor and taste of phosphorus. In contact with the air it slowly emits phosphorous vapor. Insoluble in water or alcohol. Soluble in diluted hydrochloric or sulphuric acid with evolution of hydrogen phosphide. When strongly heated, with exclusion of air, it melts and finally sublimes. When heated in air, it becomes oxidized to zinc phosphate." *U. S. VIII.* For a method of assay of zinc phosphide, see *N. R.*, June, 1879.

It has been proved by direct experiment upon animals, as well as by clinical experience, that zinc phosphide affects the system physiologically and therapeutically in exactly the same manner as does phosphorus, and it is employed in medicine as a substitute for that element. Theoretically, each grain of the phosphide contains nearly a quarter of a grain of phosphorus. It is asserted in the journals to have been administered in doses of one or even two grains; but of the pure salt such amounts would be extremely dangerous; the commencing *dose* is one-twentieth of a grain (0.003 Gm.).

Zinc Salicylate. *Zinci salicylas. Zinksalicylat,* G. $Zn(C_6H_4.OH.COO)_2 + 3H_2O$.—Made by boiling together molecular proportions of sodium salicylate and zinc sulphate, cooling, washing the crystals and recrystallizing from hot water. In the form of long satiny needle-like crystals, having a sweet but astringent and bitter taste. It is soluble in about 20 parts of cold water. Zinc salicylate is an astringent and antiseptic, a solution (one-fifth to one per cent.) is used in *ophthalmia* and *gonorrhea.* It is incompatible with iron compounds and with mineral acids.

Zinc Subgallate. *Zinci Subgallas.*—An odorless powder containing 44 per cent. of zinc oxide and 56 per cent. of gallic acid. Internally it is used in intestinal disorders as an antiferment in *doses* of from one-half to four grains (0.032–0.26 Gm.). It is incompatible with iron compounds and with alkaloidal salts. Externally it has been used in *skin diseases.*

Zinc Sulphite. *Zinci Sulphis.* $ZnSO_3 + 2H_2O$. —Made by precipitating a solution of zinc sulphate with sodium sulphite, collecting, washing and drying the precipitate. A white crystalline powder, soluble in about 600 parts of water.

Zirconium. $Zr = 90.6$.—*Zirconium dioxide* is a heavy white insoluble powder which has been used by Kaestle (*M. M. W.*, 1909) for making X-ray examinations of internal organs. According to this author it is the most opaque substance available except thorium oxide and has the advantage of being much cheaper.

Zizyphus. *Zizyphus sativa* Gaertn. (*Z. vulgaris* Lamarck.) *Common Jujube, Jujube,* Fr. *Brusthbeeren, Judendornbeeren,* G.—A shrub, or small tree, of the Fam. *Rhamnaceæ*, growing on the shores of the Mediterranean, and cultivated in Italy, Spain, and Southern France. It has become naturalized in Alabama. The fruit is the part used. This consists of oval drupes, of the size of a large olive, with a thin, coriaceous, red or reddish-brown skin, a yellowish, sweet, acidulous pulp, and an oblong, pointed stone in the center. These have the name of *jujubæ.* By drying, their pulp becomes softer and sweeter, and acquires a vinous taste, evincing the commencement of fermentation. They are nutritive and demulcent, and are used in the form of decoction in *pectoral complaints. Jujube paste* consists properly of gum arabic and sugar, dissolved in a decoction of this fruit and evaporated to the proper consistence. As a demulcent it is in no respect superior to a paste made with gum arabic and sugar alone, and the preparation formerly sold in this country under the name contains in fact none of the fruit. The fruits of two other species, *Z. Lotus* Lam., growing in the north of Africa, and *Z. Jujuba* Lam., a native of Syria, possess properties similar to those of the *Z. sativa* and are used as food by the inhabitants of the countries where they grow. The *Zizyphus Jujuba* is stated by Rixford (*Stand. Cycl. Hort.*, 1922, p. 3548) to produce the best fruits. It has been cultivated in Northern China for many centuries and is now under cultivation in Mediterranean countries, California and neighboring states. The fruits which are subglobose to oblong, orange-red drupes, have been esteemed for throat troubles in the form of pastes, tablets and syrups. It is also one of the sources of *lac.*

Zygadenus. *Death Camas.*—At least nine species of this liliaceous genus, found in the Western United States, are highly toxic to grazing animals, notably to sheep. *Zygadenus venenosus* Watson, probably the most extensively studied of these, is a perennial herb having a tunicated bulb from which arise a rosette of very narrow dark green basal leaves and a scape 1 to 2 feet high which bears a spike of yellowish-white flowers. During May and June, the period of foliage, it is considered most dangerous to stock. H. S. Goodell affirms that he has seen violent convulsions produced by the juice of *Z. venenosus.* Slade (*A. J. P.*, 1905, p. 262) obtained an alkaloid *zygadenine* $C_{39}H_{63}O_{10}N$ from *Z. venenosus,* which resembled veratalbine. Heyle and others (*J. A. C. S.*, 1911 and 1913) obtained an alkaloid from the leaves of *Z. intermedius, zygadenine,* which resembled veratrine.

PART III

SECTION I

In this section are considered those matters included in the "General Tests, Processes and Apparatus" of the U. S. Pharmacopœia and the "Appendix" of the British Pharmacopœia which are not given elsewhere in this volume. There has also been inserted a collection of formulas for reagents used in the examination of urine, blood, etc., which is an amplification of the "Diagnostical Agents and Clinical Tests" of the U. S. IX.

Acid Number

(U. S.)

The acid number is the number of milligrammes of potassium hydroxide required to neutralize the free acid in 1 Gm. of oils, fats, waxes, resins, balsams, and similar organic substances of complex composition. It is determined as follows: Shake about 2 Gm. of the substance, accurately weighed, with from 30 to 50 cc. of neutral alcohol or with a neutral mixture of equal volumes of alcohol and ether, and titrate with half-normal potassium hydroxide, using 1 cc. of phenolphthalein T.S. as indicator.

When the quantity of free acid is small, tenth-normal potassium hydroxide should be used. In place of potassium hydroxide, half-normal or tenth-normal sodium hydroxide may be used for this test, but should be calculated to the equivalent of potassium hydroxide.

Alcohol Determination

(U. S.)

Place 25 cc. of the preparation, measured at any definite temperature between 15° and 30° C., in a distilling flask of about 200 cc. capacity, provided with a high side tube connected with a suitable condenser; add 50 cc. of distilled water, distil into a 50 cc. graduated flask, at such a rate that about 48 cc. of distillate will be received in a half hour; if volatile products other than alcohol are known to be absent, bring to the original temperature and dilute to 50 cc. with water of the same temperature.

Determine the specific gravity of the distillate at any definite temperature between 15° and 30° C. by means of a pycnometer, and find the per cent. of absolute alcohol by volume by reference to the alcoholometric table (page 1616), and multiply by the dilution factor to find the per cent. of alcohol in the original preparation.

If the preparation is thought to contain less than 25 per cent. of alcohol, 50 cc. should be used for analysis; if it is believed to contain over 50 per cent. of alcohol, 10 cc. should be taken. In either case, the volume of the distillate should be made up to 50 cc. as directed above.

If the preparation contains iodine, treat it with zinc dust before distilling. (Sodium thiosulphate may be used instead of zinc dust, in which case several drops of sodium hydroxide T.S. should be added to prevent sulphur compounds from distilling over.) If volatile acids are present, neutralize with sodium hydroxide T.S.; if volatile bases are present, neutralize with diluted sulphuric acid; if both volatile acids and volatile bases are present, neutralize with diluted sulphuric acid and distil about 50 cc., neutralize this distillate with sodium hydroxide T.S., add 25 cc. of distilled water, and distil once more in the manner directed above and dilute to 50 cc.

If camphor, chloroform, ether, volatile oils, or other volatile products are known or believed to be present, transfer the first distillate to a separatory funnel and saturate it with sodium chloride, add 15 cc. of petroleum benzin and shake the mixture for one or two minutes.

If glycerin is present, dilute the liquid with sufficient distilled water to insure not more than 50 per cent. of glycerin remaining in the liquid left in the flask after distilling. After the liquids have completely separated, draw off the lower alcoholic salt solution into a second separator, and repeat the extraction with 15 cc. of petroleum benzin; draw off the lower alcoholic salt solution into a distilling flask of about 200 cc. capacity, wash the combined petroleum benzin solutions with about 25 cc. of saturated sodium chloride solution, and add the washings to the distilling flask. Distil into a 50 cc. graduated flask at such a rate that about 45 to 48 cc. of distillate are received within a half hour. Bring to the original temperature, dilute with water of the same temperature to 50 cc., and determine the specific gravity and alcoholic per cent. as directed above.

Arsenic Test

(U. S.)

Test Apparatus.—Prepare several generators, equipped with tubes, etc., as described below. Select as a generator a bottle of about 50 cc. capacity, having a mouth about 2.5 cm. in diameter and provide a well-fitting rubber stopper, suitably perforated. Through the perforation insert a vertical exit tube about 13 cm. in total length and 1 cm. in diameter throughout the upper portion (for about 10 cm.) and constricted at its lower extremity to a tube of about 3 cm. in length and about 5 mm. in diameter. This latter tube should extend but slightly below the stopper. In the lower part of the wider exit tube insert a small pledget of dry glass wool (page 1557) and then a strip of freshly prepared but dry lead acetate test paper (page 1564) rolled into a coil, and above this a plug of moist (not wet) lead acetate glass wool (page 1564). In the upper extremity of this tube insert, through a perforated cork stopper, a glass tube 12 cm. in length, having an internal diameter of about 3 mm. Place a strip of mercuric bromide test paper in this tube, bending or creasing the upper portion of the strip so that it will retain its position. The strip should extend within about 2 cm. of the perforated cork stopper and must not be introduced into the tube until the test is ready to start. This tube should be thoroughly cleaned and dried each time it is used.

Standard Arsenic Test Solution.—Dissolve 0.1 Gm. of arsenic trioxide (page 186) which has been finely pulverized, dried over sulphuric acid, and accurately weighed, in about 5 cc. of a 20 per cent. solution of sodium hydroxide (free from arsenic). Neutralize the solution with diluted sulphuric acid (free from arsenic), add 10 cc. of the same acid and sufficient recently boiled distilled water to bring the volume of the solution to exactly 1000 cc. at 25° C. Accurately measure 10 cc. of this solution, transfer it to a 1000 cc. flask, add 10 cc. of diluted sulphuric acid (free from arsenic) and make up the volume with recently boiled distilled water to exactly 1000 cc. at 25° C. Employ this solution, which contains 0.001 milligramme of arsenic trioxide in each cc. (at 25° C.), in preparing the standard stain. Keep this solution in a glass-stoppered bottle. It is advisable to make fresh solutions when new standard stains are to be prepared.

Preparation of the Chemical to be Tested.—Add 1 cc. of a mixture of equal volumes of concentrated sulphuric acid and distilled water, to 5 cc. of an aqueous solution of the chemical (1 in 25) or to a solution in 5 cc. of distilled water of the residue remaining after any special treatment that may be directed. This acidulation is not necessary in the case of inorganic acids. Now, unless specially directed, add 10 cc. of sulphurous acid. Evaporate this liquid in a small beaker, on a water bath, until it is free from sulphurous acid and has been reduced to about 2 cc. in volume. Dilute this evaporated liquid to about 5 cc. with distilled water.

Preparation of the Standard Stain.—Introduce into the generator from 8 to 10 Gm. of reagent zinc, followed by 25 cc. of dilute sulphuric acid, prepared by mixing 1 part of concentrated sulphuric acid, free from arsenic (page 1561), with 4 parts of distilled water, and 5 drops of acid stannous chloride T.S. Add at once 2 cc. (accurately measured at 25° C.) of the standard arsenic T.S., and immediately insert the stopper containing the exit tube, into which have been placed the glass wool pledget, the dry lead acetate test paper, the moist lead acetate glass wool, and the mercuric bromide test paper, as described under *Test Apparatus* (page 1533). Should the evolution of the gas be violent at first, check the reaction by immersing the bottle in cold water. Should the reaction subside, increase it by placing the bottle in warm water. If the reaction is too violent, the stain will spread and not form a distinctive band, thus making the comparisons of color intensity difficult. After the test has continued for forty-five minutes, remove the mercuric bromide test paper and place it in a clean, dry tube for comparison. This stain represents 0.002 milligramme of arsenic trioxide in addition to any stain produced by the reagents. The stain produced by the reagents in a blank test should be scarcely perceptible. Since light, heat, and moisture cause the stain to fade rapidly, comparison should be made as soon as possible. The stained test papers may be preserved by dipping in hot, melted paraffin or by keeping them over phosphoric anhydride, protected from light.

Testing the Chemical.—Introduce into another generator from 8 to 10 Gm. of the zinc, followed by 25 cc. of the dilute sulphuric acid (1 to 4) and 5 drops of acid stannous chloride T.S. Insert the stopper containing the exit tube in which have been placed the test papers and glass wool, as just described. Then add 5 cc. of the solution to be tested, previously treated as directed under *Preparation of the Chemical to be Tested*, and immediately insert the stopper containing the exit tube. When the evolution of hydrogen has proceeded actively for forty-five minutes, remove the mercuric bromide test paper and carefully compare it with the standard stain prepared as described above. The stain produced by the chemicals tested does not exceed in length or intensity of color that prepared as the standard, indicating not more than 1 part of arsenic trioxide in 100,000 parts of the substance tested.

Interfering Chemicals.—*Antimony*, if present in the substance tested, will produce a gray stain. *Sulphites, sulphides, thiosulphates*, and other compounds which liberate hydrogen sulphide or sulphurous acid when treated with sulphuric acid, must be oxidized by means of nitric acid and then reduced by means of sulphurous acid as directed under *Preparation of the Chemical to be Tested*, before introducing them into the apparatus. *Sulphur compounds* as well as *hydrogen phosphide* give a bright yellow band on the test paper. If sulphur compounds are present, a simultaneous darkening of the lead acetate test paper and glass wool will occur. If such is the case, the operation as directed under *Preparation of the Chemical to be Tested* must be repeated upon a fresh portion of the solution being tested, using greater care in effecting the complete removal of the sulphurous acid. In testing hypophosphites special care should be observed to oxidize completely the solution being tested as directed, otherwise a yellow stain may be produced through the evolution of hydrogen phosphide, which might be confused with the orange-yellow color produced by arsenic. The stain produced by hydrogen phosphide is differentiated from that given by arsenic by moistening it with ammonia T.S. A stain caused by arsenic will become dark, but if produced by hydrogen phosphide it will not materially change in color. The test apparatus should be thoroughly cleaned and dried immediately before and after use.

Compounds containing antimony should be tested for arsenic by Bettendorf's Test (see below).

Arsenic Test, Bettendorf's

(U. S.)

This test for the presence of *arsenic* is employed only in testing salts of bismuth and compounds containing antimony.

To a solution of the prescribed quantity of the substance to be tested in 5 cc. of concentrated hydrochloric acid (page 1557) contained in a clean test tube, add 10 cc. of acid stannous chloride T.S. which has been freshly prepared, and set it aside for thirty minutes. If arsenic is present in non-permissible amounts, a brownish tint or precipitate will be seen when the tube is placed over a white surface and the solution viewed from above, comparison being made with a mixture of 5 cc. of concentrated hydrochloric acid (page 1557) and 10 cc. of concentrated stannous chloride T.S., prepared as directed above.

NOTE: It is absolutely necessary that for this test the solution of stannous chloride be freshly prepared, and that nitrates, sulphates, sulphides, sulphites, and compounds of mercury, gold, and selenium be absent from the reagents, and the chemicals being tested.

Ash or Non-Volatile Matter in Chemicals

(U. S.)

Weigh accurately from 1 to 2 Gm., or the amount of the chemical directed in the text, and place it in a tared platinum or porcelain crucible. Ignite it, at first very gently, then gradually raise the temperature until any carbon which may be formed is completely burned off. Conduct the ignition in a place protected from air currents and use as low a temperature as possible to effect the combustion of the carbon. When the carbon has completely disappeared, transfer the crucible while still hot to a desiccator, and weigh it when cold. In the case of substances which increase in volume on ignition, or where it is very difficult to burn off the carbon, the determination is facilitated by using a platinum dish of suitable size, or by igniting the weighed quantity of the substance, in the manner described above, in several separate portions.

To test for non-volatile matter in volatile inorganic chemicals, proceed as directed above, using as low a temperature as possible.

Assay for Acids (Alkalimetric)

(U. S.)

In assaying acids the quantity of acid to be taken should be such that about 30 to 40 cc. of the alkali solution will be consumed. As a general principle it is recommended that the normality of the acid to be titrated should be approximately the same as that of the titrating medium. Except when otherwise directed the liquid to be titrated is to be brought to room temperature before titration, as many indicators give different values at different temperatures. For most of the inorganic acids, methyl orange, methyl red, phenolphthalein, or litmus can be used as indicators, but the alkali must be standardized with the particular indicator used. For organic acids, phenolphthalein is always used.

Tare a glass-stoppered flask of about 150 to 200 cc. capacity, pour into it approximately the quantity of acid directed in the text, stopper immediately, and reweigh: the difference represents the quantity of acid taken. Dilute with distilled water to about 40 cc. and titrate with normal sodium hydroxide, using the indicator specified in the text.

In assaying acids which evolve fumes on exposure to air, such as hydrochloric, nitric, and glacial acetic acids, the flask is tared with 10 cc. of distilled water, then the specified quantity of acid is added, the flask immediately stoppered, allowed to cool, and reweighed. Solid acids are weighed either in a tared glass-stoppered flask or in another suitable container, dissolved in about 40 cc. of distilled water, and titrated.

Assay for Alkali Benzoates and Salicylates

(U. S.)

Dry about 2 Gm. of the salt to constant weight at from 100° to 110° C., weigh accurately in a platinum or porcelain crucible, and heat at first gently, then gradually raise the temperature until the salt is thoroughly carbonized. The final temperature must not exceed a dull red heat and the flame of the burner must not come into contact with the carbonized mass. Allow the carbonized mass to cool, disintegrate it well with a stout glass rod or powder carefully, and transfer with the crucible to a beaker or casserole. Add 50 cc. of distilled water and 50 cc. of half-normal sulphuric acid, cover the beaker or casserole with a watch glass, and boil for thirty minutes. Filter and wash the residue with hot distilled water until the washings cease to redden blue litmus paper. Dry the residue and filter paper, and ignite as described above. Transfer the ignited residue to the filtrate, and determine the excess of acid in the cooled filtrate by titration with half-normal sodium hydroxide, using methyl orange T.S. as indicator. The volume of half-normal sulphuric acid consumed, multiplied by the proper equivalent of the salt, represents the amount of the salt present in the quantity taken.

Assay for Alkali Salts of Organic Acids

(U. S.)

Heat about 2 Gm. of the salt, accurately weighed, in a platinum or porcelain crucible, heating at first very gently, then gradually raising the temperature until the salt is thoroughly carbonized. (*Caution*—Do not use platinum crucibles for lithium salts.) The final temperature must not exceed a dull red heat and the flame of the burner must not come in contact with the carbonized mass. After allowing the carbonized mass to cool, moisten with distilled water, ignite again, and repeat the moistening and igniting until a white residue is obtained. Then disintegrate the ignited mass with the aid of a stout glass rod and transfer the mass and crucible to a beaker. Add 50 cc. of distilled water and titrate with half-normal sulphuric acid, using methyl orange T.S. as indicator. The number of cc. of half-normal sulphuric acid used, multiplied by the proper equivalent of the salt, represents the amount of salt present in the quantity taken.

Assay for Chlorides, Bromides, and Iodides

(U. S.)

Chlorides.—Dissolve about 0.2 Gm. of the salt to be assayed, accurately weighed, (corresponding to from 30 to 40 cc. of tenth-normal silver nitrate), in 25 cc. of distilled water in a 200 cc. graduated flask. Add 50 cc. of tenth-normal silver nitrate to the solution, and 5 cc. of nitric acid, then add sufficient distilled water to make 200 cc., and mix well. Filter the mixture through a dry filter into a dry flask, and reject the first 20 cc. of the filtrate. To 100 cc. of the filtrate add 2 cc. of ferric ammonium sulphate T.S. and titrate with tenth-normal potassium thiocyanate until the supernatant liquid remains reddish after it is well shaken. Multiply by 2 the number of cc. of tenth-normal potassium thiocyanate required, and subtract this figure from the number of cc. of tenth-normal silver nitrate added. The difference, multiplied by the equivalent of the respective chloride, represents the amount of chloride present in the weight of the salt or solution taken.

Bromides and Iodides.—Dissolve about 0.4 Gm. of the salt if a bromide, or 0.5 Gm. of the salt if an iodide, accurately weighed, in 25 cc. of distilled water in a glass-stoppered flask. Add 50 cc. of tenth-normal silver nitrate to the solution, then 2 cc. of ferric ammonium sulphate T.S. and 2 cc. of nitric acid and determine the excess of silver nitrate by titrating with tenth-normal potassium thiocyanate until the supernatant liquid remains reddish after it is well shaken. The difference between the number of cc. of tenth-normal silver nitrate added and the number of cc. of tenth-normal potassium thiocyanate used, multiplied by the equivalent of the respective bromide or iodide being assayed, represents the amount of the bromide or iodide present in the weight of the salt taken. This difference, divided by the weight of the salt taken, represents the number of cc. of tenth-normal silver nitrate required by 1 Gm. of the salt.

Boiling and Distilling Points

(U. S.)

Method I.—For the purpose of the Pharmacopœia the boiling point is defined as that range of temperature within which at least 95 per cent., by volume, of the substance distils, when treated as directed below.

Apparatus Required.—A distilling bulb of from 50 to 60 cc. capacity to the lower part of the neck; the length of the neck is from 10 to 12 cm. and its internal diameter from 14 to 16 mm. The outlet tube of from 4 to 5 mm. internal diameter is to be attached to the neck at approximately its midpoint, forming an angle of from 70° to 75° with the lower end of the neck.

A straight glass condenser with a water jacket from 40 to 60 cm. in length; the distance from the upper end of the water jacket to the neck of the bulb being from 18 to 25 cm.

Thermometer.—In order to avoid the necessity for an emergent stem correction, it is advisable that an accurately standardized thermometer of the Anschütz type be used. If such a thermometer is not available, a thermometer used for melting points may be employed, applying the emergent stem correction as described under *Melting Points*, the length of emergent stem being measured, in degrees, from the lower end of the stopper to the highest point of the boiling temperature. When placed in position, the lower end of the thermometer is from 2 to 3.5 cm. below the center of the orifice of the outlet tube.

An asbestos board of from 12 to 15 cm. square and from 3 to 5 mm. in thickness, having a circular perforation, located centrally, for the reception of the bulb. The edge of the asbestos around the perforation should fit closely to the bulb when the latter is set into it. The size of the perforation should be such that when the bulb is set into it the portion of the bulb below the upper surface of the asbestos will have a capacity of from 3 to 4 cc.

Procedure.—Place the asbestos board on a tripod or other suitable support. Introduce into the distilling bulb 25 cc. of the liquid to be tested, insert the thermometer, stand the bulb in an upright position in the perforation of the asbestos board and connect it with the condenser. Then distil the liquid at the rate of 1 cc. for each fifteen to twenty seconds, noting the temperature as soon as 5 drops of the liquid have distilled into the receiver and when 95 per cent. of the original volume has distilled. Correct the reading for any variation in the barometric pressure from the normal (760 mm.) by allowing 0.1° C. for each 2.7 mm., adding if the pressure is lower, and subtracting if higher.

Note: In order to have the entire volatile portion distil over at the prescribed rate, it is best to make a preliminary distillation of a separate portion of 25 cc. of the liquid, during which the source of heat (a Bunsen burner) is regulated so that the distillation proceeds at the prescribed rate. Having thus regulated the burner, temporarily remove it, clean the bulb, recharge it with a fresh portion of 25 cc. of the liquid, and conduct a new distillation as described above.

Method II.—This method is to be used with liquids for which the permissible range in boiling temperature exceeds 5° C.

Apparatus Required.—A 200 cc. distilling bulb with an outlet tube at approximately the center of the neck, forming an angle of from 70° to 75°, with the lower end of the neck. The length of the neck is from 10 to 12 cm. and its inside diameter is from 18 to 24 mm. The length of the outlet tube is from 10 to 12 cm. and its inside diameter is from 5 to 6 mm. A straight glass condenser, a thermometer, and an asbestos board as in Method I. The diameter of the perforation in the asbestos board is 25 mm.

Procedure.—Place the distilling bulb in an upright position in the perforation in the asbestos board and connect it with the condenser. The outlet tube is to extend from 25 to 35 mm. into the condenser beyond the connecting stopper. Measure 100 cc. of the liquid[1] to be tested, using a cylinder having 1 cc. graduations. Note the temperature of the liquid and transfer it as completely as possible to the distilling bulb. Use this cylinder as the receiver for the distillate without rinsing out any of the adhering liquid. Insert the thermometer through a stopper in the position described in Method I and heat with a Bunsen burner protected from drafts until the liquid begins to boil, then distil at the rate of from 4 to 5 cc. per minute. The temperature when 5 drops of the liquid have distilled into the receiver is the minimum distillation temperature and, unless otherwise specified, the maximum distillation temperature is the temperature at which 95 per cent. of the liquid has distilled over. Bring the distillate to the same temperature at which the liquid was originally measured, and note the volume. Correct the temperature reading for barometric pressure and apply the emergent stem correction as described in Method I.

Liquids which begin to distil below 80° C. are cooled to 10° or 15° C. before measuring the 100 cc. for the test. The end of the condensing tube is fitted with an adapter bent at a suitable angle and the end of the adapter is passed through a cork inserted into the receiving cylinder. The cork has a small perforation to permit the exit of air. The receiving cylinder is kept immersed in ice to within 2.5 cm. of its height during the distillation.

Congealing Points

(U. S.)

Unless otherwise directed, about 10 cc. of the liquid to be tested is introduced into a dry test tube of from 18 to 20 mm. internal diameter, which is then cooled in water or a suitable freezing mixture, the temperature of which should be about 5° lower than the supposed congealing point of the liquid. To induce crystallization, rub the walls of the tube with a standard thermometer (page1549), or add a small crystal of the substance being tested. By alternated immersion of the tube in the bath, or removal from the bath and constant stirring with the thermometer, the temperature is so adjusted that the greater part of the liquid gradually congeals. The highest temperature remaining constant for a short time during the congelation is defined as the congealing point.

---

[1] For the determination of the distillation range of the creosote from creosote carbonate and of the cresol from compound solution of cresol, use the volume of the creosote or of the cresol obtained as described under the respective monographs.

Electrolytic Determinations

(U. S.)

Copper, Mercury, Silver, and Zinc.—The electrolytic apparatus consists principally of an ammeter, voltmeter, and rheostat, properly connected with the source of the current, a platinum spiral or disc anode, and a device for rotating the anode. Other suitable apparatus adapted to the use of rotating electrodes may also be employed. The source of the current may be either storage batteries or any other system of direct current which permits regulation of the voltage and amperage. Copper and silver are determined in a platinum dish of about 100 cc. capacity which serves as the cathode. Mercury is determined in a mercury cathode cup, or in a platinum dish which serves as the cathode. The mercury cathode cup consists of a glass cylinder about 6.5 cm. in height and 3.5 cm. in diameter, into which is fused a platinum wire near the bottom, and containing from 50 to 60 Gm. of mercury. The platinum wire must be in contact with the mercury. For the determination of zinc, a nickel dish of about 175 cc. capacity is used. A platinum dish upon which a thin layer of silver or copper has been previously deposited may also be used.

Cupric Sulphate.—Dissolve from 0.75 to 1.0 Gm. of the salt, accurately weighed, in about 100 cc. of distilled water in a weighed platinum dish, add 1 cc. of diluted sulphuric acid, rotate the anode about 500 revolutions per minute and pass the current, gradually increasing it to 2.5 amperes and from 5 to 7 volts. Occasionally add a little distilled water to the electrolyte to keep the deposit of copper covered. When the copper is all deposited (usually in about twenty minutes, to be ascertained by withdrawing a little of the electrolyte and testing it with hydrogen sulphide T.S.), stop the rotation, and wash the deposit with distilled water by means of a siphon without interrupting the current, until the current drops to nearly zero. Remove the dish, wash again with distilled water by decantation, followed by a little alcohol and ether, successively, dry for a few minutes only, at from 80° to 100° C., and weigh.

One gramme of Copper is the equivalent of:

	Gramme
Cupric Sulphate, $CuSO_4.5H_2O$	3.9281
Cupric Sulphate, anhydrous, $CuSO_4$	2.5112

Corrosive Mercuric Chloride.—Dissolve from 0.3 to 0.4 Gm. of the salt, accurately weighed, in 10 cc. of distilled water and transfer the solution to the cathode cup, which has been previously weighed with its metallic mercury. Dilute the liquid to about 20 cc. with distilled water, add 1 cc. of nitric acid, which has been diluted with an equal volume of distilled water, and 10 cc. of toluene, and pass through the solution a current of from 1 to 3 amperes and from 8 to 12 volts, stirring the solution by rotating the anode from 500 to 600 revolutions per minute. After twenty minutes, when the mercury is all removed from solution, (to be ascertained by removing a few drops of the solution and testing with hydrogen sulphide T.S.), wash with distilled water, with the aid of a siphon and without interrupting the current, until the current drops to nearly zero. Remove the cathode cup, wash the mercury with alcohol, then with ether, remove most of theremaining ether with filter paper, dry over sulphuric acid, and weigh. The increase in weight of the cathode cup represents the amount of mercury present in the quantity of the salt taken.

Mercury (Metallic), Mercuric Oxide (Red or Yellow), Mercury with Chalk, and Solution of Mercuric Nitrate.—Dissolve an accurately weighed quantity of the substance in a mixture of equal volumes of nitric acid and distilled water (metallic mercury or mercuric oxide from 0.2 to 0.3 Gm. in 1 cc.; mercury with chalk from 0.6 to 0.8 Gm. in 2.5 cc.), transfer the solution to the cathode cup, which has previously been weighed with its metallic mercury, and dilute with distilled water to about 30 cc. Electrolyze the solution and proceed further as described under *Corrosive Mercuric Chloride* using a current of from 1.5 to 2 amperes and from 7 to 10 volts.

Ammoniated Mercury, Mild Mercurous Chloride, Mercuric Salicylate, Red Mercuric Iodide, Yellow Mercurous Iodide.—Introduce the accurately weighed substance (from 0.5 to 0.6 Gm. of ammoniated mercury or mild mercurous chloride; from 0.7 to 0.8 Gm. of mercuric salicylate or yellow mercurous iodide; from 1.0 to 1.2 Gm. of red mercuric iodide) into the cathode cup, previously weighed with its metallic mercury, add 10 cc. of solution of sodium sulphide (made by dissolving 50 Gm. of crystallized sodium sulphide in sufficient distilled water to measure 100 cc.), and dissolve as completely as possible by agitation. Dilute the mixture to about 30 cc. with distilled water and pass through the solution a current of from 2 to 3 amperes and from 7 to 10 volts for thirty minutes (or until a few drops of the liquid do not give a black precipitate or coloration when gently warmed with a few drops of concentrated ammonium chloride solution), stirring the solution by rotating the anode about 500 revolutions per minute. Wash the mercury, and proceed as described under *Corrosive Mercuric Chloride*, except that before washing with alcohol allow it to stand with about 20 cc. of dilute acetic acid (from 2 to 3 per cent.) until bubbles cease to be evolved.

One gramme of Mercury is the equivalent of:

	Gramme
Ammoniated Mercury, $HgNH_2Cl$	1.2566
Mercuric Chloride, Corrosive, $HgCl_2$	1.3535
Mercurous Chloride, Mild, HgCl	1.1768
Mercuric Iodide, Red, HgI_2	2.2654
Mercurous Iodide, Yellow, HgI	1.6327
Mercuric Nitrate, $Hg(NO_3)_2$	1.6182
Mercuric Oxide (Red or Yellow), HgO	1.0798
Mercuric Salicylate, $HgC_7H_4O_3$	1.1798

Silver Nitrate.—Powder the salt, dry it to constant weight over sulphuric acid in the dark, dissolve from 0.3 to 0.5 Gm., accurately weighed, in about 35 cc. of distilled water in a tared platinum dish, add a solution of 2 Gm. of sodium cyanide in 10 cc. of distilled water, rotate the anode about 500 revolutions per minute, and pass a current, gradually increased to 2.5 amperes and from 5 to 7 volts. After the silver is all deposited (usually from twenty to thirty minutes, to be ascertained by withdrawing a small quantity of the electrolyte and testing it with hydrochloric acid), interrupt the current, wash the deposit of silver several times with distilled water, rinse with a little alcohol, then with ether, dry the dish at from 80° to 100° C. for a few minutes, and weigh.

Moulded Silver Nitrate.—Dissolve from 0.3 to 0.5 Gm., accurately weighed, in 10 cc. of distilled water, filter through a small filter paper, wash the paper with distilled water until free from silver nitrate, bring the combined filtrate and washings to a volume of about 35 cc. in a tared platinum dish, add a solution of 2 Gm. of sodium cyanide in 10 cc. of distilled water, and proceed with the determination as under *Silver Nitrate.*

One gramme of Silver is the equivalent of:

	Gramme
Silver Nitrate, $AgNO_3$	1.5748
Silver Oxide, Ag_2O	1.0742

Zinc (Metallic), Zinc Acetate, Zinc Carbonate, Zinc Chloride, Zinc Oxide, Zinc Phenolsulphonate, Zinc Sulphate.—Introduce into a tared nickel dish, an accurately weighed quantity of the salt, equivalent to about 0.15 Gm. of metallic zinc (zinc acetate, 0.5 Gm., zinc carbonate, 0.25 Gm.; zinc chloride, 0.3 Gm., zinc oxide, 0.2 Gm.; zinc phenolsulphonate, 1.2 Gm.; zinc sulphate, 0.6 Gm.); dissolve it in distilled water or in 10 cc. of diluted sulphuric acid (zinc carbonate, zinc oxide), add from 30 to 35 cc. of sodium hydroxide solution (20 per cent.), and dilute with distilled water to about 120 cc. Heat the mixture nearly to boiling and electrolyze for thirty minutes with a current of from 4 to 5 amperes and from 5 to 6 volts, stirring the solution by rotating the anode from 500 to 600 revolutions per minute. Without interrupting the current, wash the deposited zinc with distilled water with the aid of a siphon until the current drops to zero or nearly so. Remove the dish, wash the zinc first with alcohol then with ether, dry over sulphuric acid, and weigh. The increase in weight of the dish represents the amount of zinc present in the weight of the salt taken.

To determine zinc in metallic zinc, weigh accurately about 1.5 Gm. of the metal, dissolve it by warming with 40 cc. of diluted sulphuric acid, filter the solution, if necessary, wash the filter well with distilled water, and make up the volume of the solution and washings to 100 cc. Measure 10 cc. of this liquid into the weighed dish and proceed as directed above.

One gramme of Zinc is the equivalent of:

	Gramme
Zinc Acetate, $Zn(C_2H_3O_2)_2.2H_2O$	3.3570
Zinc Chloride, $ZnCl_2$	2.0849
Zinc Oxide, ZnO	1.2448
Zinc Phenolsulphonate, $Zn(C_6H_5SO_4)_2.8H_2O$	8.5011
Zinc Sulphate, $ZnSO_4.7H_2O$	4.3988
Zinc Sulphate, anhydrous, $ZnSO_4$	2.4695

Ester Number

(U. S.)

The ester number is the number of milligrammes of potassium hydroxide required to saponify the esters in 1 Gm. of oils, fats, waxes, resins, balsams, and similar organic substances of complex composition. If the saponification value and the acid number have been determined, the difference between these two represents the ester number.

The ester number is also determined directly as follows: Shake from 1.5 to 2 Gm. of the substance, accurately weighed in a 200 to 250 cc. tared flask, with from 20 to 30 cc. of alcohol, add 1 cc. of phenolphthalein T.S., and titrate with half-normal alcoholic potassium hydroxide until the free acid is neutralized. Add exactly 25 cc. of half-normal alcoholic potassium hydroxide, and proceed as directed under *Saponification Value*, beginning with "Insert in the neck of the flask" and omitting the further addition of phenolphthalein T.S. The difference in the number of cc. of half-normal hydrochloric acid consumed in the actual test and in the blank, multiplied by 28.06 and divided by the weight of the substance taken, gives the ester number.

Gasometric Estimations

(U. S.)

In certain cases the Pharmacopœia directs the strength of a product or chemical substance to be determined by the volume of gas (nitrogen dioxide) given off during a definite reaction. This volume is to be determined by the use of a nitrometer in the following manner:

By means of clamps attached to a stand, arrange a nitrometer consisting of a measuring tube (having a capacity of at least 50 cc. and graduated into one-tenth cc.) connected by stout rubber tubing with an open equilibrium tube (both tubes, preferably, provided with a globular expansion near the lower end) in such a manner, that either tube may be readily adjusted and quickly clamped at a higher or lower level. The stop-cock of the measuring tube having been opened, and the open equilibrium tube having been raised to a higher level, pour into the latter a saturated aqueous solution of sodium chloride, until the measuring tube, including the bore of the stop-cock, is completely filled. Then close the latter and adjust the equilibrium tube at a low level. Having ascertained that the stop-cock is closed and is air tight, and having, if necessary, wiped out the graduated tube of the nitrometer, introduce into it the prescribed quantity of the liquid to be tested, and allow this to flow slowly into the measuring tube, being careful not to admit any air. Follow it successively, with the prescribed quantities of potassium iodide T.S. and normal sulphuric acid. When the reaction moderates, remove the measuring tube from its clamp, and, being careful to hold it constantly so that the liquid contained in it stands at a higher level than that in the equilibrium tube, shake its contents without permitting any gas to pass into the open tube. When the reaction has completely ceased and the volume of gas has become constant, which usually requires from thirty to sixty minutes, restore the tube to its fastening and allow the apparatus and contents to acquire the ordinary temperature of the room, which is assumed to be close to 25° C. Then adjust the two tubes so that the liquid columns are at exactly the same level, and read the volume of gas in the measuring tube. Multiply this figure by the weight of the liquid being assayed which is the equivalent of 1 cc. of nitrogen dioxide (see below). The result will be the weight of the absolute substance (ethyl, amyl, or sodium nitrite) contained in the quantity taken for the assay.

For pharmacopœial purposes, the determination will be sufficiently exact if the evolved gas is measured within 3° above or below 25° C.

Since temperature and barometric pressure affect the volume of the gas, the following correction factors must be used to obtain exact results when the temperature and pressure vary from the normal. The barometric correction is important at any locality more than 250 meters above sea level:

FACTORS FOR TEMPERATURE CORRECTIONS
(Normal Temperature, 25° C.)

Temperature	Factor	Temperature	Factor	Temperature	Factor
15° C.	1.035	22° C.	1.010	29° C.	0.987
16° C.	1.031	23° C.	1.007	30° C.	0.983
17° C.	1.028	24° C.	1.003	31° C.	0.980
18° C.	1.024	25° C.	1.000	32° C.	0.977
19° C.	1.021	26° C.	0.997	33° C.	0.974
20° C.	1.017	27° C.	0.993	34° C.	0.971
21° C.	1.014	28° C.	0.990	35° C.	0.968

Example: Assuming that the volume of gas read off was 44.5 cc. at 32° C., and it is desired to ascertain the corresponding volume at 25° C., barometric pressure not being taken into consideration, then the 44.5 cc. must be reduced in the proportion of 1 to 0.977 (see temperature correction factors above), or 44.5 must be multiplied by 0.977. The result will be 43.48 cc. as the equivalent volume of gas at 25° C.

FACTORS FOR CORRECTION FOR BAROMETRIC PRESSURE
(Normal Barometer, 760 mm.)

Barometer Reading		Factor	Barometer Reading		Factor
Millimeters	Inches		Millimeters	Inches	
790	31.10	1.039	660	25.98	0.868
780	30.71	1.026	650	25.59	0.855
770	30.31	1.013	640	25.20	0.842
760	29.92	1.000	630	24.80	0.829
750	29.53	0.987	620	24.41	0.816
740	29.13	0.974	610	24.02	0.803
730	28.74	0.961	600	23.62	0.789
720	28.35	0.947	590	23.23	0.776
710	27.95	0.934	580	22.83	0.763
700	27.56	0.921	570	22.44	0.750
690	27.17	0.908	560	22.05	0.737
680	26.77	0.895	550	21.65	0.724
670	26.38	0.882	540	21.26	0.711

Example: Assuming that the volume of gas read off was 43.48 cc. at 590 mm. barometric pressure, and it is desired to ascertain the corresponding volume at normal barometric pressure (760 mm.), temperature not being taken into consideration, then the 43.48 cc. must be reduced in the proportion of 1 to 0.776 (see barometric correction factors above), or 43.48 must be multiplied by 0.776. The result will be 33.74 cc. as the equivalent volume of gas at normal barometric pressure.

FACTORS FOR DETERMINING NITRITES

$$NO = 30.01;\ 1\text{ Liter} \begin{cases} \text{at } 0^\circ\text{ C. and 760 mm.} = 1.3406\text{ Gm.} \\ \text{at } 25^\circ\text{ C. and 760 mm.} = 1.2281\text{ Gm.} \end{cases}$$

One cubic centimeter of Nitrogen Dioxide is the equivalent of:

		At 0° C. and 760 mm. Gramme	At 25° C. and 760 mm. Gramme
Nitrogen Dioxide, NO	= 30.01	0.0013406	0.0012281
Amyl Nitrite, $C_5H_{11}NO_2$	= 117.10	0.0052310	0.0047920
Ethyl Nitrite, $C_2H_5NO_2$	= 75.05	0.0033528	0.0030713
Sodium Nitrite, $NaNO_2$	= 69.01	0.0030828	0.0028241

Heavy Metals Test

(U. S.)

Chemicals.—This test is to be used to detect the presence of undesirable metallic impurities in official chemical substances or their solutions. Acidulate 10 cc. of a solution of the substance in distilled water (1 in 50), contained in a test tube of about 25 cc. capacity and about 2 cm. in diameter, with 1 cc. of diluted hydrochloric acid (unless otherwise directed),[1] warm it to about 50° C., add an equal volume of freshly prepared hydrogen sulphide T.S., stopper, and allow the mixture to stand at 35° C. for half an hour. At the end of this time the mixture should still possess the odor of hydrogen sulphide; if not, it should be thoroughly saturated with the gas and again set aside for half an hour. The color produced, if any, is not greater than that observed in a blank test made in the same manner and with the same quantities of the reagents (omitting the solution to be tested), the solutions being viewed crosswise by reflected light while held against a white surface. A slight turbidity due to separation of sulphur from the hydrogen sulphide may occur. Filter the solution if necessary and render it alkaline by the addition of ammonia T.S.: a greenish color may be produced but no precipitate is formed within one minute. The addition of ammonia T.S. is omitted in testing salts which produce precipitates when ammonia is added to their solutions.

Volatile Oils.—Shake 10 cc. of the oil with an equal volume of distilled water to which a drop of hydrochloric acid has been added, and pass hydrogen sulphide through the mixture until it is saturated: no darkening in color is produced in either the oil or the water (*lead* or *copper*).

Identification Tests for Chemicals

(U. S.)

Under this head are placed tests which are frequently referred to throughout the Pharmacopœia. In order to save space they are here grouped together and in the text are referred to by title and page number.

These tests are to be used for the identification of official chemicals. They are not intended to be applicable to mixtures of substances unless specific directions are given for such use.

Acetates.—When warmed with concentrated sulphuric acid, acetates evolve acetic acid. If acetic acid or an acetate is warmed with sulphuric acid and alcohol, the characteristic fragrant odor of ethyl acetate is evolved. With neutral solutions of acetates, ferric chloride T.S. produces a deep red color which is destroyed by the addition of mineral acids.

Aluminum.—Solutions of aluminum salts yield with ammonia T.S. a white precipitate which is insoluble in a moderate excess of ammonium hydroxide. Sodium hydroxide T.S. or sodium sulphide T.S. produces a similar precipitate which dissolves in an excess of either of these reagents.

Ammonium.—Ammonium salts are decomposed by the addition of an excess of sodium hydroxide T.S., with the evolution of ammonia, recognizable by its odor and by its alkaline effect upon moistened red litmus paper, exposed to the vapor.

Arsenates.—Soluble arsenates yield with silver nitrate T.S. a dark red precipitate which is soluble in diluted nitric acid. When hydrogen sulphide is passed into a solution of an arsenate containing hydrochloric acid, a yellow precipitate is slowly formed. This precipitate is soluble in ammonium sulphide T.S. Soluble arsenates yield a white precipitate with magnesia mixture T.S.

Arsenous Compounds.—Solutions of arsenous compounds, to which hydrochloric acid has been added, yield with hydrogen sulphide a yellow precipitate which is insoluble in strong hydrochloric acid but soluble in ammonium carbonate T.S.

Barium.—Solutions of barium salts yield a white precipitate with diluted sulphuric acid. This precipitate is insoluble in hydrochloric or nitric acid. Barium salts impart a green color to a non-luminous flame.

Benzoates.—In neutral solutions, benzoates yield a salmon-colored precipitate with ferric chloride T.S. In moderately concentrated aqueous solutions, benzoates yield a precipitate of benzoic acid upon acidulation with diluted sulphuric acid. This precipitate is readily soluble in ether.

Bicarbonates.—(See *Carbonates*).

Bismuth.—When dissolved in a slight excess of nitric or hydrochloric acid, bismuth salts yield a white precipitate upon dilution with water. This precipitate is blackened by hydrogen sulphide, and the resulting compound dissolves in a warm mixture of equal parts of nitric acid and water.

Bisulphites.—(See *Sulphites*).

Borates.—Solutions of borates, acidulated with hydrochloric acid, turn turmeric paper brownish-red, the color changing to greenish-black by moistening with ammonia T.S. When a borate is treated with sulphuric acid, alcohol added, and the mixture ignited, it burns with a green bordered flame.

Bromates.—Sulphurous acid added drop by drop to a solution of a bromate produces a yellow color, which disappears upon the addition of an excess of sulphurous acid. Bromates, when gently ignited with charcoal, yield bromides which may be recognized by the characteristic reactions.

Bromides.—In solutions of bromides, the addition of chlorine T.S., drop by drop, liberates bromine which is dissolved by shaking with chloroform, coloring the chloroform red to reddish-brown. Silver nitrate T.S. produces in solutions of bromides a yellowish precipitate which is insoluble in nitric acid, and only slightly soluble in dilute ammonia T.S.

Cadmium.—Neutral, alkaline, or moderately acid solutions of cadmium salts yield a yellow precipitate with hydrogen sulphide. This precipitate is insoluble in alkali hydroxides, in alkali sulphides, and in cold dilute acids, but it is soluble in cold, moderately dilute nitric acid, in hot dilute hydrochloric acid, or in hot moderately dilute sulphuric acid.

Calcium.—In neutral or alkaline solutions, or in solutions of calcium salts free from mineral acid, ammonium oxalate T.S. produces a white precipitate. This precipitate is insoluble in acetic acid, but dissolves in hydrochloric acid. Calcium salts moistened with hydrochloric acid impart a yellowish-red color to a non-luminous flame.

Carbonates.—Carbonates or bicarbonates effervesce with acids, yielding a colorless gas, which when passed into calcium hydroxide T.S. produces a white precipitate. Carbonates in solution produce a reddish-brown precipitate with mercuric chloride T.S., while bicarbonates produce a white precipitate with the same reagent. A cold aqueous solution of a carbonate is reddened by phenolphthalein T.S., while a similar solution of a bicarbonate remains unchanged or is only slightly reddened.

Chlorates.—Solutions of chlorates yield no precipitate with silver nitrate T.S. The addition of sulphurous acid to this mixture produces a white precipitate which is insoluble in nitric acid but soluble in ammonia T.S. Upon ignition, chlorates yield chlorides, recognizable by appropriate tests. When concentrated sulphuric acid is added to a dry chlorate, decrepitation occurs and a greenish-yellow gas is evolved. *Caution.*—Only a small amount of chlorate should be used for this test and extreme caution must be exercised in performing it.

---

[1] Acids are first carefully neutralized by the addition of ammonia T.S. and then acidified as directed above.

Chlorides.—Solutions of chlorides yield a white, curdy precipitate with silver nitrate T.S. This precipitate is insoluble in nitric acid, but is easily and completely dissolved by a slight excess of ammonia T.S.

Chromates.—Solutions of chromates or dichromates, free from mineral acids, yield with lead acetate T.S. a yellow precipitate, which is insoluble in acetic acid. When a chromate or a dichromate is acidulated with diluted sulphuric acid and hydrogen dioxide T.S. added, a blue color is produced. Upon shaking with ether, the blue color passes into the ethereal layer.

Citrates.—Neutral solutions of citrates are not affected in the cold by the addition of an excess of calcium chloride T.S., but, upon heating the mixture, a white precipitate is produced. When to a hot solution of a citrate, to which has been added one-tenth of its volume of mercuric sulphate T.S., potassium permanganate T.S. is added, a white precipitate is produced.

Cobalt.—Solutions of cobaltous compounds yield a blue precipitate with sodium hydroxide T.S. This precipitate rapidly changes color, becoming olive-green, and, if boiled soon after its formation, becomes rose-red. Solutions of cobalt salts, when treated with an excess of potassium nitrite and acetic acid, yield a yellow precipitate.

Copper.—Solutions of copper compounds, acidulated with hydrochloric acid, deposit a red film of metallic copper upon a bright untarnished surface of metallic iron. An excess of ammonia T.S., added to a solution of a copper salt, produces a blue color. With potassium ferrocyanide T.S., solutions of cupric salts yield a red precipitate.

Cyanides.—Solutions of cyanides yield a white, curdy precipitate with an excess of silver nitrate T.S. This precipitate is soluble in an excess of a solution of a soluble cyanide, or ammonia T.S., also soluble in boiling nitric acid. To 10 cc. of a weak solution of a cyanide, add a few drops of freshly prepared ferrous sulphate T.S., 1 cc. of sodium hydroxide T.S., a few drops of ferric chloride T.S., warm, and finally add an excess of diluted sulphuric acid: a blue precipitate is produced.

Dichromates.—(See *Chromates*).

Ferricyanides.—Solutions of ferricyanides yield a blue precipitate with ferrous sulphate T.S. This precipitate is insoluble in diluted hydrochloric acid, but is decomposed by sodium hydroxide T.S.

Ferrocyanides.—Solutions of ferrocyanides yield a blue precipitate with ferric chloride T.S. With copper sulphate T.S., ferrocyanides yield a red precipitate.

Glycerophosphates.—Solutions of glycerophosphates yield no precipitate in the cold with ammonium molybdate T.S., but upon boiling, an abundant yellow precipitate is formed. Moderately diluted solutions of glycerophosphates, when treated with calcium chloride T.S., remain unaffected in the cold, but on boiling, a precipitate is produced which redissolves on cooling.

Gold.—Solutions of gold salts yield a purple coloration or precipitate with stannous chloride T.S.

Hypophosphites.—When strongly heated, hypophosphites evolve spontaneously inflammable hydrogen phosphide. Hypophosphites in solution yield a white precipitate with mercuric chloride T.S. This precipitate becomes gray when an excess of hypophosphite is present. Solutions of hypophosphites, acidulated with sulphuric acid and warmed with copper sulphate T.S., yield a red precipitate.

Iodides.—In solutions of iodides, the addition of chlorine T.S., drop by drop, liberates free iodine which colors the solution yellow to red, and on shaking with chloroform the latter is colored violet. The iodine thus liberated gives a blue color with starch. Silver nitrate T.S. produces in solutions of iodides a yellow, curdy precipitate which is insoluble in nitric acid and in ammonia T.S.

Iron.—Ferrous or ferric compounds in solution yield a black precipitate with ammonium sulphide T.S. This precipitate is dissolved by cold diluted hydrochloric acid with the evolution of hydrogen sulphide.

Ferric salts in solution yield a dark blue precipitate with potassium ferrocyanide T.S. With an excess of sodium hydroxide T.S., a reddish-brown precipitate is formed. Solutions of ferric salts produce with potassium thiocyanate T.S. a deep red color which is not destroyed by diluted mineral acids.

Ferrous salts in solution yield a dark blue precipitate with potassium ferricyanide T.S. This precipitate is insoluble in diluted hydrochloric acid, but is decomposed by sodium hydroxide T.S. Solutions of ferrous salts yield with sodium hydroxide T.S. a white precipitate, the color rapidly changing to green.

Lactates.—Solutions of lactates, when acidulated with sulphuric acid, potassium permanganate T.S. added, and the mixture heated, evolve acetaldehyde which is recognizable by its odor.

Lead.—Solutions of lead salts yield with diluted sulphuric acid a white precipitate which is slightly soluble in diluted hydrochloric or nitric acid, but completely soluble in warm sodium hydroxide T.S. With potassium chromate T.S. solutions of lead salts, free or nearly free from mineral acids, yield a yellow precipitate which is insoluble in acetic acid but soluble in sodium hydroxide T.S.

Lithium.—Lithium salts moistened with hydrochloric acid impart an intense crimson color to a non-luminous flame. Solutions of lithium salts are not precipitated by diluted sulphuric acid or soluble sulphates (*difference from Strontium*).

Magnesium.—Solutions of magnesium salts in the presence of ammonium chloride yield no precipitate with ammonium carbonate T.S., but on the subsequent addition of sodium phosphate T.S. a white precipitate is produced which is insoluble in ammonia T.S.

Manganous Compounds.—When in solution manganous compounds yield a salmon-colored precipitate with ammonium sulphide T.S. This precipitate is dissolved by acetic acid.

Mercury.—Solutions of mercury salts free from excess of nitric acid, when applied to bright copper foil, yield a deposit, which, upon rubbing, becomes bright and silvery in appearance. With an excess of hydrogen sulphide, mercury compounds yield a black precipitate which is insoluble in ammonium sulphide T.S., or in boiling diluted nitric acid.

Mercuric compounds in solution yield a yellow precipitate with sodium hydroxide T.S. They also yield in neutral solutions a scarlet precipitate with potassium iodide T.S. This precipitate is very soluble in an excess of potassium iodide T.S.

Mercurous compounds are blackened by ammonia T.S. or sodium hydroxide T.S. Solutions of mercurous salts yield with hydrocc ihlroacid a white precipitate which is blackened by ammonia T.S. With potassium iodide T.S., a yellow precipitate is produced.

Molybdates.—When a dry molybdenum compound is covered with sulphuric acid and heated until the acid is almost all driven off, a blue residue remains. Solutions of molybdates acidulated with nitric acid, yield a yellow precipitate on warming with sodium phosphate T.S. This precipitate is soluble in ammonia T.S.

Nitrates.—When a solution of a nitrate is mixed with an equal volume of sulphuric acid, the mixture cooled, and a solution of ferrous sulphate superimposed, a brown color is produced at the junction of the two liquids. When a nitrate is heated with sulphuric acid and metallic copper, brownish-red fumes are evolved.

Nitrites.—When treated with diluted mineral acids or with acetic acid, nitrites yield brownish-red fumes. On adding a few drops of potassium iodide T.S. and a few drops of dilute sulphuric acid to a solution of a nitrite, iodine is liberated which colors starch T.S. blue.

Nitroprussides.—The addition of a dilute solution of a soluble sulphide to a solution of a nitroprusside produces a transient purple to deep violet color, the intensity and shade of color depending upon the concentration of the solutions.

Oxalates.—Neutral or alkaline solutions of oxalates yield a white precipitate with calcium chloride T.S. This precipitate is insoluble in acetic acid but is dissolved by hydrochloric acid.

Palladium.—When in solution palladous salts yield with ammonia T.S. a salmon-colored precipitate, which is soluble in an excess of the reagent. Hydrochloric acid added to this solution produces a yellow precipitate.

Permanganates.—Solutions of permanganates acidulated with sulphuric acid are decolorized by hydrogen dioxide T.S., sodium bisulphite T.S., or oxalic acid T.S.

Peroxides.—Solutions of peroxides slightly acidulated with sulphuric acid yield a deep blue color upon the addition of potassium dichromate T.S. On shaking the liquid with an equal volume of ether, the blue color passes into the ethereal layer.

Phosphates.—Neutral solutions of orthophosphates yield with silver nitrate T.S. a yellow precipitate, which is soluble in diluted nitric acid or in ammonia T.S. With ammonium molybdate T.S., a yellow precipitate is produced which is soluble in ammonia T.S.

Phosphotungstates.—(See *Tungstates*).

Potassium.—Potassium compounds impart a violet color to a non-luminous flame, but the presence of small quantities of sodium masks the color. In neutral, concentrated or moderately concentrated solutions of potassium salts (depending upon the solubility and the potassium content of the salt), sodium bitartrate T.S. produces a white crystalline precipitate which is soluble in ammonia T.S., alkali hydroxides or carbonates. The formation of the precipitate, which is usually slow, is accelerated by stirring or rubbing the sides of the test tube with a glass rod. The addition of a little glacial acetic acid also promotes the formation of the precipitate.

Salicylates.—In moderately dilute solutions of salicylates, ferric chloride T.S. produces a violet color. The addition of acids to moderately concentrated solutions of salicylates produces a precipitate of salicylic acid.

Selenium.—Stannous chloride T.S. produces a red color in solutions of *selenates*. Solutions of *selenites* yield a red color with sodium bisulphite.

Silver.—Solutions of silver salts yield with hydrochloric acid a white, curdy precipitate which is insoluble in nitric acid but is easily soluble in ammonia T.S.

Sodium.—Sodium compounds impart an intense yellow color to a non-luminous flame.

Strontium.—Strontium compounds, moistened with hydrochloric acid, impart a crimson color to a non-luminous flame. Calcium sulphate T.S. produces a white precipitate with solutions of strontium salts.

Sulphates.—Solutions of sulphates yield with barium chloride T.S. a white precipitate, which is insoluble in hydrochloric or nitric acid.

Sulphides.—When treated with an acid, many sulphides yield hydrogen sulphide, recognizable by its characteristic odor and by its blackening moist lead acetate test paper.

Sulphites.—When treated with hydrochloric acid, sulphites, and bisulphites yield colorless sulphur dioxide, recognizable by its pungent odor which resembles burning sulphur. This gas blackens filter paper moistened with mercurous nitrate T.S.

Tartrates.—With neutral solutions of tartrates, silver nitrate T.S. produces a white precipitate. Upon dissolving this precipitate in just sufficient ammonia T.S. and warming, metallic silver is deposited on the sides of the test tube, forming a mirror. When a drop of ferrous sulphate T.S., then a few drops of hydrogen dioxide T.S., and finally an excess of sodium hydroxide T.S. are added to a solution of tartaric acid or of a tartrate, acidified with acetic acid, a purple or violet color is produced.

Thiocyanates.—Solutions of thiocyanates yield a red color with ferric chloride T.S. which is not destroyed by moderately concentrated mineral acids.

Thiosulphates.—Solutions of thiosulphates yield with hydrochloric acid a white precipitate of sulphur which soon turns yellow, sulphur dioxide being liberated, recognizable by its odor. The addition of ferric chloride T.S. to solutions of thiosulphates, produces a dark violet color which quickly disappears.

Tin.—When metallic zinc is placed in a solution of a salt of tin acidified with hydrochloric acid, the tin is precipitated in metallic form. The precipitated metal is soluble in boiling hydrochloric acid and the resulting solution yields a white or gray precipitate with mercuric chloride T.S.

Tungstates.—Solutions of tungstates or phosphotungstates yield with stannous chloride T.S. a yellow precipitate, which, upon heating with hydrochloric acid, changes to blue. Solutions of tungstates, when evaporated to dryness with hydrochloric acid, leave a yellow residue of tungstic oxide which is soluble in ammonia T.S.

Vanadates.—Solutions of vanadates yield a yellow precipitate with potassium ferrocyanide T.S.

Zinc.—In alkaline solutions, zinc salts yield a white precipitate with hydrogen sulphide. This precipitate is insoluble in acetic acid but is dissolved by diluted hydrochloric acid. Ammonium sulphide produces a similar precipitate in neutral or alkaline solutions. Zinc salts in solution yield with potassium ferrocyanide T.S. a white precipitate which is insoluble in diluted hydrochloric acid.

Iodine Value

(U. S.)

The iodine value or number of a fat or oil indicates the proportion of iodine absorbed under specified conditions. It is determined as follows: Introduce about 0.8 Gm. of a solid fat or about 0.3 Gm.[1] of an oil, accurately weighed, into a glass-stoppered bottle of 250 cc. capacity, dissolve it in 10 cc. of chloroform, add 25 cc. of iodobromide T.S., accurately measured from a burette or pipette, stopper the bottle securely, and allow the mixture to stand for half an hour[2] in a cool place protected from light. After this time it must still retain a brown color; if the color is not brown a new test should be started, using a smaller quantity of the fat or oil. Then add in the order named 30 cc. of potassium iodide T.S., 100 cc. of distilled water, and tenth-normal sodium thiosulphate in small, successive portions, shaking thoroughly after each addition, until the color of the mixture becomes quite pale. Now add a few drops of starch T.S. and continue the addition of tenth-normal sodium thiosulphate until the blue color is discharged. While this test is being carried out, make a blank test by mixing exactly the same quantities of reagents and titrate the free iodine with tenth-normal sodium thiosulphate as directed above. The difference in the number of cc. of tenth-normal sodium thiosulphate consumed by the blank test and the actual test, multiplied by 1.269 and divided by the weight of the fat or oil taken, gives the iodine value.

Melting Points

(U. S.)

For the purpose of the Pharmacopœia the melting point is defined as that interval of temperature within which the substance is observed to melt when treated as directed below.

For the determination of the melting point, Pharmacopœial substances are divided into two classes:

Class I.—Substances readily reduced to a powder; *Class II.*—Substances not readily reduced to a powder, such as fats, fat acids, paraffin, petrolatum, and waxes.

Apparatus required (see illustration):

1. *A round-bottom, glass tube* of from 30 mm. to 40 mm. internal diameter and about 10 cm. long, flaring slightly at the top like an ordinary test tube. The walls of the tube are not more than 1.5 mm. thick at any point. The tube is made of glass which will permit heating over an open Bunsen flame.
2. *A stirring device,* which can be made from a glass rod of about 2 mm. external diameter. It is made circular at the end to fit the container (1) and is bent twice at right angles above the top of the container to bring its outer end within reach for convenient manipulation.
3. *A standard thermometer* covering the desired range of temperature (page 1549).
4. *An auxiliary thermometer* (page 1550).
5. *A capillary glass tube* about 6 cm. long and from 0.8 to 1.2 mm. internal diameter, the walls from 0.2 to 0.3 mm. thick and the tube closed at one end.

Procedure for Class I:

Reduce the substance to a very fine powder and, unless otherwise stated, render it anhydrous, when it contains water of crystallization, by drying it at the temperature given in the text, or, when the substance contains no water of crystallization, by drying it for twenty-four hours over sulphuric acid.

Select a bath suitable for the melting temperature to be determined, and fill the container to a depth which will permit of such immersion of the thermometer that the upper end of the bulb will be from 2 to 3 cm. below the surface of the bath and the lower end of the bulb about equally distant from the bottom of the container.

Charge the capillary glass tube with sufficient of the dry powder to form a column in the bottom of the tube from 2.5 to 3.5 mm. high when packed down as closely as possible by moderate tapping on a solid surface. Attach the capillary tube to the thermometer by wetting both with the liquid of the bath or by means of a piece of platinum wire and adjust it so that the substance is centrally located by the side of the thermometer bulb. Heat the bath by means of a free Bunsen flame until a temperature 25° C. below the supposed melting point is reached, then carefully regulate the rate of rise in temperature to about 3° per minute until the substance begins to melt (the temperature at which the column of the substance is observed to collapse definitely against the sides of the tube at any point is defined as the beginning of melting), and from that time carefully regulate the rise in temperature to about 0.5° per minute until the melting is complete. (The temperature at which the substance becomes liquid throughout is defined as the end of melting). The bath must be stirred constantly throughout the heating.

The result thus obtained as the melting interval must be adjusted by applying the calibration correction and that for the emergent stem, as follows:

Attach the auxiliary thermometer, as shown in the illustration, so that the center of its bulb is as close as possible to the stem of the main thermometer at a point midway between the surface of the bath and the supposed melting point. In order to prevent the heat from the burner or currents of cold air from affecting the temperature of the auxiliary thermometer, it is advisable to adjust to the stem of the main thermometer a movable platform made of stiff paper, having its edges folded so as to form a box-like shield surrounding the bulb of the auxiliary thermometer. Note the temperature registered by the auxiliary thermometer at the end of the melting of the substance and calculate the emergent stem correction by the following formula:

$$\text{correction} = 0.00015 \times N\ (T - t)$$

in which N represents the number of degrees of emergent stem from the bath, T the temperature at the end of melting, and t the temperature registered by the auxiliary thermometer; the correction to be added to the observed reading of the main thermometer.

To avoid the necessity of determining the emergent stem correction each time a melting point is taken, the corrections for intervals of 10° C. may be determined (at about 25° C. room temperature) and the results plotted on cross-section paper, the temperature of the bath represented by the abscissæ and the amount of correction by the ordinates. The correction for any intermediate temperature can then be interpolated.

---

[1] 0.15 to 0.18 Gm. for linseed oil, 0.18 to 0.2 Gm. for cod liver oil, and 0.8 to 1.0 Gm. for oil of theobroma.

[2] One hour is required for castor oil and linseed oil.

NOTE: Suggestions regarding liquids to be used for baths in Class I:

For temperatures up to 200° C., a purified, concentrated sulphuric acid is a suitable bath. For higher temperatures, up to about 350° C., a pure grade of cotton-seed oil (almost colorless) will serve for a limited number of determinations. Other, though less desirable, substitutes for sulphuric acid at high temperatures are: (1) a pure grade of paraffin which has been freshly distilled; (2) clean, white, artificial (cotton seed) lard. A very satisfactory bath is prepared by cautiously boiling together, for five to ten minutes under a hood, a mixture of 70 parts of sulphuric acid and 30 parts of potassium sulphate, stirring constantly until the potassium sulphate is completely dissolved.

Procedure for Class II:

Carefully melt the substance to be tested at as low a temperature as possible and draw it into a capillary tube, which is open at both ends, to a depth of about 10 mm. Cool the charged tube at 10° C., or lower, for twenty-four hours, or in contact with ice for at least two hours. Then attach the tube to a standard thermometer by means of a rubber band, adjust and heat it in a water bath, as directed in Class I, except that, within 5° of the assumed melting temperature, the rate of rise of temperature is carefully regulated to about 0.5° per minute.

The temperature at which the substance is observed to rise in the capillary tube is taken as the melting point.

Optical Rotation

(U. S.)

In a ray of ordinary light the transverse vibrations take place indifferently in any plane about the line of propagation. When these waves are limited to a single plane, they are termed polarized and the phenomenon is known as polarization.

Many organic substances, either liquid or in solution in suitable solvents, when examined in a specially constructed optical apparatus called a polariscope, are capable of rotating the plane of polarization of a ray of light either to the right or to the left. Such substances are termed "optically active," and when rotating to the right are designated as "dextrorotatory" and when rotating to the left, as "lævorotatory." Substances which do not possess this property of optical rotation are termed "optically inactive." Optical activity in many instances is intimately connected with the chemical constitution of a substance, frequently becoming a specific property, and its determination is of considerable value.

Among the substances recognized in the Pharmacopœia, there are a number, particularly certain essential or volatile oils and related bodies, for which the determination of the angle of rotation of a ray of polarized light, or, in some cases, the proof of their optical inactivity, affords the most simple and positive evidence of their identity or purity.

The instruments used for polariscopic tests, vary in their construction and are classified as polarimeters (measuring angular rotation) and saccharimeters (measuring percentage of sucrose). Those which are most generally adapted for the examination of the substances mentioned above are the penumbral or so-called "half-shadow" instruments of Laurent and of Schmidt and Hansch in which the two sides of the field of vision are capable of becoming unequally illuminated. Polarimeters permit the angle of rotation to be read off in degrees or fractions of a degree of a circle. Saccharimeters, set to measure percentage of sucrose, give readings in terms of divisions of the sugar scale.

These determinations are best made in a dark room, and by means of monochromatic light, the latter being obtained by introducing into a non-luminous flame, on a loop of platinum wire, a small bead of fused sodium chloride. The light thus radiated corresponds with the line D of the solar spectrum.

The following factors are employed for converting readings of a saccharimeter into readings of a polarimeter: 1 division Laurent sugar scale equals 0.2167° angular rotation D.; 1 division Schmidt and Hansch sugar scale equals 0.346° angular rotation D.

Since the deviation of the plane of polarization either to the right or to the left of the zero point is directly proportional to the length of the column of liquid, it is essential that the observations should be made with tubes of a definite length, such as 200, 100, 50, or 25 mm. The selection of the length of the tube to be employed is, however, usually dependent upon the depth of color of the liquid and the magnitude of its optical rotation.

The rotatory power of an optically active, liquid substance, observed with sodium light, and referred to the ideal density 1, and in a tube having a length of 1 decimeter (100 mm.), is designated as its *specific rotatory power*. This is usually expressed by the term $[a]_D$. Since, however, not only the density of an optically active liquid, but also its rotation, is influenced by the temperature, the specific rotation varies with the latter. In stating the specific rotation it is, therefore, necessary to indicate at what temperature the rotation and the density of the liquid have been determined. But for the same temperature the specific rotation of a pure, optically active liquid is always a constant number. The temperature used in the text of the Pharmacopœia is 25° C., except when otherwise indicated. For saccharimeters the temperature is fixed at 20° C. by international agreement.

For calculating the specific rotatory power of an optically active liquid substance, or solution of an optically active solid, the following formulas are of general application:

I. For liquid substances $$[a]_D = \frac{100 \times a}{L \times d}$$

II. For solutions of solids $$\left\{ \begin{array}{l} [a]_D = \dfrac{10000 \times a}{L \times p \times d} \\[2ex] \text{or} \quad [a]_D = \dfrac{10000 \times a}{L \times c} \end{array} \right.$$

For calculating these formulas, the determination of the following factors is necessary:

a = the angle of rotation of the liquid or solid observed with sodium light.
L = the length of the tube in millimeters.
d = the density of the active liquid or solution.
p = the amount of active substance in 100 parts by weight of the solution.
c = the number of grammes of active substance in 100 cc. of solution.

Proximate Assays

(U. S)

General Directions for Alkaloidal Assays

Fineness of Powders.—The portion to be assayed, which must represent the entire drug, is to be in powder of specified fineness. This is interpreted to mean that the drug powder must not be coarser than the size specified, but finer powders may be used.

Extraction of the Alkaloids. **Extraction with Immiscible Solvents.**—For the extraction of alkaloids from an ethereal or chloroformic solution, use dilute acid. The strength of the acid and the quantity employed are left to the discretion of the operator, but it is advisable to use as small quantities as can be conveniently handled. Shaking should not be violent, but should be sufficient to mix the liquids thoroughly without forming an emulsion. The extraction with acid must be repeated until the alkaloid is completely removed from the ethereal or chloroformic liquids. Each portion of acid solution as drawn off should be filtered through cotton or filter paper. If preferred, the combined acid solutions may be washed with a little chloroform or ether, this in turn washed with distilled water and the water added to the acid solution.

In shaking out an alkaline aqueous solution with an immiscible solvent, the process must be repeated until the extraction of the alkaloid is complete. Each portion of solvent as drawn off should be filtered through cotton or filter paper.

Care must be taken to avoid loss of alkaloidal solutions through imperfect separation, creeping, or other similar conditions.

Ether-Chloroform Mixture.—When a mixture of ether and chloroform is employed, the proportion of the mixture is to be three volumes of ether and one volume of chloroform, cooled to working temperature after being mixed.

Evaporation of Solvents.—The evaporation of the final alkaloidal solution may be conducted by distillation, by evaporation on a water bath, or by means of a current of warm air. In evaporating chloroform solutions, the residue should be treated with ether or alcohol which is in turn evaporated to carry off the last traces of chloroform.

As the alkaloids from hyoscyamus are very sensitive to heat, a solution of these alkaloids should not be evaporated to dryness on a water bath. After the last trace of chloroform has evaporated spontaneously, 1 or 2 cc. of neutral alcohol should be added and warmed but not entirely evaporated, then cooled and titrated immediately.

Titration of the Alkaloids.—When the alkaloid is to be estimated by titration, the residue is dissolved in neutralized alcohol, the volumetric acid, accurately measured, is added, and followed by a convenient quantity of distilled water. The excess of acid is immediately determined by titration with fiftieth-normal sodium hydroxide. If preferred, the residue is dissolved in ether or chloroform, the volumetric acid and distilled water added, and the ether or chloroform expelled by gentle heat before titrating.

Indicators.—The indicators to be employed in the titration of alkaloids are cochineal T.S. and methyl red T.S. These are interchangeable and either may be used at the discretion of the operator.

Gravimetric Determination.—When the alkaloid is to be estimated gravimetrically, the solvent is evaporated, as above directed, in a tared flask or beaker. The residue is dried to constant weight at 100° C. and weighed.

Type Processes for Alkaloidal Assays

(U. S.)

Type Process A for Drugs—Aliquot Part Method. **Extraction of the Drug.**—Place the accurately weighed drug in a dry flask or bottle of suitable capacity, add the required volume of solvent, accurately measured, stopper securely with a well-fitting cork stopper, and shake. Allow to stand for at least five minutes, add 10 cc. of ammonia T.S., stopper tightly, and shake for one hour in a mechanical shaker, or intermittently during two hours. In case of intermittent shaking agitation must be vigorous for at least one minute and be repeated at intervals of not more than fifteen minutes. Allow the mixture to stand over night, again shake intermittently during one-half hour, and then allow the drug to settle. If the supernatant liquid is not clear, add a few cc. of distilled water, shake vigorously, and again allow to settle.

Decant an aliquot part of the liquid, accurately measured at approximately the same temperature at which the original solvent was measured. Transfer the liquid to a separator, rinsing the measuring container with a small quantity of the solvent and adding the rinsing to the separator.

Shaking out with Acid.—Completely extract the alkaloid from the ethereal or chloroformic solution by shaking with successive portions of dilute sulphuric acid, and filtering each portion drawn off or washing with ether or chloroform if preferred. After extracting with several portions of acid, test a few drops of the last portion used for the presence of alkaloid. Extraction must be continued until not more than a very faint cloudiness results upon the addition of a drop of mercuric potassium iodide T.S. or, in the case of hydrastis or colchicum, upon the addition of a drop of iodine T.S.

Shaking out with Immiscible Solvent.—Add a portion of the specified solvent to the combined acid solutions and make the mixture alkaline with ammonia T.S. Completely extract the alkaloid from the aqueous liquid with successive portions of the solvent, filtering each portion as drawn off. After extracting with several portions of the solvent, evaporate about 1 cc. of the last portion used, dissolve the residue in a few drops of dilute acid, and test for the presence of alkaloid. Extraction must be continued until not more than a very faint cloudiness results upon the addition of a drop of mercuric potassium iodide T.S. or, in the case of hydrastis or colchicum, upon the addition of a drop of iodine T.S.

Determination of Alkaloidal Content.—Determine the alkaloid volumetrically or gravimetrically as directed.

TYPE PROCESS B FOR DRUGS—TOTAL EXTRACTION METHOD. **Extraction of the Drug.**—Place an accurately weighed quantity of the ground drug in a small cylindrical percolator (see illustration), previously prepared by packing the outlet with cotton. Add a sufficient amount of the solvent to saturate the drug completely and mix thoroughly. Cover the percolator and allow it to stand at least five minutes, then add 5 cc. of ammonia T.S., and mix this thoroughly with the drug. After macerating for one hour, pack the drug firmly, place a pledget of cotton above it and percolate slowly with the solvent until the drug is completely extracted. The percolation must be continued until, upon evaporating 3 or 4 cc. of the percolate,dissolving the residue in a few drops of dilute acid, and adding a drop of mercuric potassium iodide T.S., only a very faint cloudiness results.

Any suitable percolator may be used, but one similar in form and size to that illustrated is recommended.

From this point proceed as directed under *Type Process A*, beginning with the words "Transfer the liquid to a separator."

TYPE PROCESS C FOR GALENICAL PREPARATIONS—ALIQUOT PART METHOD.—**Preparation of the Sample.** *Powdered Extracts.*—When powdered extracts are assayed by the aliquot part method, they are to be treated as directed under the powdered drug. If the extract has a tendency to form lumps in the solvent, mix it with an equal bulk of clean sand or powdered pumice. If lumps form after the addition of the ammonia, they should be disintegrated by the addition of a little water.

Pilular Extracts.—Liquefy an amount of extract, accurately weighed, approximating the quantity directed, by warming with sufficient diluted alcohol, or with the menstruum used in making the extract, stirring with a glass rod. To the thoroughly liquefied extract, contained in a small evaporating dish, add sufficient sawdust or other suitable material (see below) to absorb the liquid, and dry at a temperature not exceeding 60° C. Transfer the dry mixture to a flask or bottle containing the specified quantity of solvent and remove any traces of material adhering to the dish by rinsing with successive small portions of ammonia T.S., using a total of 10 cc. and adding the ammoniacal rinsings to the solvent. Continue as directed under Type Process A, beginning with the words "stopper tightly and shake for one hour."

Fluidextracts.—Pipette fluidextracts directly upon the sawdust, or other suitable material (see below), contained in a small evaporating dish, dry at a temperature not exceeding 60° C., and transfer as directed under *Pilular Extracts* to a flask or bottle containing the specified quantity of solvent. Proceed as directed under Type Process A, beginning with the words "stopper tightly and shake for one hour."

Tinctures.—Concentrate the specified quantity of tincture, by evaporation at a temperature not exceeding 60° C., to a volume of about 10 to 15 cc., add sufficient sawdust or other suitable material (see below) to absorb the liquid, and continue the heat until dry. Transfer the dry mixture, as directed under *Pilular Extracts,* to a flask or bottle containing the specified quantity of solvent. Then proceed as directed under Type Process A, beginning with the words "stopper tightly and shake for one hour."

Absorbents.—The absorbents employed may be sawdust, gauze, cheesecloth, paper pulp, asbestos fiber, absorbent cotton or any similar suitable substance. Sawdust should be clean, not resinous, and must not show the presence of alkaloids when tested as follows: Macerate 5 Gm. in 50 cc. of ether-chloroform mixture and 10 cc. of ammonia T.S., shaking frequently during two hours. Decant 10 cc. of the clear ethereal liquid, evaporate to dryness, and treat the residue with 1 cc. of diluted sulphuric acid. Test portions of the acid liquid for alkaloids with mercuric potassium iodide T.S. and with iodine T.S. If necessary, sawdust may be purified for use in assays by extracting it in a percolator, first with a 1 per cent. solution of sodium hydroxide, then with a 1 per cent. solution of hydrochloric acid, finally washing with distilled water until free from acid and soluble salts, and drying. The last portions of the acid percolate must give no test for alkaloid with mercuric potassium iodide T.S. or with iodine T.S.

TYPE PROCESS D FOR GALENICAL PREPARATIONS—TOTAL EXTRACTION METHOD. **Preparation of the Sample.** *Powdered and Pilular Extracts.*—Liquefy an amount of extract, accurately weighed, approximating the quantity directed, by digesting in about 10 cc. of diluted alcohol, or in the menstruum used in making the extract. Transfer the liquid to a separator containing a portion of the specified solvent, and rinse all traces of the extract from the dish, using small portions of diluted alcohol, or menstruum, and adding the rinsings to the separator. Dilute the alcoholic liquid with an equal quantity of distilled water, add sufficient ammonia T.S. to make it decidedly alkaline, and completely extract the alkaloids by shaking with successive portions of the solvent. Complete the assay as directed under Type Process A, beginning with the words "shaking out with acid."

Fluidextracts.—Pipette fluidextracts directly into a separator containing a portion of the specified solvent, add a volume of distilled water about equal to that of the fluidextract taken, render the liquid alkaline by the addition of ammonia T.S., and completely extract the alkaloids by shaking out with successive portions of the solvent. Complete the assay as directed under Type Process A, beginning with the words "shaking out with acid."

Tinctures.—Concentrate the specified quantity of tincture, by evaporation at a temperature not exceeding 60° C., to a volume of about 10 to 20 cc. Transfer the concentrated liquid to a separator containing a portion of the specified solvent, and rinse all traces of the liquid from the dish, using small portions of diluted alcohol, and adding the rinsings to the separator. Add a volume of distilled water equal to that of the alcoholic liquid, render the liquid alkaline by the addition of ammonia T.S., and completely extract the alkaloids by shaking out with successive portions of the solvent. Complete the assay as directed under Type Process A, beginning with the words "shaking out with acid."

Refractive Index

(U. S.)

When a ray of light passes from one transparent substance into another of different density, it is deflected, except when it enters perpendicularly to the surface of contact. The direction of the deviation is dependent upon the difference of density of the two substances; the extent is also influenced by this difference.

This deviation is termed "refraction." When the ray passes from a substance of given density to one of greater density (*e.g.*, from air into glass) the refraction is towards the perpendicular meeting the surface at the point of contact; when passing from a substance of greater density to one of less (*e.g.*, from water into air) the ray deviates from the perpendicular at the point of contact.

Quantitative measurements of refraction are expressed as "indices of refraction," the index being the figure obtained by dividing the sine of the angle that the incident ray makes with the perpendicular, by the sine of the angle that the refracted ray makes with the same perpendicular; that is, it is the ratio between these sines. Thus, the ratio for a ray of light passing from air into water at standard temperature is about 4:3 or, expressing it decimally and with greater exactness, 1.336. This is, therefore, the index of refraction of water. The determination of the refractive index is accomplished by means of optical instruments known generally as *refractometers*, which are of several types. Some of these give figures on an arbitrary scale, the actual refractive index being ascertained by consulting a table.

As the exact temperature at which the examination is made is of great importance, all of the instruments are provided with attachments for circulating water of the proper temperature about the prisms or about the vessel containing the liquid to be observed, and are also equipped with thermometers for observing the temperature very closely.

The principal instruments in use are as follows:

Pulfrich refractometer.—This instrument is used chiefly for purely scientific investigations. It is adapted for use with liquids and solids of all degrees of refractive power. When a liquid is to be examined, it is placed in a small cylindrical glass vessel immediately above the observation prism. When solids are to be examined, the glass cylinder is removed and the solid (previously polished) is placed in direct contact with the observation prism. The reading of this instrument is made by noting a boundary line between a light and a dark field in its position with reference to a graduated scale upon which the refractive index is directly expressed.

The Abbe refractometer.—This is an instrument of wide utility, designed primarily for the examination of liquids. Only a few drops of the liquid are required for an observation. This is spread in a thin film between the two observation prisms. The index of refraction is also read off directly upon the scale of this instrument, in which, as in the Pulfrich refractometer, a boundary line between a light and a dark field is the observation line.

The Zeiss butyro-refractometer.—This instrument is especially designed for the examination of fixed oils and fats. It is not applicable to aqueous or alcoholic liquids. The distinctive line for observation in this instrument is the border line of total reflection which is a narrow line capable usually of being accurately read to within a tenth of a unit of the arbitrary scale used. Sometimes this observation line is accompanied by a blue and a red fringe or haze which interferes with the accuracy of the reading. Should a close reading be mpossible on this account it will be found necessary to use the monochromatic sodium flame for the observation (see under *Optical Rotation*).

Zeiss immersion refractometer.—This is adapted for the examination of aqueous, oily, or alcoholic liquids. The distinctive line for observation is as described under the preceding instrument, the border line of total reflection in this case being much sharper and capable of being more accurately read.

For making observations of the entire range of pharmacopœial substances, the Abbe instrument is the one generally selected, the Pulfrich instrument not being in common use, and the Zeiss butyro- and immersion refractometers not covering the entire range necessary.

Rosin Test

(U. S.)

For testing for rosin as an adulterant in resins, gum resins and balsams, place in a small mortar 1 Gm. of the substance, powdered or crushed if necessary, and add 10 cc. of purified petroleum benzin unless the substance contains free cinnamic or benzoic acid, in which case the petroleum benzin should be replaced by xylene. Triturate well for one or two minutes, filter into a test tube, and add to the filtrate 10 cc. of a fresh aqueous solution of copper acetate (1 in 200). Shake well and allow the liquids to separate: the benzin or xylene layer should not show a green color (*rosin*).

Saponification Value

(U. S.)

The saponification value is the number of milligrammes of potassium hydroxide required to neutralize the free fatty acids and saponify the esters of 1 Gm. of a fat, oil, wax, etc. It is determined as follows: Place from 1.5 to 2 Gm. of the filtered fat or oil, accurately weighed, in a flask of from 200 to 250 cc. capacity, and add to it exactly 25 cc. of alcoholic half-normal potassium hydroxide (page 1571). Insert into the neck of the flask, by means of a perforated stopper, a glass tube from 70 to 80 cm. in length and from 5 to 8 mm. in diameter, and heat the flask on a water bath for half an hour, frequently rotating the contents. Then add 1 cc. of phenolphthalein T.S. and titrate the excess of potassium hydroxide with half-normal hydrochloric acid. Make a blank test at the same time, using exactly the same amount of alcoholic half-normal potassium hydroxide. The difference in the number of cc. of half-normal hydrochloric acid consumed in the actual test and in the blank, multiplied by 28.06 and divided by the weight of the fat or oil taken, gives the saponification value.

Solubilities

The statements concerning solubilities quoted in this Pharmacopœia are not intended as physical constants in the strict sense of this term, but primarily as information required by physicians and pharmacists in connection with the preparation and dispensing of medicines.

The solubility of Pharmacopœial compounds in given solvents is considered to be of minor importance as a means for their identification or determination of purity, as the other tests contained in the description of each article in the text cover both identity and purity.

The following points must be observed in the accurate determination of solubilities: 1. Purity of both the dissolved substance and the solvent is essential since impurities in either affect the solubility to a greater or less extent. 2. Constancy of temperature must be accurately maintained during the course of the determination. 3. Complete saturation must be secured. 4. Accurate analysis of the saturated solution and correct expression of the results are imperative. In connection with the above named essential features of a correct solubility determination, attention must be given to the varying rates of solution of different compounds, and to the marked effect of the degree of fineness of the particles upon the time required for the saturation of the solution. In general, it may be said that an equipment comprising a thermo-regulator and a constant agitation device is indispensable for accurate solubility determinations.

The solubility data given throughout this volume have for the most part been determined under the above described conditions, and will, therefore, frequently show a somewhat greater solubility than would be found in the daily experience of most pharmacists.

When in Pharmacopœial texts it has not been possible, or in some instances not desirable, to indicate exact solubility, a descriptive term has been used. The following table indicates the meaning of such terms:

	Solvent
"Very soluble"	Less than 1 part.
"Freely soluble"	From 1 to 10 parts.
"Soluble"	From 10 to 30 parts.
"Sparingly soluble"	From 30 to 100 parts.
"Slightly soluble"	From 100 to 1000 parts.
"Very slightly soluble"	From 1000 to 10,000 parts.
"Practically insoluble"	More than 10,000 parts.

Method for Determining Solubilities.—In brief, this consists in preparing a saturated solution of the given substance and ascertaining, by analysis, the amount present in a definite quantity of the solution. Complete saturation can be attained most readily by constant stirring or agitation by means of a suitable mechanical contrivance. A simple apparatus for this purpose consists of a test tube of medium size fastened upright in a water bath maintained at constant temperature. The solvent and excess of solids are placed in the tube and stirred by means of a motor-driven rotating glass spiral. After a given period of stirring, a definite weight of the clear solution is analyzed and the stirring continued for an additional period of several hours. If analysis shows no increase of dissolved substance after the second period of stirring, the result is to be taken as the solubility at the particular temperature. Minute details of methods for determining solubilities are described in Bulletin No. 67 of the Hygienic Laboratory, U. S. Public Health Service.

Sterilization

(U. S.)

The term "sterilization" as employed in the practice of medicine and pharmacy means the destruction or removal of bacteria or their spores and other living organisms. This may be accomplished in various ways, depending upon the nature of the material to be sterilized.

A sterile condition can be maintained only so long as the substance or material is kept from contact with air or other media which may carry micro-organisms.

The important subject of sterilization cannot be treated exhaustively, nor can the details of scientific technique be fully described in this chapter.

Two of the chief reasons for failure in attempted sterilization are (*a*) lack of penetration of the maximum degree of heat to all parts of the substances to be sterilized, due to insufficient time, too close packing, or a source of heat not sufficiently powerful to secure and maintain the desired temperature throughout the entire contents of the sterilizer, and (*b*) in the case of moist sterilization, incomplete saturation of the materials and surfaces to be sterilized. Temperatures necessary for dry sterilization are much higher than those needed for moist sterilization, so that if the steam is superheated or mixed with dry air, the sterilization may be insufficient.

Suggested methods for the sterilization of different classes of material are as follows:

Glass and Metal Utensils.—These may be sterilized by heating at a temperature of 170° C. maintained for two hours in a hot-air sterilizing oven, or in a closed vessel (autoclave) under steam pressure at a temperature of 115° C. maintained for thirty minutes. In steam sterilization, thorough saturation may be provided by arranging the utensils in the sterilizer with unstoppered openings down so that there will be no dead horizontal air spaces, or by the use of a preliminary vacuum to allow the steam to displace the air in all parts, or by insuring that all utensils contain at least one-eighth of one per cent. of their volume of water when placed in the autoclave. As the presence of even a minute quantity of alkali is objectionable in glass containers in certain cases, the process of sterilization should in such instances be preceded by a thorough cleansing of the bottle, ampule, or other receptacle with 1 per cent. hydrochloric acid, followed by a thorough rinsing with distilled water. Relatively insoluble glass should be used and sterilization should be by dry heat rather than by steam.

Cork stoppers should not be used for containers to be sterilized. Cotton stoppers may be employed, and when used may be wrapped in a layer of gauze and covered with stout paper or tinfoil as described under *Aqua Destillata Sterilisata.* Rubber stoppers should be wrapped and should be sterilized separately or attached to the outside of the necks of the containers. These stoppers should be long enough so that they may be inserted and removed without touching the lip of the container with the fingers. The sterilized wrapper of the stopper may be used as a cap. Glass-stoppered containers are sterilized preferably by dry heat, capped, and the stopper separated from tight contact with the neck of the container by a strip of paper.

The flame from a Bunsen burner applied directly to a surface for ten seconds may be used for sterilizing surfaces which are not adversely affected by such application.

Heating in a current of steam for thirty minutes, or boiling for five minutes in water, or in an aqueous 0.1 per cent. solution of sodium bicarbonate (to prevent rusting), will kill all non-spore-bearing organisms and some spore-bearing organisms.

Articles Made of Rubber.—Rubber tubing and rubber stoppers should not be sterilized by hot air, but by steam under pressure, with the precautions indicated above, or by boiling for thirty minutes in a 2 per cent. aqueous solution of cresol or phenol.

Medicinal Substances Not Easily Decomposed by Heat.—If in aqueous solution, these substances should be sterilized by steam under pressure, as described under *Glass and Metal Utensils.* In order that the exposure to heat may be the shortest which will effect thorough sterilization, the container should not be of thick glass and should be of as small a capacity as can conveniently be used. The preliminary heating before the temperature of 115° C. is reached may be shortened by admitting the steam to the autoclave under pressure from a separate generating plant, delivering a pressure constantly above eighteen pounds. The stoppers should be of cotton, as above described, and a wrapped rubber stopper should be attached to each container unless the contents are for immediate use.

If the substances are dry or oily, they should be sterilized by dry heat, preferably in glass-stoppered containers, as described under *Glass and Metal Utensils.* Cap the utensil or container with parchment paper before sterilization for protection against contamination and do not remove the paper until the substance is to be used.

Medicinal Substances Which Are Decomposed by Heat Above 100° *C. and in Which Bacteria May Multiply.*—These substances may be rendered approximately sterile by *fractional sterilization* on three successive days at 100° C. in boiling water or in streaming steam. If boiling water is used, the substances should be contained in glass-sealed ampules and be kept entirely immersed in the water by means of a metal screen or other weight; the water is then boiled at 100° C. for fifteen minutes and this is repeated on each of the three days. After completion of the sterilization, the ampules are tested for permeability and any showing permeability to liquid are discarded. If streaming steam is used, the substances should be in containers of thin, heat-resistant glass of not over 100 cc. capacity each, stoppered with cotton as above described, and the heating chamber should be double-walled; steam is admitted continuously to the heating chamber in sufficient volume to maintain a temperature of 100° C. for thirty minutes, as indicated by a thermometer with the bulb placed close to the containers, and this is repeated on each of the three successive days. In both methods of fractional sterilization, by boiling water and by streaming steam, the containers should be kept at 35° to 40° C. during the two days between the successive heatings.

Medicinal Substances Readily Decomposed or Damaged by Heat.—Substances of solutions which are decomposed when subjected to heat as directed in the preceding section (this includes solutions of many alkaloids) may be prepared in an approximately sterile condition as directed below:

METHOD I.—Filter the liquid through a sterilized stone or porcelain filter (which has previously been tested to prove its efficiency in removing bacteria) into a sterile container protected by a sterile cover. Sterile rubber or glass tubing may be used to connect the filter with the container.

METHOD II.—Sterilize all utensils which will come in contact with the substance, such as scale-pans, or paper, spatulas, funnels, etc., either by steam, followed by drying, or by hot air, or by the Bunsen flame. After weighing out the required amount of substance, dissolve it in the required amount of sterile distilled water in a sterile, glass-stoppered container. Should the solution require filtration, use a sterilized funnel and filter paper and collect the filtrate in a sterilized container, closing it with a sterilized rubber stopper. The filtration must be conducted under a cover and in such a manner that no contamination will result.

Emulsions in Glycerin or Oil.—Approximately sterile solutions or emulsions in glycerin or oil may be prepared in the following manner: Heat glycerin or oil in flasks of thin glass containing not over 50 cc. each, for two hours at from 120° to 130° C. in a dry air sterilizer, then introduce the sterile or approximately sterile medicinal substances after the liquid has cooled. The desired medicament may be incorporated by triturating it with a sterilized pestle and mortar containing the previously sterilized medium (glycerin or oil) and the solution or emulsion should then be quickly transferred to a sterilized glass container.

Surgical Dressings.—Cotton, gauze, and ligatures (except catgut and other absorbable material) may be rendered sterile by steam under pressure or by hot air under the conditions and precautions previously indicated. It should be remembered that all surgical materials are not amenable to such thorough treatment without more or less deterioration taking place. Surgical dressings must be wrapped and packed in such a manner as to permit the penetration of steam or dry heat and at the same time so as to prevent all subsequent contamination with bacteria when removed from the sterilizer. The wrappers should be so folded that the packages may be unwrapped at the time of use without touching the contents.

Thermometers

(U. S.)

General Requirements.—The bulbs are to be of normal Corning thermometer glass, or of Jena 16III normal glass. The stems may be made of other white enamel back glass tubing having a circular cross section; the diameter of the capillary must not be greater than 0.1 mm. The diameter of the stem is to be 5.5 mm. (to within ∓ 0.3 mm.), and the maximum diameter of the bulb must not be greater than the diameter of the stem. The thermometers are to have a pear-shaped reservoir at the upper end of the capillary having a volume at least equal to the volume of the entire graduated portion of the stem. The upper end of the stem is to have a small glass ring.

Graduation.—The thermometers are all to be graduated in 0.5° (one-half degree) intervals. The 1° graduation marks are to be longer than those for the half degrees, the longer graduations preferably extending equally to the right and left of the shorter marks. The graduation marks are to be clean cut and fine, and to be uniformly well-filled with insoluble colored pigment.

Numbering.—The 100° graduations (the 0°, 100°, 200°, 300° graduations on the different thermometers) are to be numbered in full and the intermediate 5° and 10° graduations are to be numbered 5, 10, 15, etc. ..... 95, 100, 5, 10, 15, ... 95, 200, 5, 10, etc. The numbers must be distinct and easily legible, preferably in such position that they will be upright when the thermometer is vertical. The figures should not be unduly large. It is suggested that the figures opposite the 0°, 100°, 200°, 300° graduations be made about 2 mm. in height and the intermediate numbers 5, 10, 15, etc., somewhat less (about 1.4 mm.).

Annealing.—The thermometers should be so thoroughly annealed that there will be no appreciable change in their indications after long continued exposure to the highest temperature on the scale.

Error of Scale.—The maximum error at any temperature below 100° C. must not exceed 0.5°, nor exceed 1.0° in the interval 100° to 300° C.

Standardization.—The thermometers should be submitted to the Bureau of Standards for standardization, or carefully compared with thermometers actually standardized by the Bureau of Standards.

Filling Under Pressure.—Thermometers reading over 200° C. must be filled under sufficient pressure to prevent the mercury column from boiling or breaking up into small pieces.

Thermometer No. 1.—The thermometer is to be graduated from –10° to 150° C. in half degrees, the length of a 1° interval being 1.5 to 2 mm.

Thermometer No. 2.—The thermometer is to be graduated from 95° or 98° to 300° C. in half degrees, the length of a 1° interval being 1.5 to 2 mm. The length of the thermometer between the lower graduation and the lower end of the bulb should not exceed 50 mm.

Auxiliary Thermometer.—This thermometer is for emergent stem corrections. Use a standard thermometer from 15 to 20 cm. in length and graduated from 20° to 100° C., in degrees.

Thermometers for Boiling Points.—In order to avoid the necessity for an emergent stem correction, it is advisable that an accurately standardized thermometer for the Anschütz type be used for boiling points. If such a thermometer is not available, a thermometer such as is specified above (see Nos. 1 and 2) may be employed, applying the emergent stem correction as described under *Melting Points*, the length of emergent stem being measured, in degrees, from the lower end of the stopper to the highest point of the boiling temperature.

Turbidimetric Tests

(U. S.)

These tests are applied to certain official chemicals, to insure the absence of excessive amounts of chloride or sulphate.

In carrying out these turbidimetric tests, the following points are to be observed: The same quantities of the same reagents must be used in the test of the substance under examination and in the control test. The glass cylinders in which the tests are made must be of the same diameter and match in all other respects as closely as possible. The precipitating reagent must be added to both in immediate sequence.

Chloride.—The prescribed quantity of the substance to be tested is dissolved in from 30 to 40 cc. of distilled water, and the solution neutralized, if necessary, with nitric acid, using litmus paper as indicator. One cc. of nitric acid and 1 cc. of silver nitrate T.S. are added and then sufficient distilled water to make 50 cc. After mixing well and allowing to stand five minutes protected from direct sunlight, the turbidity, if any, is compared with that produced in a control test made with the specified volume of fiftieth-normal hydrochloric acid.

Bismuth Salts are first dissolved in a few cc. of distilled water and 2 cc. of nitric acid, then diluted with distilled water to 50 cc.

Sulphate.—The specified quantity of the substance to be tested is dissolved in from 30 to 40 cc. of distilled water, and the solution neutralized if necessary, with hydrochloric acid, using litmus paper as indicator. One cc. of diluted hydrochloric acid and 1 cc. of barium chloride T.S. are added and then sufficient distilled water to make 50 cc. After mixing well, it is allowed to stand for ten minutes and the turbidity, if any, is compared with that produced in a control test made with the specified volume of fiftieth-normal sulphuric acid.

If the solution, after the addition of acid, is not perfectly clear, it is filtered through a filter paper free from chloride or sulphate, then the silver nitrate or the barium chloride is added.

In applying the turbidimetric tests to salts of heavy metals, which normally show an acid reaction, their aqueous solutions prepared for the test are not to be neutralized.

When the tests for chloride or sulphate are to be applied to a specified volume of a solution of a substance prepared as directed in the text, and the permissible limit for these impurities corresponds to 0.2 cc. or less of fiftieth-normal hydrochloric or sulphuric acid, the solution is not to be further diluted. The control test is also made with the same volume of water (or other specified solvent) as in the test.

Unsaponifiable Matter

(U. S.)

The term "unsaponifiable matter" is understood to mean substances present in oils or fats that are not saponifiable by caustic alkali and are insoluble in water. It is determined as follows: Heat 5 Gm. of the oil or fat under a reflux condenser with a solution of about 2 Gm. of potassium hydroxide in 40 cc. of alcohol for an hour or until completely saponified. Evaporate most of the alcohol, dissolve the residue in 50 cc. of hot distilled water, and transfer the solution to a separator, rinsing the flask with 25 or 50 cc. of hot distilled water. Cool, and shake with two successive portions of 50 cc. each of ether, adding a few cc. of alcohol to facilitate the separation of the two liquids. Wash the combined ether extracts with small portions of distilled water until the water is not reddened by phenolphthalein T.S. Transfer the ether solution to a tared dish or beaker, evaporate the ether on a water bath, dry the residue at a temperature not exceeding 100° C., and weigh.

Vegetable Drugs, Sampling and Analysis

(U. S.)

SAMPLING FROM ORIGINAL CONTAINERS.—I. It is recommended that gross samples of vegetable drugs in which the component parts are 1 cm. or less in any dimension, and all powdered or ground drugs, be taken by means of a sampler which removes a core from the top to the bottom of the container, not less that two cores being taken in opposite directions; that when the total weight of the drug to be sampled is less than 100 kilos (200 pounds), at least 250 Gm. shall constitute an *official sample*; that when the total weight of the drug to be sampled is in excess of 100 kilos, repeated samples shall be taken by the above method, and according to the schedule given below, mixed and quartered, two of the diagonal quarters being rejected, the remaining two quarters being combined and carefully mixed, and again subjected to a quartering process in the same manner until two of the quarters weigh at least 250 Gm., which latter quarters shall constitute an *official sample.*

II. It is recommended that gross samples of vegetable drugs in which the component parts are over 1 cm. in any dimension be taken by hand; that when the total weight of the drug to be sampled is less than 100 kilos, at least 500 Gm. shall constitute an *official sample,* and this shall be taken from different parts of the container or containers; that when the total weight of the drug to be sampled is in excess of 100 kilos, repeated samples shall be taken by the above method and according to the schedule below, mixed and quartered, two of the diagonal quarters being rejected, and the remaining two quarters being combined and carefully mixed, and again subjected to a quartering process in the same manner until two of the quarters weigh not less than 500 Gm., which latter quarters shall constitute an *official sample.*

SCHEDULE RECOMMENDED FOR SAMPLING

Number of packages in shipment	*Number of packages to be sampled*
1 to 10	1 to 3
10 to 25	2 to 4
25 to 50	3 to 6
50 to 75	6 to 8
75 to 100	8 to 10

When over 100, the total number sampled should not be less than 10.

III. When the total weight of a drug to be sampled is less than 10 kilos it is recommended that the above methods be followed but that somewhat smaller quantities be withdrawn, and in no case should the final *official sample* weigh less than 125 Gm.

IV. In addition to the withdrawing of *official samples* according to methods I, II, and III, the *official sample* may consist of the total amount of a direct purchase made by Federal, State or Municipal Food and Drugs' Act enforcement officials.

Foreign Organic Matter in Whole Vegetable Drugs.—V. Withdraw from 25 to 500 Gm. from the *official sample,* spread out in a thin layer, and separate the foreign organic matter by hand as completely as possible. Weigh and determine the per cent. of foreign organic matter, calculated upon the weight of drug taken. The maximum quantity should be used for coarse or bulky drugs.

Preparation of Vegetable Drugs for Analysis.—VI. The following method is to be used where specific directions are not otherwise given in the text: Withdraw as much as may be necessary of the *official sample* by quartering, taking pains to see that the portion is representative of the gross sample. In the case of unground or unpowdered drugs, grind the withdrawn sample so that it will pass through a No. 20 standard-mesh sieve. If the sample cannot be ground reduce it to as fine a state as possible. Mix by rolling it on paper or sampling cloth, spread it out in a thin layer and withdraw the portion for analysis.

Total Ash in Vegetable Drugs.—VII. Accurately weigh a quantity of the ground drug, representing from 2 to 4 Gm. of the air-dried material, in a tared crucible and incinerate at a low temperature, not to exceed very dull redness, until free from carbon, and determine the weight of the ash. If a carbon-free ash cannot be obtained in this way, exhaust the charred mass with hot distilled water, collect the insoluble residue on an ashless filter paper, incinerate the residue and filter paper until the ash is white or nearly so, then add the filtrate, evaporate it to dryness and heat the whole to a low redness. If a carbon-free ash cannot be obtained in this way, cool the crucible, add 15 cc. of alcohol, break up the ash with a glass rod, burn off the alcohol, and again heat the whole to a low redness. Finally determine the weight of the ash. Calculate the percentage of total ash from the weight of the drug taken.

Acid-insoluble Ash in Vegetable Drugs.—VIII. Boil the ash obtained under paragraph VII with 25 cc. of diluted hydrochloric acid for five minutes, collect the insoluble matter in a Gooch crucible or on an ashless filter, wash with hot distilled water, ignite and weigh. Determine the per cent. of acid-insoluble ash calculated from the weight of drug taken.

Moisture in Vegetable Drugs.—IX. Preparation of Sample. In the case of unground or unpowdered drugs, prepare about 10 Gm. of the *official sample* by cutting, granulating, or shredding, so that the parts are about 3 mm. in thickness. Seeds or fruits smaller than 3 mm. should be cracked. High-speed mills should not be used for preparing the sample and care should be taken that no appreciable amount of moisture is lost during the preparation, and that the portion taken is representative of the *official sample.*

Moisture Method for Drugs Containing no Constituents Volatile at 100° C.—X. Accurately weigh about 10 Gm. of the drug as prepared under paragraph IX in a tared evaporating dish. Dry at a temperature of 100° C. for five hours, and weigh. Continue the drying and weighing at one hour intervals until the loss is not more than 0.25 per cent. in one hour's drying.

Moisture Method for Drugs Containing Ether-soluble Constituents Volatile at 100° C.—XI. Proceed as under paragraph X. Determine the volatile ether-soluble extractive (paragraph XIII) and subtract the percentage of volatile ether-soluble extractive from the percentage lost during drying. The difference represents the percentage of moisture.

Crude Fiber.—XII. Exhaust a weighed quantity of the prepared drug (paragraph VI), representing about 2 Gm. of the drug, with ether or use the residue from the determination of the volatile ether-soluble extractive (paragraph XIII). Add 200 cc. of boiling sulphuric acid solution, adjusted to exactly 1.25 per cent. by titration, to the ether-exhausted drug, in a 500 cc. flask, and connect the flask with a reflux condenser, the tube of which passes only a short distance below the rubber stopper, into the flask. Heat the mixture to boiling and continue the boiling exactly thirty minutes. Then filter the mixture through a filter and wash the residue on the filter with boiling distilled water until the washings are no longer acid. Rinse the residue back into the flask with 200 cc. of boiling sodium hydroxide solution, adjusted to exactly 1.25 per cent. by titration and free from sodium carbonate. Again heat the mixture to boiling and continue the boiling exactly thirty minutes under the reflux condenser as described under the treatment with acid, then rapidly filter through a tared filter, wash the residue with boiling distilled water until the washings are neutral, dry it at 110° C. until of constant weight, and note the weight. Now completely incinerate the dried residue and weigh the ash: the loss of weight is considered to be the weight of the crude fiber.

NOTE: The boiling with acid and alkali should continue *exactly* thirty minutes from the time that the liquid (which is cooled below the boiling point by adding it to the cold flask) again boils. After the solution has been brought to boiling, the flame should be turned low enough just to maintain boiling. During the boiling the flask should be gently rotated from time to time to catch any particles which may adhere to the walls of the flask. A slow current of air introduced into the flask during the boiling operation will be very helpful to keep down excessive frothing.

Volatile Ether-Soluble Extractive.—XIII. Extract completely 2 Gm. of the prepared drug (paragraph VI), dried over sulphuric acid for not less than twelve hours, by subjecting it, during twenty hours, to the action of dehydrated ether in continuous extraction apparatus. Transfer the ethereal solution to a tared porcelain dish and allow it to evaporate spontaneously. Then dry it over sulphuric acid during eighteen hours and weigh the total ether extract. Now heat the extract gradually up to 110° C. until the weight becomes constant: the loss in weight during the heating represents the volatile portion of the extract.

Non-volatile Ether-soluble Extractive.—XIV. Proceed as directed under *Volatile Ether-soluble Extractive* (paragraph XIII). The weight of the extract after drying in a desiccator and then at 110° C. until of constant weight represents the non-volatile portion of the extract.

Alcohol-soluble Extractive.—XV. Macerate about 2 Gm. of the prepared drug (paragraph VI), accurately weighed, in about 70 cc. of alcohol in a suitable flask. Shake during eight hours at thirty minute intervals and allow to stand for sixteen hours without shaking. Filter and wash the flask and residue with small portions of alcohol until the filtrate measures 100 cc. Evaporate a 50 cc. aliquot portion to dryness in a suitable tared dish on a water bath and dry to constant weight at 110° C. Calculate the percentage of anhydrous extractive from the weight of drug taken.

Diluted Alcohol-soluble Extractive.—XVI. Proceed as directed under paragraph XV, using diluted alcohol instead of alcohol.

Water-soluble Extractive.—XVII. Proceed as directed under paragraph XV, using distilled water instead of alcohol.

Extractive, Soluble in Purified Petroleum Benzin.—XVIII. Extract completely about 2 Gm. of the prepared drug (paragraph VI), accurately weighed, by subjecting it during twenty hours to the action of purified petroleum benzin in a continuous extraction apparatus. Transfer the benzin solution to a tared porcelain dish and allow it to evaporate spontaneously. Then dry it over sulphuric acid for eighteen hours and weigh. Calculate the percentage of anhydrous extractive from the weight of drug taken.

Viscosity

(U. S.)

Viscosity is a term used to denote the relative degree of fluidity of a liquid. Scientifically, viscosity may be defined as the force which will move a unit area of plane surface, with unit speed relative to another parallel plane surface, from which it is separated by a layer of the liquid of unit thickness. The viscosity of a liquid varies with the temperature, the higher the temperature the lower the viscosity and *vice versa*.

Several methods of expressing viscosity are in use. The method adopted in this Pharmacopœia is "kinematic viscosity" which is based on absolute viscosity. The kinematic viscosity is the ratio of the absolute viscosity expressed in poises over the density $\left(\frac{\mu}{\gamma}\right)$. The poise is the unit of absolute viscosity and is equivalent to the force of one "dyne-second per square centimeter."

As a poise is rather large, one-hundredth of a poise, or a centipoise (cp.), is now generally accepted as a more convenient unit for absolute viscosity. The centipoise is almost exactly the viscosity of water at 20° C.

Methods of determining absolute or kinematic viscosity are described in the U. S. Bureau of Standards papers S–298, T–100, and T–112. Instead of the direct determination of absolute or kinematic viscosity which is rather difficult, the viscosity may be determined with either the Engler or Saybolt viscosimeters and the results obtained with these instruments converted into the kinematic viscosity with the aid of the conversion tables given below.

In the Engler instrument, viscosity is expressed in "Engler degrees." These are obtained by dividing the time of discharge for the liquid being tested by the time of discharge for water at 20° C.

With the Saybolt Universal Viscosimeter, results are expressed as the time of discharge, in seconds, of the liquid being tested. In the United States the Saybolt Universal Viscosimeter is generally used for the determination of viscosity of lubricating oils. This instrument, in brief, consists of a metallic cylinder to contain the liquid under examination and having an outlet in the bottom closed with a cork stopper. It is surrounded with a jacket which serves as a bath to heat the liquid under examination to the specified temperature, the jacket being provided with facilities for stirring and heating the bath. Thermometers, a flask graduated at 60 cc., and a stop watch accompany the apparatus.

To determine the viscosity, the bath is first filled with a suitable liquid, and heated to a few degrees above the temperature at which the test is to be made, then the cylinder is filled with the liquid under examination, and when the liquid in the cylinder registers the specified temperature, adjust the volume, place the flask, graduated at 60 cc., under the outlet, and quickly remove the cork, immediately starting the stop watch. When the oil in the flask reaches the 60 cc. mark, stop the watch. The time, in seconds, required to fill the flask to the 60 cc. mark represents the viscosity of the liquid. A fuller description of the apparatus and the details of manipulation are given in the U. S. Bureau of Mines, Technical Paper, 323 A.

Table for Conversion of Saybolt or Engler Viscosity into Kinematic Viscosity

(U. S.)

Column 1 = Viscosity, Saybolt Universal, sec.
Column 2 = Kinematic viscosity, poises divided by Gm. per cc.
Column 3 = Viscosity, Engler degrees.

1	2	3	1	2	3	1	2	3	1	2	3

Vitamine A Assay for Cod Liver Oil

(U. S.)

Cod Liver Oil may be assayed by the following process. When so assayed the Oil should contain at least 50 units per Gm. and must be labelled "This unit is not a measure of the antirachitic activity of Cod Liver Oil." This assay is based upon the estimation of the minimum amount of Cod Liver Oil necessary to meet specific growth-promoting requirements in a standard test animal. The test animals shall be albino rats from a constant source and bred preferably under the control of the experimenter. The vitamine A potency of Cod Liver Oil shall be expressed in units per gramme of oil, the unit to be the minimum daily amount of Cod Liver Oil required to cure induced symptoms of vitamine A starvation in young albino rats, and to cause a gain in weight of from 10 to 20 Gm. within a period of thirty-five days under the conditions of growth and diet specified in this assay.

Place on a vitamine A free diet, rats not less than twenty-five days and not more than twenty-nine days old, and weighing not less than 35 Gm., and not more than 45 Gm. The basal diet is to be composed as follows:

Casein, or desiccated fresh meat, rendered free from vitamine A, ...	18 per cent.
Salt mixture, such as that of Osborne and Mendel[1] or McCollum and Davis,[2].....	4 per cent.
Starch, sufficient to make, ...	100 per cent.

Use sufficient dried brewer's yeast to meet the vitamine B requirements of the animal, mixing it with the basal diet during the vitamine A free period.

The rats shall begin receiving the Cod Liver Oil to be tested after not less than seven days of stationary or declining weight, and from the time of feeding the test oil, they shall be kept in separate cages. The test period shall continue for thirty-five days and the potency of the oil shall be judged from the rat or rats showing a gain on the thirty-fifth day of between 10 and 20 Gm. over the weight at the beginning of the test, and the cure of the induced symptoms of vitamine A starvation.

---

[1] See *J. Bi. Chem.*, 1913, xv, page 317.

[2] See *J. Bi. Chem.*, 1918, xxxiii, page 55.

Each test shall be controlled by at least two standard rats which have received no Cod Liver Oil. These animals may serve as controls for any number of concurrent tests on which the same basal diet is used.

No oil shall be labelled as assayed by the U. S. P. method unless it contains at least 50 units per Gm. of Oil.

The diet for rats used as breeders shall be composed as follows:

Finely ground whole wheat,	66 per cent.
Whole milk powder,	33 per cent.
Sodium chloride,	1 per cent.

The antirachitic requirements of the breeders shall be assured.

Reagents, Test Solutions, Indicators, and Volumetric Solutions

(U. S.)

Reagents are substances used in chemical testing or in microscopic examinations.

Test Solutions, abbreviated "T.S.," are solutions of prescribed strength of reagents in appropriate solvents for use in applying tests.

Indicators are reagents or test solutions employed for the purpose of determining the completion of reactions.

Volumetric Solutions are solutions of reagents of accurately determined strength. The strength is usually related to the molecular weight. These solutions are primarily intended for quantitative estimations.

Some official substances are satisfactory for use as reagents or test solutions if they comply with the tests for purity given in the monographs of the Pharmacopœia. Space is conserved by simply referring to these where such is the case. When a substance is not official or when a greater degree of purity is required than is provided for in the monograph, the substance will be found in the following list, with such description and tests as will insure its suitability for the purpose intended.

Reagents, test solutions, volumetric solutions, and indicators should be preserved in bottles or other containers made of glass of a minimum solubility and low alkalinity, and approximately free from lead or arsenic. The bottles must be capable of being tightly closed with appropriate stoppers. When ground glass stoppers are directed for bottles and apparatus which are to contain substances capable of attacking such surfaces, the ground glass surfaces are to be coated with a thin film of petrolatum. Certain reagents and their solutions are affected by light. In such cases, the direction to keep the substances in amber-colored glass bottles should be carefully observed.

Water, wherever mentioned in carrying out tests or as a solvent in preparing test solutions, etc., is always meant to be distilled water.

The chemical formulas when definitely known, immediately follow the titles of the reagents. This is for convenience and is not to be interpreted as meaning that the reagents are of absolute purity and strength.

Amounts of Substances to be Used in Applying Tests.—When not otherwise stated, it is to be understood that a volume of 10 cc. of an aqueous solution of the designated strength is to be used for a test.

Reagents

Acetic Acid, $CH_3.COOH$.—Use *Acidum Aceticum.*

Acetic Acid, Diluted.—Use *Acidum Aceticum Dilutum.*

Acetic Acid, Glacial, $CH_3.COOH$.—Use *Acidum Aceticum Glaciale.*

Acetic Anhydride, $(CH_3CO)_2O$.—A colorless liquid having a pungent odor. Boiling point, about 137° C. Specific gravity, about 1.075 at 25° C. Non-volatile residue at 110° C. not over 0.005 per cent. An aqueous solution (1 in 50) gives no reaction for *chloride.* One Gm., when dissolved in 50 cc. of distilled water and allowed to stand for one hour in a stoppered flask, requires not less than 19.3 cc. of normal sodium hydroxide for neutralization, using phenolphthalein T.S. as indicator, corresponding to at least 90 per cent. of $(CH_3CO)_2O$.

Preserve in glass-stoppered bottles in a cool, dry place. The stoppers should be sealed with paraffin.

Acetone, CH_3COCH_3.—Use *Acetonum.*

Alcohol, C_2H_5OH.—Use *Alcohol.*

Alcohol, Dehydrated (*Absolute Alcohol*), C_2H_5OH.—Use *Alcohol Dehydratum.*

Alcohol, Neutralized.—To a suitable quantity of alcohol, add 2 or 3 drops of phenolphthalein T.S. and just sufficient fiftieth-normal or tenth-normal sodium hydroxide to produce a slight pink color. Neutralized alcohol should be prepared immediately before using.

Aluminum Metallic, Al.—Aluminum in the form of wire.

Ammonium Carbonate, $NH_4HCO_3.NH_4NH_2CO_2$.—In addition to the description and tests for *Ammonii Carbonas*, it must conform to the following tests: Residue upon incineration not over 0.01 per cent. An aqueous solution (1 in 10) gives no reaction for *chloride, phosphate, sulphate, thiocyanate*, or *heavy metals.*

Ammonium Chloride, NH_4Cl.—In addition to the description and tests for *Ammonii Chloridum*, it must conform to the following tests: Residue upon incineration not over 0.03 per cent. An aqueous solution (1 in 10) gives no reaction for *phosphate, sulphate, thiocyanate*, or *heavy metals.* Ammonium chloride employed in the test for lead under citric and tartaric acids and their salts, must also comply with the following special test. Dissolve 3 Gm. in 10 cc. of distilled water, acidified with 1 drop of reagent hydrochloric acid, in a test tube having an internal diameter of about 20 mm., add 10 cc. of clear, colorless hydrogen sulphide T.S., and mix well. The liquid must show no color when viewed downward against a white background.

Ammonium Nitrate, NH_4NO_3.—Colorless crystals, or white granules, very soluble in water, slightly soluble in alcohol. Residue upon incineration not over 0.03 per cent. An aqueous solution (1 in 10) gives no reaction for *chloride, phosphate, sulphate, thiocyanate*, or *heavy metals.* An aqueous solution (1 in 20) gives no reaction for *nitrite* when tested as follows: To a solution of 1 Gm. of ammonium nitrate in 20 cc. of distilled water add 2 cc. of diluted sulphuric acid and 1 cc. of metaphenylenediamine hydrochloride T.S.: no yellow or yellowish-brown color develops.

Ammonium Oxalate, $(NH_4)_2C_2O_4.H_2O$.—Colorless crystals, soluble in water. Residue, upon incineration, not over 0.03 per cent. An aqueous solution (1 in 25) gives no reaction for *chloride, phosphate, sulphate,* or *heavy metals.*

Ammonium Sulphate, $(NH_4)_2SO_4$.—Colorless crystals or white granules, very soluble in water. Residue upon incineration not over 0.05 per cent. An aqueous solution (1 in 10) gives no reaction for *chloride, phosphate, thiocyanate,* or *heavy metals.*

Ammonium Vanadate, (*Ammonium Metavanadate*), NH_4VO_3.—A white crystalline powder, slightly soluble in water. Easily decomposed upon heating either dry or in solution.

Amyl Alcohol, $C_5H_{11}OH$.—Colorless, oily liquid. Boiling point, 128° to 132° C. Specific gravity, about 0.812 at 25° C. Miscible with alcohol, ether, chloroform, carbon disulphide, petroleum benzin, benzene, and fixed or volatile oils. Slightly soluble in water. Non-volatile residue at 100° C., not over 0.005 per cent.

Aniline, $C_6H_5NH_2$.—A colorless or nearly colorless, strongly refractive, oily liquid. Boiling point, 182° to 184° C. Specific gravity, about 1.020 at 25° C. Soluble in water; miscible with alcohol, ether, and fixed or volatile oils. Five cc. of aniline dissolved in 10 cc. of hydrochloric acid, produces a clear solution. Upon diluting this solution with 15 cc. of distilled water and cooling to 15° C., the liquid does not become more than slightly cloudy.

Preserve in amber-colored bottles. Upon keeping, it often assumes a yellow or brown color, and should then be distilled before using.

Aniline Sulphate, $(C_6H_5NH_2)_2H_2SO_4$.—White or nearly white crystals, very soluble in water, slightly soluble in alcohol.

Arsenic Trioxide, As_2O_3.—Use *Arseni Trioxidum.*

Asbestos.—The silky, well-matted variety of long-fiber asbestos. When moistened and rolled between the thumb and finger, it forms a compact mass. For use as a filtering medium for the Gooch crucible, boil the asbestos for one hour with diluted hydrochloric acid, and wash it with boiling distilled water until free from all acid.

Barium Chloride, $BaCl_2.2H_2O$.—Colorless crystals, freely soluble in water, slightly soluble in alcohol and in concentrated hydrochloric acid. An aqueous solution (1 in 20) is neutral and gives no reaction for *nitrate, chlorate,* or *heavy metals.* Dissolve 2 Gm. of barium chloride in 100 cc. of distilled water, add a few drops of hydrochloric acid, heat to boiling, then add 20 cc. of diluted sulphuric acid, and set aside for at least twelve hours. Filter, evaporate the filtrate, and ignite. The weight of the residue does not exceed 0.002 Gm. (*other fixed bases*). Shake 1 Gm. of finely powdered barium chloride with 20 cc. of dehydrated alcohol during five minutes, filter, evaporate the filtrate, and ignite. The weight of the residue does not exceed 0.002 Gm. (*strontium and calcium*).

Barium Hydroxide, $Ba(OH)_2.8H_2O$.—Colorless crystals, soluble in water, very soluble in boiling water. An aqueous solution (1 in 20) gives no reaction for *chloride* or *heavy metals.* Dissolve 2 Gm. of barium hydroxide in 100 cc. of distilled water, add 5 cc. of hydrochloric acid, heat to boiling, then add 15 cc. of diluted sulphuric acid, and set aside for at least twelve hours. Filter, evaporate the filtrate, and ignite. The weight of the residue does not exceed 0.003 Gm. (*other fixed bases*).

Assay.—One Gm. dissolved in distilled water, and titrated with normal hydrochloric acid, using methyl orange T.S. as indicator, shows not less than 99 per cent. of $Ba(OH)_2.8H_2O$.

Preserve in tightly-stoppered containers to prevent access of carbon dioxide.

Barium Nitrate, $Ba(NO_3)_2$.—Colorless crystals, soluble in water, freely soluble in boiling water. An aqueous solution (1 in 20) gives no reaction for *heavy metals* and meets the requirements of the test for *other fixed bases* under *barium chloride.* Converted into chloride by twice evaporating to dryness with hydrochloric acid, it meets the requirements of the tests for *strontium* and *calcium* under *barium chloride.*

Benzene (*Benzol*), C_6H_6.—A colorless, transparent liquid. Boiling point, 79° to 81° C. Congealing point, about 5° C. Specific gravity, about 0.876 at 25° C. Insoluble in water, miscible with alcohol, ether, and with fixed or volatile oils. When equal volumes of benzene and sulphuric acid are shaken together in a glass cylinder during fifteen minutes, the acid upon separation is not colored. Add a few mgm. of isatin, shake well, and allow to stand for thirty minutes. The acid does not acquire a blue or green color (*thiophene*). Non-volatile residue at 100° C., not over 0.01 per cent.

Benzidine (*Paradiaminodiphenyl*), $(C_6H_4NH_2)_2$.—A white or slightly reddish crystalline powder. Sparingly soluble in cold water, slightly soluble in boiling water, alcohol, and ether. Melting point, about 128° C. A solution (1 in 50) in 2 per cent. hydrochloric acid gives no reaction for *sulphate.* Residue upon incineration not over 0.05 per cent.

Benzin, Petroleum.—Use *Benzinum Purificatum.*

Betanaphthol, $C_{10}H_7OH$.—Use *Betanaphthol.*

Bromine, Br.—A dark reddish-brown fuming, corrosive volatile liquid containing not less than 99 per cent. of Br and not more than 1 per cent. of Cl. Specific gravity, about 3.1 at 25° C. Soluble in about 30 parts of water, soluble in alcohol and in ether (with gradual decomposition of the solvents). Dissolve about 1 cc. of bromine in 50 cc. of sodium hydroxide T.S. and allow to stand for six hours: the solution remains clear (*organic bromine compounds*). Agitate 10 cc. of a saturated aqueous solution of bromine with 1 Gm. of reduced iron until the solution is nearly colorless. Filter and add 1 cc. of starch T.S. and 1 cc. of ferric chloride T.S.: no blue color develops (*iodine*). Non-volatile residue at 100° C., not over 0.01 per cent.

Assay.—Dissolve 10 Gm. of potassium iodide in 25 cc. of distilled water, introduce the solution into a 100 cc. measuring flask, stopper, and determine accurately the weight of the flask and its contents. Add about 1 Gm. of bromine to the contents of the flask, determine its exact weight, then fill the flask to the mark with distilled water, and titrate 25 cc. of this solution with tenth-normal sodium thiosulphate, using starch T.S. as indicator. Each Gm. of bromine (containing not more than 1 per cent. of chlorine) corresponds to not more than 126.7 cc. of tenth-normal sodium thiosulphate. Preserve in glass-stoppered bottles, in a cool place, the bottles being enclosed in larger vessels with the space between filled with some substance, capable of absorbing bromine.

Cadmium and Potassium Iodide.—A mixture of equal weights of cadmium iodide and potassium iodide. An aqueous solution (1 in 20) shows no *free iodine.*

Cadmium Chloride, $CdCl_2.2H_2O$.—Small, colorless crystals, efflorescent in dry air. Very soluble in water, soluble in alcohol.

Cadmium Iodide, CdI_2.—Colorless crystals, becoming yellow upon exposure to light and air. Very soluble in water and in alcohol, sparingly soluble in ether and acetone.

Calcium Carbonate, $CaCO_3$.—Use *Calcii Carbonas Præcipitatus.*

Calcium Chloride, $CaCl_2.2H_2O$.—In addition to the description and tests for *Calcii Chloridum*, page 252, it must conform to the following tests: One Gm. dissolves completely in 10 cc. of alcohol. An aqueous solution (1 in 20) is neutral to litmus paper, does not respond to the test for *heavy metals*, and yields no precipitate with an equal volume of calcium sulphate T.S. (*barium*). One Gm. of calcium chloride shows no *ammonia* when warmed with sodium hydroxide, and 0.5 Gm. meets the requirements of the test for *arsenic.* Precipitate the calcium from 1 Gm. of the salt dissolved in 50 cc. of distilled water by ammonium oxalate T.S., evaporate and ignite the filtrate: the residue does not exceed 0.3 per cent. (*alkali* and *magnesium salts*).

Calcium Chloride, Fused, $CaCl_2$.—Deliquescent lumps or granules. It complies with the test for identity and purity under *Calcii Chloridum*, and when assayed by the method given under that substance shows not less than 98 per cent. of $CaCl_2$.

Calcium Sulphate, $CaSO_4.2H_2O$.—Transparent crystals, crystalline masses or a white powder. Slightly soluble in water.

Canada Turpentine.—A liquid oleoresin from *Abies balsamea* (Linné) Miller (Fam. *Pinaceæ*). A pale yellow or greenish, viscid, transparent liquid. Completely soluble in ether, chloroform, and benzene. When exposed to the air, Canada turpentine gradually dries and remains transparent. Canada turpentine solidifies when mixed with 20 per cent. of its weight of magnesium oxide, previously moistened with water.

Carbon Disulphide, CS_2.—A clear, colorless, very volatile, inflammable liquid. Boiling point, about 46° C. Specific gravity, about 1.26 at 25° C. Slightly soluble in water, very soluble in alcohol, ether, chloroform and fixed or volatile oils. Carbon disulphide does not affect the color of blue litmus paper moistened with water (*sulphur dioxide*). Agitate 10 cc. of carbon disulphide with 0.5 Gm. of lead carbonate: the latter should not acquire a brown color (*foreign sulphur compounds*). Non-volatile residue at 100° C., not over 0.004 per cent.

Carbon Tetrachloride, CCl_4.—Use *Carbon Tetrachloridum.*

Casein.—A white or slightly yellow, odorless, granular powder. Insoluble in water and other neutral solvents, but readily dissolved by ammonia T.S. and by solutions of alkali hydroxides, forming a cloudy solution. Ash: not more than 1 per cent. Loss on drying at 100° C., not more than 10 per cent. Shake 1 Gm. of casein with 20 cc. of distilled water for ten minutes and filter: the filtrate is not alkaline to litmus paper, and on evaporating to dryness and drying at 100° C., the residue does not exceed 0.1 per cent (*soluble substances*). Dissolve 1 Gm. of casein in 10 cc. of distilled water, with 5 cc. of alcoholic ammonia T.S., and shake out with two successive portions of 20 cc. each of purified petroleum benzin. Evaporate the benzin extract at a low temperature and dry at 70° C. The weight of the residue does not exceed 0.5 per cent. (*fats*). Anhydrous casein contains from 15.2 to 16 per cent. of nitrogen, using the Kjeldahl method.

Charcoal.—Use *Carbo Ligni.*

Chloral Hydrate, $CCl_3CHO.H_2O$.—Use *Chloralis Hydras.*

Chlorinated Lime.—Use *Calx Chlorinata.*

Chloroform, $CHCl_3$.—Use *Chloroformum.*

Chromium Trioxide, CrO_3.—Use *Chromii Trioxidum.*

Cobaltous Chloride, (*Cobalt Chloride*) $CoCl_2.6H_2O$.—Red crystals or a red, crystalline powder. Very soluble in water and in alcohol, soluble in acetone and in glycerin. Dissolve 2 Gm. of cobaltous chloride in 100 cc. of distilled water. Completely precipitate the cobalt by the addition of an excess of ammonia T.S., followed by ammonium sulphide T.S., and filter. The filtrate, after evaporation and ignition, leaves not more than 0.008 Gm. of residue (*salts of alkalies* and *alkali earths*). Dissolve 1 Gm. of cobaltous chloride in 20 cc. of distilled water, add 3 Gm. of sodium cyanide, and boil until the solution acquires a yellow color. Filter, add 1 cc. of bromine and sufficient sodium hydroxide T.S. to render strongly alkaline: no brown color develops (*nickel*). A solution of cobaltous chloride (1 in 20) strongly acidulated with hydrochloric acid, yields no dark precipitate with hydrogen sulphide (*lead* or *copper*).

Copper, Cu.—Copper in the form of wire, foil, turnings, filings, or granules. It should give no reaction for *antimony, lead, silver,* or *tin.* It should contain not more than 0.03 per cent. of *iron* and not more than 0.0001 per cent. of *arsenic.*

Cupric Acetate, $Cu(C_2H_3O_2)_2.H_2O$.—Bluish-green crystals, or powder, having an acetous odor. Soluble in water, slightly soluble in alcohol. It should contain not more than 0.01 per cent. of *sulphate* or *chloride.* Dissolve 1 Gm. of cupric acetate in 100 cc. of distilled water, add 1 cc. of hydrochloric acid, completely precipitate the copper with hydrogen sulphide, filter, evaporate the filtrate to dryness, and gently ignite: the residue does not exceed 0.5 per cent.

Cupric Sulphate, $CuSO_4.5H_2O$.—Use *Cupri Sulphas.*

Cupric Sulphate, Anhydrous, $CuSO_4$.—A white or grayish-white powder, free from a blue tinge. Upon adding a small quantity of water, it becomes blue. It is soluble in water and responds to the reactions characteristic of copper and sulphates. An aqueous solution (1 in 50) yields no immediate reaction for *chloride.* Precipitate the copper from a solution of 2 Gm. in 100 cc. of distilled water, acidulated with 2 cc. of hydrochloric acid, with hydrogen sulphide and filter. Evaporate the filtrate to dryness and gently ignite: the residue does not exceed 0.1 per cent.

Curare.—The composition of curare is not definitely known, and different specimens vary, depending upon the special variety of plant used in its manufacture. The most important source of curare is the bark of several varieties of *Strychnos*, the species most commonly employed being *S. Castelnæi* Wedd., *S. Toxifera* Benth., or *S. Crevauxii* G. Planch. (Fam. *Loganiaceæ*). Commercial curare is a brownish or black, shining resinoid mass. About 75 per cent. is soluble in cold water and it is almost completely soluble in diluted alcohol.

Dextrose, $C_6H_{12}O_6.H_2O$.—Use *Dextrosum.*

Dichloramine, $C_7H_7O_2NSCl_2$.—Use *Dichloramina.*

Diphenylamine, $(C_6H_5)_2NH$.—Grayish-white or colorless crystals. Melting point, about 54° C. Slightly soluble in water and in alcohol. A solution of 0.2 Gm. in 20 cc. of sulphuric acid, is colorless (*nitrates*). No violet color results when 1 Gm. of powdered diphenylamine is added to 20 cc. of a saturated aqueous solution of chlorinated lime (*aniline*).

Epinephrine, $C_9H_{13}O_3N$.—Use *Epinephrina.*

Ether, Dehydrated, $(C_2H_5)_2O$.—It conforms to the description and tests for *aldehyde* and *peroxide,* page 80, and to the following: Specific gravity, not over 0.711 at 25° C. Boiling point, from 34° to 36° C. To 10 cc. of ether, contained in a dry, clean, glass cylinder, add 0.1 Gm. of rosaniline acetate: no coloration results (*water* or *alcohol.*) Non-volatile residue at 100° C., not more than 0.002 per cent.

Ethyl Acetate, $CH_3COOC_2H_5$.—A transparent, colorless, inflammable liquid. Soluble in water, miscible with alcohol, ether, and fixed or volatile oils. Boiling point, 75° to 77° C. Specific gravity: 0.893 to 0.898 at 25° C. Ethyl acetate does not redden moistened blue litmus paper. Evaporate 5 cc. of ethyl acetate from clean, odorless, unsized paper. The final odor is not different in character from that observed at the beginning of the test. Superimpose 5 cc. of ethyl acetate upon 5 cc. of sulphuric acid: no dark coloration is produced at the zone of contact (*readily carbonizable substances*). Non-volatile residue at 100° C., not more than 0.005 per cent.

Ferric Ammonium Sulphate, $FeNH_4(SO_4)_2.12H_2O$.—Pale violet crystals. Efflorescent on exposure to air. Very soluble in water, insoluble in alcohol. An aqueous solution (1 in 20) gives no reaction for *chloride* or *ferrous salts.*

Ferric Chloride, $FeCL_3.6H_2O$.—Use *Ferri Chloridum.*

Ferrous Sulphate, $FeSO_4.7H_2O$.—Use *Ferri Sulphas.*

Ferrous Sulphide, FeS.—Dark gray or grayish-black lumps, fragments, sticks, granules, or globules. It is insoluble in water but is dissolved by diluted sulphuric or diluted hydrochloric acid with copious evolution of hydrogen sulphide.

Filter Paper, Quantitative.—For the Mercuric Bromide Test Paper of the Arsenic Test, use Schleicher and Schull's No. 589 (Blue Ribbon), or Swedish O. filter paper, or other makes of like surface, quality and ash (see *Arsenic Test*).

Fluorescein (*Resorcinolphthalein*), $C_{20}H_{12}O_5$.—A yellowish-red to dark red powder. Sparingly soluble in water and in ether, soluble in alcohol. Fluorescein dissolves in solutions of the alkali hydroxides or carbonates, forming a solution which has a bright green fluorescence. Ash, not over 0.25 per cent. Agitate about 1 Gm. of fluorescein with 20 cc. of distilled water and filter. One drop of tenth-normal sodium hydroxide imparts to 10 cc. of the filtrate a bright green fluorescence. The addition of a drop of ferric chloride T.S. to the remaining portion of the filtrate does not produce a bluish coloration (*resorcinol* or *other phenolic compounds*).

Fuchsin, Basic (*Basic Fuchsin, Rosaniline, Rosaniline Acetate, Rosaniline Hydrochloride*).—Crystals or crystalline fragments with a glossy, greenish-bronze luster. Soluble in water, alcohol, and amyl alcohol, An aqueous solution (1 in 500) yields a red precipitate upon the addition of tannic acid T.S. To 10 cc. of an aqueous solution (1 in 500), add 10 cc. of ammonia T.S. and 0.5 Gm. of zinc dust, and agitate. Decolorization of the solution results. Place a few drops of this decolorized solution upon filter paper, then place near by, on the paper, a few drops of hydrochloric acid. The zone of contact assumes a red color. Ash: not over 0.25 per cent.

Gallic Acid, $HC_7H_5O_5.H_2O$.—White or nearly white crystals. A cold, saturated aqueous solution of gallic acid neither colors nor precipitates solutions of pure ferrous salts, and does not produce a precipitate with gelatin T.S. (*tannic acid*).

Gelatin.—Use *Gelatinum.*

Glass Wool.—Fine threads of glass. Glass wool should yield not more than 0.5 per cent. of soluble matter when boiled for one-half hour with diluted hydrochloric acid. Boil 1 Gm. of glass wool for five minutes with a mixture of 25 cc. each of diluted nitric acid and distilled water, filter, evaporate the filtrate to dryness, treat the residue with 10 cc. of distilled water, and again filter. This latter filtrate is not colored by the addition of an equal volume of hydrogen sulphide T.S. (*lead*).

Gold Chloride (*Chlorauric Acid*), $HAuCl_4.4H_2O$.—Yellow, hygroscopic crystals. Very soluble in water, soluble in alcohol and in ether. An accurately weighed portion of about 0.1 Gm., when moistened with a slight excess of ammonium oxalate T.S., evaporated to dryness, ignited, and weighed, yields a residue of about 48 per cent. of metallic gold. Heat the metallic gold thus obtained with diluted hydrochloric acid and filter. The filtrate gives no appreciable coloration with either hydrogen sulphide T.S. or ammonium sulphide T.S. (*other metals*).

Hematein, $C_{16}H_{12}O_6$.—A product of the oxidation of hematoxylin. Reddish-brown crystalline plates of a greenish metallic luster. Sparingly soluble in water, alcohol and in ether, insoluble in chloroform. It is dissolved by ammonia T.S. with a brownish-violet color and by dilute solutions of caustic alkalies with a bright red color.

Hydrochloric Acid, HCl.—Use *Acidum Hydrochloricum.*

Hydrochloric Acid, Concentrated, HCl.—In addition to the description and identity tests for *Acidum Hydrochloricum,* it must conform to the following tests: Specific gravity, between 1.170 and 1.184 at 25° C., corresponding to from 35 to 38 per cent. of HCl. Non-volatile residue, upon evaporation and ignition with a drop of sulphuric acid, not more than 0.002 per cent. Evaporate 100 cc. of concentrated hydrochloric acid to about 5 cc., dilute with 10 cc. of distilled water, and add 5 drops of barium chloride T.S.: no precipitate occurs within twelve hours (*sulphate*). Add 5 cc. of concentrated hydrochloric acid, diluted with 50 cc. of distilled water, to a solution of 1 drop of tenth-normal iodine in 50 cc. of distilled water to which a few drops of starch T.S. have been added: no decolorization occurs (*sulphur dioxide*). Dilute 10 cc. of the acid with about 100 cc. of distilled water at a temperature of about 50° C. and thoroughly saturate it with hydrogen sulphide: no dark coloration or precipitate forms either before or after rendering alkaline with ammonia T.S. and adding 5 drops of ammonium sulphide T.S. (*heavy metals*). Two cc. of concentrated hydrochloric acid, diluted with 10 cc. of distilled water, when subjected to the arsenic test, page 1533, produces a stain not greater than that produced by the zinc alone.

Hydrochloric Acid, Diluted.—Use *Acidum Hydrochloricum Dilutum.*

Hydrogen Sulphide, H_2S.—A gas generated by treating ferrous sulphide with diluted sulphuric or hydrochloric acid.

Indicators.—See page 1566.

Indigo Carmine, $C_{16}H_8O_2N_2(SO_3Na)_2$.—Use *Sodii Indigotindisulphonas.*

Iodine, Purified, I.—Prepared from *Iodum,* page 584, as follows: Powder a suitable quantity of iodine and place it in a porcelain dish. Heat it over a water bath for twenty minutes, stirring constantly with a glass rod to vaporize moisture and other impurities. Then transfer the iodine to a glass, porcelain, or wedgewood mortar and triturate with about 5 per cent. of its weight of potassium iodide. Return the mixture to the dish, cover it with a glass funnel, and heat carefully on a sand bath to sublime the iodine. When the operation is completed, detach the sublimed iodine, powder it, and dry it over calcium chloride in a desiccator for twenty-four hours: the ash from 2 Gm. is negligible.

Preserve in well-closed, glass-stoppered bottles, in a cool place.

Iron, Fe.—Bright, clean iron in the form of wire, sheet, filings, or powder. In the test for copper, use bright pieces of sheet iron or steel knitting needles.

Preserve iron in well-closed glass containers to protect it from moist air, acid fumes, etc.

Isatin, $C_8H_5NO_2$.—Small yellowish-red crystals; slightly soluble in water, soluble in alcohol, and in ether. Melting point about 200° C. Aqueous alcoholic or ethereal solutions of isatin are reddish-brown in color.

When isatin is dissolved in a solution of an alkali hydroxide, it yields a violet colored solution which upon heating or upon long standing becomes yellow.

Kerosene.—A mixture of hydrocarbons, chiefly of the methane and naphthene series. It is a clear, colorless, or only slightly colored liquid, having a characteristic but not disagreeable odor. Specific gravity about 0.80 at 25° C. Boils between 180° and 300° C. Prepare purified kerosene by shaking a convenient volume of kerosene twice with about one-tenth its volume of 15 per cent. sodium hydroxide solution, then wash with distilled water until free from alkali.

Lead Acetate, $Pb(C_2H_3O_2)_2.3H_2O$.—Use *Plumbi Acetas.*

Lead Carbonate, $(PbCO_3)_2.Pb(OH)_2$.—A white, heavy powder. Insoluble in water and in alcohol. It is dissolved by acetic or diluted nitric acid with effervescence, the resulting solutions responding to the identity tests for lead.

Lead Monoxide, PbO.—Use *Plumbi Monoxidum.*

Lead Nitrate, $Pb(NO_3)_2$.—Colorless or white crystals or a white crystalline powder. Very soluble in water, almost insoluble in alcohol. Lead nitrate responds to the identity tests for lead, and nitrates, and meets the requirements of the tests for *foreign metals* under *Plumbi Acetas.*

Lead Peroxide (*Lead Dioxide*), PbO_2.—A dark brown powder containing not less than 90 per cent. of PbO_2. Insoluble in water and in alcohol. It is unaffected by nitric acid, but is decomposed by hydrochloric acid with the evolution of chlorine, and by hot sulphuric acid with the evolution of oxygen. It is dissolved by concentrated solutions of alkali hydroxides. Boil 2 Gm. of lead peroxide with 50 cc. of distilled water for fifteen minutes, filter, evaporate the filtrate to dryness and ignite. The residue does not exceed 0.5 per cent. (*soluble salts*).

Assay.—Dissolve about 0.5 Gm. of finely powdered lead peroxide, previously dried to constant weight at 100° C. and accurately weighed, in a solution made by mixing 1.5 Gm. of potassium iodide, 12 Gm. of sodium acetate, 8 cc. of glacial acetic acid, and 8 cc. of distilled water. Clear the solution if necessary by the further addition of sodium acetate, and then determine the liberated iodine by titration with tenth-normal sodium thiosulphate, starch T.S. being used as indicator. Each cc. of tenth-normal sodium thiosulphate corresponds to 0.01195 Gm. of PbO_2.

Lime, Freshly Slaked, $Ca(OH)_2$.—To prepare freshly slaked lime, drop upon a convenient quantity of lime, page 263, one-third of its weight of water, cover and allow it to stand until it has been converted to a pulverulent mass and is cool. Freshly slaked lime, after drying and igniting, yields not more than 0.1 per cent. of residue insoluble in hydrochloric acid and should show practically no effervescence when dissolved.

Magnesium Chloride, $MgCl_2.6H_2O$.—White, deliquescent crystals, very soluble in water. An aqueous solution is neutral to litmus paper. Two Gm. of magnesium chloride should completely dissolve in 10 cc. of 85 per cent. alcohol. Magnesium chloride also complies with the tests for *barium, calcium, heavy metals,* and *sulphate,* under reagent sodium chloride.

Magnesium Oxide, MgO.—Use *Magnesii Oxidum.*

Magnesium Sulphate, $MgSO_4.7H_2O$.—Use *Magnesii Sulphas.*

Manganese Dioxide, MnO_2.—A fine heavy black powder, containing not less than 85 per cent. of MnO_2. It is insoluble in water, but is dissolved by hydrochloric acid with the evolution of chlorine.

Assay.—Dissolve about 0.2 Gm. of manganese dioxide, accurately weighed, in a mixture of 50 cc. of tenth-normal oxalic acid and 3 cc. of sulphuric acid, heat to about 80° C., and titrate the excess of oxalic acid with tenth-normal potassium permanganate. Each cc. of tenth-normal oxalic acid represents 0.0043465 Gm. of MnO_2.

Manganese Sulphate, $MnSO_4.4H_2O$ or $MnSO_4.5H_2O$.—Pink crystals. Very soluble in water, insoluble in alcohol. An aqueous solution (1 in 50) gives no reaction for *chloride* or *iron.* Dissolve 1 Gm. of manganese sulphate in 50 cc. of distilled water, add 10 cc. of ammonium chloride T.S., heat to boiling, and precipitate the manganese with a slight excess of ammonium sulphide T.S. Continue the heating until the precipitate assumes a greenish color, then filter, evaporate the filtrate to dryness, and ignite; not more than 0.5 per cent. of residue remains (*salts of foreign metals*).

Mercuric Bromide, $HgBr_2$.—White needles, prisms, lustrous scales, or a granular, crystalline powder. Slightly soluble in cold water, soluble in boiling water and in alcohol. Mercuric bromide should be completely soluble in hot water. Residue upon incineration, not more than 0.05 per cent.

Mercuric Chloride, $HgCl_2$.—Use *Hydrargyri Chloridum Corrosivum.*

Mercuric Oxide, Red, HgO.—An orange-red crystalline powder. Insoluble in water but dissolved by dilute nitric or dilute hydrochloric acid. A solution (1 in 50) in diluted nitric acid gives no reaction for *chloride* or *sulphate.* One Gm. mixed with 10 cc. of diluted sulphuric acid should give no reaction for nitrate with ferrous sulphate. Residue upon incineration, not more than 0.2 per cent. When dried to constant weight at 100° C. and assayed electrolytically or by titration with tenth-normal potassium thiocyanate, it should show not less than 99.5 per cent. of HgO.

Mercurous Chloride, Mild, HgCl.—Use *Hydrargyri Chloridum Mite.*

Mercury, Hg.—Use *Hydrargyrum.*

Metaphenylenediamine Hydrochloride, $C_6H_4(NH_2)_2.2HCl$.—A white or slightly reddish-white, crystalline powder, easily soluble in water. An aqueous solution (1 in 200) should be colorless.

Molybdic Acid.—A white or yellowish-white powder of somewhat variable composition, containing, when assayed by the lead molybdate method, not less than 83 per cent. of MoO_3. It is insoluble in water, soluble in solutions of alkali hydroxides. No insoluble residue should remain when 1 Gm. of molybdic acid is dissolved in 10 cc. of ammonia T.S. The addition of 10 cc. of hydrogen sulphide T.S. produces a greenish-yellow color but no brownish-yellow color or precipitate (*heavy metals*). Dissolve 10 Gm. of molybdic acid in 25 cc. of ammonia T.S., pour this solution gradually and with constant stirring into a mixture of 75 cc. of nitric acid and 75 cc. of distilled water, and set the solution aside for at least twelve hours at 40° C.: no yellow precipitate should appear (*phosphate*).

Naphthylamine (Alpha) Hydrochloride, $C_{10}H_7NH_2.HCl$.—A white, crystalline powder which turns bluish upon exposure to light and air. Insoluble in water, soluble in alcohol and in ether. An aqueous solution (1 in 100) in diluted acetic acid gives a violet color with 5 drops of ferric chloride T.S. An aqueous solutiod (1 in 40) in diluted acetic acid should be colorless and not more than slightly opalescent from undissolven matter. Non-volatile residue upon incineration, not more than 0.05 per cent.

Naphthylamine (Beta) Acetate, $C_{10}H_7NH_2.C_2H_4O_2$.—White to yellowish-white, crystalline scales or flakes. Slightly soluble in water, soluble in alcohol. An aqueous solution (1 in 100) does not give a violet color with 5 drops of ferric chloride T.S. (*alpha naphthylamine.*

Nitric Acid, HNO_3.—Use *Acidum Nitricum.*

Nitric Acid, Diluted.—Use a 10 per cent. aqueous solution of HNO_3.

Nitric Acid, Fuming.—A yellowish-red to brownish-red fuming liquid. Specific gravity, about 1.50 at 25° C. It conforms to the tests for purity under *Acidum Nitricum,* page 42, omitting the assay.

Preserve carefully in glass-stoppered bottles, in a cool place.

Oil of Cedar Wood.—For clearing microscopic sections, a selected commercial distilled oil from the wood of the red cedar, *Juniperus virginiana* Linné (Fam. *Pinaceæ*), should be used. Refractive index, about 1.504 at 20° C. For use with homogeneous immersion lenses, a specially prepared oil is required, having a refractive index of exactly 1.515 at 18° C.

Ouabain, $C_{30}H_{46}O_{12}.xH_2O$.—Ouabain, crystallized from a mixture of alcohol and ether, contains approximately 12½ per cent. of water, and requires a temperature of 130° C. for rapid and complete dehydration. The optical properties are as follows: In ordinary light—colorless rods. In parallel polarized light with crossed nicols extinction is parallel. The double refraction is strong. The sign of elongation is +. Refractive indices $\left(\frac{20^\circ}{D}\right)$: $\alpha = 1.540$ (crosswise), $\gamma = 1.580$ (lengthwise), both ± 0.002.

The specific rotation of anhydrous ouabain: $\left(\alpha\right)^{20}_{D} = -31.3^\circ$ to -31.9°.

Ouabain is stable at 130° C. Anhydrous ouabain, whether originally crystallized from alcohol and ether or from water at room temperature, begins to soften at about 180° C.

Oxalic Acid, $H_2C_2O_4.2H_2O$.—Colorless, uneffloresced crystals. Soluble in water, very soluble in boiling water and in alcohol. Dissolve 2 Gm. of oxalic acid in 30 cc. of distilled water, add 2 Gm. of sodium hydroxide, and treat with 1 cc. of Nessler's reagent: it shows no darker coloration than a blank test from which the oxalic acid has been omitted (*ammonium compounds*). An aqueous solution (1 in 20) gives no reaction for *chloride, sulphate, nitrate,* or *heavy metals.* Residue upon incineration, not over 0.05 per cent. Preserve in well-stoppered bottles.

Palladous Chloride, $PdCl_2$.—A dark brown, hygroscopic powder, yielding a turbid solution with water in consequence of the formation of a basic salt.

Phenol, C_6H_5OH.—Use *Phenol.*

Phenylhydrazine, $C_6H_5.NH.NH_2$.—A colorless or slightly yellowish, highly refractive liquid. Boiling point, about 242° C., congealing when cold to crystalline plates which melt at 19° C. Slightly soluble in water, soluble in alcohol and in ether. Its aqueous solution soon becomes dark from oxidation. Shake 2 cc. of phenylhydrazine with 20 cc. of 5 per cent. acetic acid: a clear liquid results.

Phloroglucinol, $C_6H_3(OH)_3.2H_2O$.—White or yellowish-white crystals or a crystalline powder. Slightly soluble in water, soluble in alcohol and in ether. When rapidly heated, it melts between 217° and 219° C. When slowly heated, it melts at a much lower temperature. Add 0.1 Gm. of phloroglucinol to 1 cc. of acetic anhydride and 1 cc. of sulphuric acid in a test tube, and heat in a bath of boiling water for ten minutes: no blue color develops (*diresorcinol*).

Phosphoric Acid, H_3PO_4.—Use *Acidum Phosphoricum.*

Phosphotungstic Acid, approximately $P_2O_5.24WO_3.xH_2O$.—White or yellowish-green crystals or a crystalline powder. Soluble in water and in alcohol. Slightly soluble in ether. To a solution of 1 Gm. of phosphotungstic acid in 10 cc. of distilled water, add 0.1 Gm. of sodium chloride and 3 drops of indigo carmine T.S., then cautiously add 10 cc. of sulphuric acid, and allow the liquid to stand for ten minutes: the blue color does not disappear (*nitrate*). An aqueous solution (1 in 10) gives no reation for *ammonium salts.*

Picric Acid, $C_6H_2(OH)(NO_2)_3$.—Use *Trinitrophenol.*

Platinic Chloride (*Chloroplatinic Acid*), $H_2PtCl_6.6H_2O$.—A brownish-red, very hygroscopic, crystalline mass. Very soluble in water, soluble in alcohol and in ether. It dissolves completely in 10 parts of water or alcohol, forming yellow solutions. The residue, upon incineration in a porcelain crucible, is not less than 37.6 per cent. When this residue is treated with 50 times its weight of diluted nitric acid for fifteen minutes on a water bath, the acid solution, upon filtration, evaporation to dryness and incineration, yields a residue not exceeding 0.15 per cent. of the platinic chloride taken.

Potassium and Sodium Tartrate, $KNaC_4H_4O_6.4H_2O$.—Use *Potassii et Sodii Tartras.*

Potassium Acetate, $KC_2H_3O_2$.—Use *Potassii Acetas.*

Potassium Bicarbonate, $KHCO_3$.—Use *Potassii Bicarbonas.*

Potassium Bisulphate, $KHSO_4$.—Fused white, deliquescent masses or granules. Reaction acid. Freely soluble in water. It responds to the identity tests for potassium and for sulphates.

Potassium Bitartrate, $KHC_4H_4O_6$.—In addition to the tests described under *Potassii Bitartras,* page

876, it gives no reaction for *chloride, sulphate, calcium, ammonium compounds,* or *heavy metals.* Heat 5 Gm. of potassium bitartrate at 100° C. for thirty minutes: no loss of weight should result. Dissolve 5 Gm. of potassium bitartrate, accurately weighed, in 250 cc. of hot distilled water, heat to boiling, and titrate with normal sodium hydroxide, phenolphthalein T.S. being used as indicator: it shows not less than 99.9 per cent. and not more than 100 per cent. of $KHC_4H_4O_6$.

Potassium Bromate, $KBrO_3$.—White crystals or a granular powder. Soluble in water, slightly soluble in alcohol. An aqueous solution (1 in 20) is neutral and should not at once acquire a yellow color upon the addition of 3 drops of diluted sulphuric acid (*bromide*).

Assay.—When dried to constant weight at 100° C. and assayed by titration with tenth-normal sodium thiosulphate, after adding potassium iodide and hydrochloric acid, it shows not less than 99.8 per cent. of $KBrO_3$. Each cc. of tenth-normal sodium thiosulphate corresponds to 0.002784 Gm. of $KBrO_3$.

Potassium Carbonate, $K_2CO_3.xH_2O$.—Use *Potassii Carbonas.*

Potassium Carbonate, Anhydrous, K_2CO_3.—White granules or powder, very hygroscopic. Very soluble in water with the evolution of heat. When heated to redness, it should not lose more than 1 per cent. of its weight (*water*). It meets the requirements of the tests for identity and purity under *Potassii Carbonas,* making allowance for the difference in water content.

Potassium Chlorate, $KClO_3$.—Use *Potassii Chloras.*

Potassium Chloride, KCl.—Colorless crystals or a white, granular powder. It is odorless. Freely soluble in water, slightly soluble in alcohol. Its aqueous solution (1 in 10) is neutral to litmus paper, and imparts to a non-luminous flame not more than a slight transient yellow color (*sodium*). To a solution of 1 Gm. of the salt in 5 cc. of distilled water, add an equal volume of sulphuric acid and 1 drop of indigo T.S.: the blue color does not disappear (*nitrate*). Potassium chloride also complies with the tests for *barium, sulphate, magnesium, calcium, heavy metals,* and *ammonia* under *Reagent Sodium Chloride.*

Potassium Chromate, K_2CrO_4.—Yellow crystals, very soluble in water, insoluble in alcohol. An aqueous solution (1 in 20) is not reddened by phenolphthalein T.S. An aqueous solution (1 in 20) gives no reaction for *aluminum* or *calcium.* Ten cc. portions of an aqueous solution (1 in 20), acidulated respectively with 5 cc. of nitric acid and 3 cc. of hydrochloric acid, give no reaction for *chloride* or *sulphate.*

Potassium Citrate, $K_3C_6H_5O_7.H_2O$.—Use *Potassii Citras.*

Potassium Dichromate, $K_2Cr_2O_7$.—Dark yellowish-red crystals or crystalline granules. Soluble in water. An aqueous solution (1 in 20) should give no reaction for *aluminum* or *calcium.* Twenty cc. portions of an aqueous solution (1 in 20), treated respectively with 5 cc. of nitric acid and 2 cc. of hydrochloric acid, should give no reaction for *chloride* and no reaction for *sulphate* within eighteen hours after adding 1 cc. of barium chloride T.S.

Assay.—When dried to constant weight at 100° C. and assayed by titration with tenth-normal sodium thiosulphate, after adding potassium iodide, and diluted sulphuric acid, it shows not less than 99.9 per cent. of K_2CrO_7.

Potassium Ferricyanide, $K_3Fe(CN)_6$.—Dark red crystals. Very soluble in water. An aqueous solution (1 in 20) gives no reaction for sulphate. An aqueous solution (1 in 50), to which 2 drops of ferric chloride T.S. have been added, forms a clear, brown solution free from any green or blue coloration (*ferrocyanide*).

Potassium Ferrocyanide, $K_4Fe(CN)_6.3H_2O$.—Yellow, transparent, soft crystals very soluble in water. An aqueous solution (1 in 20) is neutral to litmus paper and gives no reaction for *sulphate.*

Potassium Hydroxide, KOH.—Use *Potassii Hydroxidum.*

Potassium Iodide, KI.—Use *Potassii Iodidum.*

Potassium Nitrate, KNO_3.—In addition to the description and tests given under *Potassii Nitras,* page 891, it should conform to the following tests: An aqueous solution (1 in 20) gives no reaction for *sulphate.* Gently ignite 1 Gm. of potassium nitrate and dissolve the residue in 10 cc. of distilled water: it gives no reaction for *chloride.*

Potassium Nitrite, KNO_2.—White or nearly white, deliquescent sticks. It responds to the identity tests for potassium and for nitrites.

Potassium Permanganate, $KMnO_4$.—Use *Potassii Permanganas.*

Potassium Sulphate, K_2SO_4.—Hard, colorless crystals or a white powder, soluble in water. An aqueous solution (1 in 20) is neutral to litmus paper, and gives no reaction for *heavy metals, chloride, iron, calcium, magnesium, ammonia,* or *nitrate.* An aqueous solution (1 in 30) meets the requirements of the test for *arsenic.*

Potassium Thiocyanate (*Potassium Sulphocyanate*), $KSCN$.—Colorless, hygroscopic crystals. Very soluble in water, completely soluble in eight parts of warm alcohol without coloration. An aqueous solution (1 in 20) gives no reaction for *sulphate, heavy metals,* or *ammonia.*

Pyrogallol, $C_6H_3(OH)_3$.—Use *Pyrogallol.*

Resorcinol, $C_6H_4(OH)_2$.—Use *Resorcinol.*

Salicylic Acid, $HC_7H_5O_3$.—Use *Acidum Salicylicum.*

Selenous Acid, H_2SeO_3.—Colorless crystals. Efflorescent in dry air and hygroscopic in moist air. Soluble in water and in alcohol.

Silver, Ag.—Silver in foil or wire containing not more than 0.025 per cent. of *foreign metals.*

Silver Nitrate, $AgNO_3$.—Use *Argenti Nitras.*

Silver Sulphate, Ag_2SO_4.—Small, white, lustrous crystals or a white powder. Slightly soluble in water and dissolved by nitric acid, or by ammonia T.S.

Preserve in amber-colored bottles.

Sodium Acetate, $NaC_2H_3O_2.3H_2O$.—Use *Sodii Acetas.*

Sodium Acetate, Anhydrous, $NaC_2H_3O_2$.—Made from sodium acetate by heating it carefully until all water of crystallization is driven off and a dry powder results. It contains not more than 3 per cent. of *water.*

Sodium Bicarbonate, $NaHCO_3$.—Use *Sodii Bicarbonas.*

Sodium Bisulphite (*Sodium Acid Sulphite*), $NaHSO_3$.—White crystals or a white granular powder, having the odor of sulphur dioxide. Freely soluble in water, slightly soluble in alcohol. An aqueous solution (1 in 50), boiled with a slight excess of hydrochloric acid to expel sulphur dioxide, gives no reaction for *heavy metals* and 0.2 Gm., oxidized with nitric acid, meets the requirements of the test for *arsenic.*

Assay.—Dissolve a weighed amount of sodium bisulphate in distilled water, add a measured excess of tenth-normal iodine, and titrate the excess of iodine with tenth-normal sodium thiosulphate. Each cc. of tenth-normal iodine corresponds to 0.005204 Gm. of $NaHSO_3$. It shows not less than 90 per cent of $NaHSO_3$. Preserve in well-filled, well-stoppered bottles, in a cool place.

Sodium Bitartrate, $NaHC_4H_4O_6.H_2O$.—White crystals or crystalline powder. Soluble in cold water. An aqueous solution (1 in 10) is clear and colorless and gives no reaction for *sulphate* or *heavy metals.* An aqueous solution (1 in 40) gives no reaction for *chloride.*

Sodium Borate, $Na_2B_4O_7.10H_2O$.—Use *Sodii Boras.*

Sodium Bromide, NaBr.—Use *Sodii Bromidum.*

Sodium Carbonate, Anhydrous, Na_2CO_3.—A white, hygroscopic powder, soluble in water. An aqueous solution (1 in 10) should be clear and colorless and gives no reaction for *sulphate, silicate, nitrate, phosphate, calcium, magnesium, iron, ammonia, heavy metals,* contains not more than 0.005 per cent. of *chloride* and meets the requirements of the test for *arsenic.* Not more than traces of potassium should be shown by the flame test, using cobalt glass. Titrate about 1.5 Gm. of anhydrous sodium carbonate, accurately weighed, with normal sulphuric acid, methyl orange T.S. being used as indicator. It shows not less than 99 per cent. of Na_2CO_3.

Sodium Carbonate, Monohydrated, $Na_2CO_3.H_2O$.—Use *Sodii Carbonas Monohydratus.*

Sodium Chloride, NaCl.—In addition to the requirements and the tests prescribed under *Sodii Chloridum,* page 995, it is required to conform to the following additional tests. An aqueous solution of sodium chloride (1 in 20) shows no turbidity or precipitation in the addition of dilute sulphuric acid (*barium*). To a solution of 3 Gm. of sodium chloride in 80 cc. of distilled water, add 1 cc. of concentrated hydrochloric acid (page 1557), heat to boiling, and add about 5 cc. of barium chloride T.S. No precipitation takes place within twenty-four hours (*sulphate*). To a solution of 3 Gm. of sodium chloride in about 10 cc. of distilled water, add 5 cc. of ammonia T.S., and 5 cc. of sodium phosphate T.S.: no precipitation takes place within twelve hours (*magnesium salts*). Dissolve 5 Gm. of the salt in 80 cc. of distilled water, heat the solution to boiling, and add 5 cc. of ammonium oxalate T.S.: no precipitate is produced within twelve hours (*calcium*); nor is this solution affected by the addition of sodium carbonate T.S.; nor is a freshly prepared solution of the same concentration affected by the addition of ammonium sulphide T.S. (*alkali earths* and *heavy metals*). To a solution of 1 Gm. of sodium chloride in 10 cc. of distilled water, add 5 cc. of sodium cobaltic nitrite T.S.: no precipitation occurs after twenty-four hours (*potassium*). The addition of Nessler's Reagent to a solution of 3 Gm. of sodium chloride produces no yellow coloration (*ammonium salts*).

Sodium Cyanide, NaCN.—White, opaque, amorphous fragments, or a white, granular powder. Very soluble in water. An aqueous solution (1 in 10) gives no reaction for *ferrocyanides* or *thiocyanates.*

Assay.—Dissolve about 0.45 Gm. of sodium cyanide accurately weighed, in 25 cc. of distilled water, add 4 cc. of ammonia T.S., 3 drops of potassium iodide T.S., and titrate with tenth-normal silver nitrite to the production of a permanent turbidity: it shows not less than 95 per cent. of NaCN. Each cc. of tenth-normal silver nitrate represents 0.009802 Gm. of NaCN.

Sodium Hydroxide, NaOH.—Use *Sodii Hydroxidum.*

Sodium Nitrite, $NaNO_2$.—Use *Sodii Nitris.*

Sodium Nitroprusside (*Sodium Nitroferricyanide*), $Na_2Fe(NO)(CN)_5.2H_2O$.—Transparent, dark-red crystals, very soluble in water. An aqueous solution (1 in 50) gives no reaction for *sulphate.*

Sodium Oxalate, $Na_2C_2O_4$.—A white, crystalline powder, slightly soluble in water. The loss on drying at 105° C. does not exceed 0.01 per cent. The residue insoluble in water does not exceed 0.01 per cent. *Sulphate,* not over 0.001 per cent. *Chloride,* not over 0.002 per cent. *Iron,* not over 0.002 per cent. *Sodium bicarbonate,* not over 0.03 per cent. *Sodium binoxalate,* not over 0.02 per cent.

Sodium Phosphate, $Na_2HPO_4.12H_2O$.—Use *Sodii Phosphas.*

Sodium Sulphide, $Na_2S.9H_2O$.—Clear, colorless, deliquescent crystals. Very soluble in water. An aqueous solution (1 in 10) is alkaline to litmus paper and has an odor of hydrogen sulphide.

Assay.—Transfer about 0.3 Gm. of sodium sulphide, accurately weighed, to a flask containing 40 cc. of tenth-normal iodine. Allow it to stand until the sulphide is completely decomposed, add 2 cc. of hydrochloric acid and titrate with tenth-normal sodium thiosulphate. It shows not less than 95 per cent. of $Na_2S.9H_2O$. Each cc. of tenth-normal iodine represents 0.01201 Gm. of $Na_2S.9H_2O$.

Sodium Sulphite, Exsiccated, Na_2SO_3.—A white powder, freely soluble in water, slightly soluble in alcohol. An aqueous solution (1 in 50), boiled with a slight excess of hydrochloric acid to expel sulphur dioxide, gives no reaction for *heavy metals.*

Assay.—Dissolve 0.5 Gm. of exsiccated sodium sulphite in sufficient freshly boiled distilled water to make 100 cc. Run this solution gradually from a burette into a mixture of 30 cc. of tenth-normal iodine and 5 cc. of hydrochloric acid, until complete decolorization results, using starch T.S. as indicator. It shows not less than 85 per cent. of Na_2SO_3. Each cc. of tenth-normal iodine represents 0.006308 Gm. of Na_2SO_3.

Sodium Tartrate, Neutral, $Na_2C_4H_4O_6.2H_2O$.—Transparent crystals, very soluble in water, insoluble in alcohol. An aqueous solution (1 in 20) gives no reaction for *ammonia, sulphate,* or *heavy metals.* An aqueous solution (1 in 40) gives no reaction for *chloride.*

Sodium Thiosulphate, $Na_2S_2O_3.5H_2O$.—Use *Sodii Thiosulphas.*

Sodium Tungstate, $Na_2WO_4.2H_2O$.—Colorless crystals or crystalline lumps, or a white, crystalline powder. An aqueous solution (1 in 40) gives no reaction for *chloride* or *sulphate.* The loss in weight after gentle ignition does not exceed 12 per cent.

Stannous Chloride, $SnCl_2.2H_2O$.—Colorless crystals, very soluble in water, the aqueous solutions requiring a slight excess of hydrochloric acid to prevent the formation of basic chloride. An aqueous solution (1 in 50) gives no reaction for *sulphate.* When tested for *arsenic* (page 1533), 0.3 Gm. of stannous chloride produces no stain. A solution of 0.2 Gm. in 1 cc. of distilled water and 0.5 cc. of hydrochloric acid does not become opalescent upon diluting with 20 cc. of distilled water (*lead*).

Starch, Potato.—The starch separated from the tubers of *Solanum tuberosum* Linné (Fam. *Solanaceæ*). A more or less finely granular powder, consisting of starch grains of characteristic shape and appearance when examined microscopically.

Sucrose, $C_{12}H_{22}O_{11}$.—Use *Sucrosum.*

Sulphanilic Acid, $C_6H_4NH_2(SO_3H)2H_2O$.—Colorless, acicular, efflorescent crystals. Slightly soluble in water. Residue upon incineration, not over 0.05 per cent. A hot, aqueous solution (1 in 25) gives no reaction for *sulphate.*

Sulphosalicylic Acid, $C_6H_3(OH)(SO_3H).COOH$.—Colorless needles, soluble in water and in alcohol. Melting point, about 120° C.

Sulphur, S.—Use *Sulphur Præcipitatum.*

Sulphuric Acid, H_2SO_4.—Use *Acidum Sulphuricum.*

Sulphuric Acid, Concentrated, H_2SO_4.—In addition to the description and tests under *Acidum Sulphuricum,* page 55, it complies with the following tests: It contains not less than 94 per cent. and not more than 97 per cent. of H_2SO_4. Residue upon ignition not to exceed 0.001 per cent. Dilute 1 volume of the acid with 4 volumes of distilled water: no stain is produced by 25 cc. of this dilute acid when subjected to the test for *arsenic.* An aqueous solution (1 in 10) gives no reaction for *nitrate* when tested with diphenylamine.

Sulphuric Acid, Diluted.—Use *Acidum Sulphuricum Dilutum.*

Sulphuric Acid, Fuming, $H_2SO_4.SO_3$.—A heavy, fuming, colorless, oily liquid. It contains at least 84.5 per cent. of total SO_3, corresponding to about 15 per cent. of free SO_3. Specific gravity about 1.870 at 25° C. Residue upon ignition, not over 0.01 per cent. An aqueous solution (1 in 10) gives no reaction for *nitrate.*

Assay.—Cautiously add about 1 cc. of fuming sulphuric acid, accurately weighed, to 100 cc. of distilled water, and titrate with normal sodium hydroxide, methyl orange T.S. being used as indicator. Each cc. of normal sodium hydroxide corresponds to 0.040035 Gm. of SO_3.

Sulphurous Acid, H_2SO_3.—An aqueous solution having the odor of sulphur dioxide. A 10 cc. portion of sulphurous acid gives no reaction when subjected to the test for *arsenic.*

Assay.—Add about 2 Gm. of sulphurous acid, accurately weighed, to 50 cc. of tenth-normal iodine and allow it to stand for five minutes. Then titrate with tenth-normal sodium thiosulphate, starch T.S. being used as indicator. Each cc. of tenth-normal iodine corresponds to 0.003203 Gm. of SO_2. It shows not less than 6 per cent. of SO_2.

Tannic Acid.—Use *Acidum Tannicum.*

Tartaric Acid, $C_2H_2(OH)_2(COOH)_2$.—Use *Acidum Tartaricum.*

Tin, Sn.—Tin, in the form of granules or irregular fragments. Digest 5 Gm. of tin with 40 cc. of nitric acid until entirely converted into the oxide, then evaporate to dryness. Stir the residue with 25 cc. of distilled water and filter. To the filtrate add 1 cc. of diluted sulphuric acid, evaporate on a water bath as completely as possible, and add 10 cc. of distilled water. No weighable residue remains undissolved (*lead*). When converted into stannous chloride by the action of hydrochloric acid, it complies with the tests under that salt.

Toluene (*Toluol*), $C_6H_5.CH_3$.—A colorless, highly refractive, inflammable liquid. Insoluble in water, miscible with alcohol, ether, chloroform, carbon disulphide, and petroleum benzin. Specific gravity, about 0.865 at 25° C. Boiling point, about 111° C.

Trinitrophenol, $C_6H_2(OH)(NO_2)_3$.—Use *Trinitrophenol.*

Turmeric.—The dried root of *Curcuma longa* Linné, Fam. *Scitaminaceæ,* reduced to a fine powder.

Xylene, C_8H_{10}.—A colorless, transparent liquid. Boiling point, 137° to 140° C. Specific gravity, about 0.85 at 25° C.

Yeast, Compressed.—The moist, living cells of *Saccharomyces cerevisiæ* Meyen (Fam. *Saccharomycetaceæ*) or of other species of *Saccharomyces,* combined with a starchy or absorbent base. White or yellowish-white, soft and easily broken masses, having a characteristic, slightly sour odor, and not more than a faintly acid reaction to litmus paper. When examined under the microscope, numerous saccharomyces, and also oidium and mycoderma cells and starch grains are visible. Compressed yeast must not be used unless fresh, and free from mildew and musty or foul odors.

Zinc, Zn.—Zinc in the form of globules, irregular fragments, granules, or a fine powder, the latter being known as zinc dust. The stain from 10 Gm. of zinc, when determined by a blank experiment as directed under the test for *arsenic,* is barely perceptible. It contains not more than 0.08 per cent. of *iron.*

Zin cOxide, ZnO.—In addition to the description and tests under *Zinci Oxidum,* page **1170,** it should contain not more than 0.003 per cent. of *chloride.*

Test Solutions

(U. S.)

Wherever convenient or possible the strength of the following test solutions has been adjusted approximately to normality basis, which signifies that 1 liter of the solution contains a quantity of the reacting substance chemically equivalent to 1 Gm. of hydrogen.

N. or **1 N.** indicates that the quantity of the substance contained in 1 liter of the test solution is approximately equivalent to 1 Gm. of hydrogen. Multiples or subdivisions of this ratio are expressed by appropriate numerals, fractions or decimals as **4 N., N/10, 0.5 N.,** etc.

Albumen Test Solution.—Carefully separate the white from the yolk of a hen's egg, strictly fresh, having a specific gravity of not less than 1.07. Shake the white thoroughly with 100 cc. of distilled water until thoroughly mixed and all but the chalaza has undergone solution; then filter. This solution must be freshly made when required.

Ammonia Test Solution.—Use *Aqua Ammoniæ.*

Ammonia Test Solution, Alcoholic.—A solution of ammonia gas in alcohol. A clear, colorless liquid having a strong odor of ammonia. Specific gravity, about 0.80 at 25° C. When assayed by the method directed under *Aqua Ammoniæ,* it shows not less than 9 per cent. and not more than 11 per cent. by weight of NH_3.

Preserve in glass-stoppered bottles in a cool place.

Ammonia Test Solution, Stronger.—Use *Aqua Ammoniæ Fortior.*

Ammonium Carbonate Test Solution.—Dissolve 20 Gm. of reagent ammonium carbonate and 20 cc. of ammonia T.S. in sufficient distilled water to make 100 cc.

Ammonium Chloride Test Solution (2 N.).—Dissolve 10.5 Gm. of reagent ammonium chloride, in sufficient distilled water to make 100 cc.

Ammonium Molybdate Test Solution.—Dissolve 6.5 Gm. of finely powdered molybdic acid in a mixture of 14 cc. of distilled water and 14.5 cc. of stronger ammonia T.S. Cool the solution and add it slowly to a well-cooled mixture of 32 cc. of nitric acid, and 40 cc. of distilled water. Allow the solution to stand for twenty-four hours and then filter through asbestos. The reagent deteriorates upon standing and it must be rejected if, upon the addition of 2 cc. of sodium phosphate T.S. to 5 cc. of the solution, an abundant yellow precipitate does not form at once or after slight warming. Preserve in the dark; if a precipitate forms, use only the clear decanted solution.

Ammonium Oxalate Test Solution (0.5 N.).—Dissolve 3.5 Gm. of ammonium oxalate in sufficient distilled water to make 100 cc.

Ammonium Polysulphide Test Solution.—A yellow liquid, made by saturating ammonium sulphide T.S. with sulphur.

Ammonium Sulphide Test Solution.—Saturate 3 volumes of ammonia T.S. with hydrogen sulphide and add to it 2 additional volumes of ammonia T.S. Residue upon ignition, not over 0.05 per cent. The solution is not rendered turbid by either magnesium sulphate T.S. (*free ammonia*) or by calcium chloride T.S. (*carbonate*). It must be rejected when it shows an abundant precipitate of sulphur. Sodium sulphide T.S. may be used when ammonium sulphide T.S. is directed.

Preserve in small, well-filled, dark amber-colored bottles, in a cool, dark place.

Aniline Sulphate Test Solution.—Dissolve 5 cc. of aniline sulphate in 51 cc. of diluted alcohol and add sufficient distilled water to make 100 cc.

Barium Chloride Test Solution (1 N.).—Dissolve 12 Gm. of barium chloride in sufficient distilled water to make 100 cc.

Barium Hydroxide Test Solution (0.5 N.).—A saturated solution (about 8 per cent.) of barium hydroxide in recently boiled distilled water. This solution must be freshly made when required for use.

Barium Nitrate Test Solution (0.5 N.).—Dissolve 6.5 Gm. of barium nitrate in sufficient distilled water to make 100 cc.

Bromine Test Solution (*Bromine Water*).—An approximately saturated aqueous solution of bromine, prepared by agitating 2 cc. of bromine with 100 cc. of cold distilled water in a glass-stoppered bottle, the stopper of which should be lubricated with petrolatum. Preserve in a cool place, protected from light.

Cadmium Chloride Test Solution (1 N.).—Dissolve 11 Gm. of cadmium chloride in sufficient distilled water to make 100 cc.

Calcium Chloride Test Solution (1 N.).—Dissolve 7.5 Gm. of calcium chloride in sufficient distilled water to make 100 cc.

Calcium Hydroxide Test Solution (0.04 N.).—Use *Liquor Calcii Hydroxidi*, page 627.

Calcium Sulphate Test Solution (0.03 N.).—A saturated solution (about 0.25 per cent.) of calcium sulphate in distilled water.

Chloral Test Solution.—Dissolve 50 Gm. of chloral hydrate in 15 cc. of distilled water and 10 cc. of glycerin.

Chlorinated Soda Test Solution.—Use *Liquor Sodæ Chlorinatæ*.

Chlorine Test Solution (*Chlorine Water*).—Place 10 Gm. of manganese dioxide in a 500 cc. flask connected by a suitable tube with a small wash bottle containing 50 cc. of distilled water, and connect this by a delivery tube leading to the bottom of a bottle having a capacity of 1000 cc. and containing 400 cc. of distilled water, which has previously been boiled and allowed to cool. Add to the dioxide in the generating flask 25 cc. of hydrochloric acid, previously diluted with 25 cc. of distilled water, stopper the generating flask, and apply a gentle heat by means of a sand bath. Conduct the generated chlorine through the water contained in the wash bottle into the bottle containing the water, which should be loosely stoppered with purified cotton and kept, during the operation, at a temperature of about 10° C. When the air has been entirely displaced by the gas, disconnect the bottle from the apparatus and, having inserted the stopper, shake the bottle, loosening the stopper from time to time, until the gas ceases to be absorbed. If necessary, reconnect the bottle with the apparatus, and continue passing the gas and agitating, until the water is saturated. Finally, pour the chlorine water into small, dark amber-colored, glass-stoppered bottles, which should be completely filled. Chlorine T.S., even when kept from light and air, is apt to deteriorate. When required of full strength, it must be freshly prepared.

Preserve in a dark, cool place.

Cobaltous Chloride Test Solution (0.16 N.).—Dissolve 2 Gm. of cobaltous chloride in 1 cc. of hydrochloric acid and sufficient distilled water to make 100 cc.

Cupric Acetate Test Solution.—Dissolve 0.1 Gm. of cupric acetate in sufficient distilled water to make 100 cc., adding a few drops of acetic acid, if necessary, to make a clear solution.

Cupric Ammonium Sulphate Test Solution.—To cupric sulphate T.S., add ammonia T.S., drop by drop, until the precipitate at first formed is nearly but not completely redissolved, then allow to settle and decant the clear solution. This solution must be freshly made when required.

Cupric Oxide, Test Solution, Ammoniated (*Schweitzer's Reagent*).—Dissolve 10 Gm. of cupric sulphate, in 100 cc. of distilled water, add just sufficient 20 per cent. sodium hydroxide solution to precipitate the copper hydroxide, collect the latter on a filter, and wash free from sulphate. Then dissolve the purified, moist precipitate in the minimum quantity of ammonia T.S. necessary for complete solution.

Cupric Sulphate Test Solution (1 N.).—Dissolve 12.5 Gm. of cupric sulphate in sufficient distilled water to make 100 cc.

Denigè's Reagent.—Use *Mercuric Sulphate T.S.*

Diphenylamine Test Solution.—Dissolve 0.5 Gm. of diphenylamine in 100 cc. of reagent sulphuric acid, diluted with 20 cc. of distilled water. The solution should be colorless.

Ferric Ammonium Sulphate Test Solution (0.5 N.).—Dissolve 8 Gm. of reagent ferric ammonium sulphate in sufficient distilled water to make 100 cc.

Ferric Chloride Test Solution (1 N.).—Dissolve 9 Gm. of ferric chloride in sufficient distilled water to make 100 cc.

Ferrous Sulphate Test Solution.—Dissolve 8 Gm. of clear crystals of ferrous sulphate in about 100 cc. of distilled water, which has been freshly boiled. This solution must be freshly prepared when required.

Ferrous Sulphate Test Solution, Acid (0.5 N.).—Dissolve 7 Gm. of ferrous sulphate in crystals in 90 cc. of distilled water, which has been freshly boiled and cooled, and then add sufficient sulphuric acid to make 100 cc. This solution must be freshly prepared when required.

Formaldehyde Test Solution.—Use *Liquor Formaldehydi.*

Fuchsin-Sulphurous Acid Test Solution.—Dissolve 0.2 Gm. of fuchsin in 120 cc. of hot distilled water, cool the solution, add a solution of 2 Gm. of anhydrous sodium sulphite in 20 cc. of distilled water, and follow by 2 cc. of concentrated hydrochloric acid. Then dilute the solution with distilled water to 200 cc. and allow to stand for one hour before use. This solution must be frequently prepared.

Gelatin Test Solution.—Dissolve 1 Gm. of gelatin in 50 cc. of distilled water, with the aid of gentle heat and filter, if necessary. Prepare freshly when required.

Gold Chloride Test Solution (0.2 N.).—Dissolve 1 Gm. of reagent gold chloride in 35 cc. of distilled water.

Hydrogen Dioxide Test Solution.—Use *Liquor Hydrogenii Dioxidi.* This reagent must contain at least 3 per cent., by weight, of H_2O_2 when used.

Hydrogen Sulphide Test Solution.—A saturated aqueous solution of hydrogen sulphide, made by passing H_2S into cold distilled water. Keep the solution in small, dark amber-colored bottles, filled nearly to the top. Do not use unless it retains a strong odor of H_2S, and, when added to an equal volume of ferric chloride T.S., it produces at once a copious precipitate of sulphur. Preserve in a cool, dark place.

Hypophosphorous Acid Test Solution.—Use *Acidum Hypophosphorosum.*

Indigo Carmine Test Solution.—Dissolve 1 Gm. of sodium indigotindisulphonate in 150 cc. of distilled water.

Iodine and Potassium Iodide Test Solution.—Dissolve 0.5 Gm. of iodine and 1.5 Gm. of potassium iodide in 25 cc. of distilled water.

Iodine Test Solution.—Use the tenth-normal iodine volumetric solution.

Iodobromide Test Solution.—(For use in determining iodine absorption value). Dissolve 13.2 Gm. of reagent iodine in 1000 cc. of glacial acetic acid, with the aid of a gentle heat if necessary. Cool the solution to 25° C. and determine the iodine content in 20 cc. by titration with tenth-normal sodium thiosulphate, then add to the remainder of the solution a quantity of bromine chemically equivalent to that of the iodine present. Preserve in glass-stoppered bottles, protected from light.

Lead Acetate Glass Wool.—Immerse glass wool in a mixture of equal parts of lead acetate T.S. and distilled water, and remove the excess of liquid by pressing it between folds of filter paper. It should be freshly prepared when required for a test.

Lead Acetate Test Paper.—Immerse strips of heavy white filter paper, 6 mm. in width and 8 cm. in length, in a mixture of equal parts of lead acetate T.S. and distilled water, drain off the excess of liquid and dry the paper on glass in an oven at 100° C., avoiding contact with metal.

Lead Acetate Test Solution (0.5 N.).—Dissolve 9.5 Gm. of clear, transparent crystals of lead acetate, in sufficient freshly boiled distilled water to make 100 cc. Preserve in well-stoppered bottles.

Lead Acetate Test Solution, Alcoholic (0.1 N.).—Dissolve 2 Gm. of clear, transparent crystals of lead acetate in sufficient alcohol to measure 100 cc.

Preserve in well-stoppered bottles.

Lead Acetate Test Solution, Basic.—Dilute 4 Gm. of solution of lead subacetate (page 648) with enough distilled water, previously boiled and cooled, to make the product weigh 100 Gm. Preserve in small, well filled, and tightly-stoppered bottles.

Locke-Ringer's Solution:

Reagent Sodium Chloride	9.000 Gm.
Reagent Potassium Chloride	0.420 Gm.
Reagent Calcium Chloride, crystals	0.240 Gm.
Reagent Magnesium Chloride	0.005 Gm.
Sodium Bicarbonate	0.500 Gm.
Dextrose	0.500 Gm.
Water, freshly distilled from a hard glass flask	
To make	1000 cc.

The solution must be made up each day. The constituents (except the dextrose) may be made up in more concentrated stock solutions and diluted as needed.

Magnesia Mixture Test Solution.—Dissolve 5.5 Gm. of magnesium chloride and 7 Gm. of reagent ammonium chloride in 65 cc. of distilled water, add 35 cc. of ammonia T.S., set the mixture aside for a few days in a well-soppered bottle, and then filter. If not perfectly clear, filter the solution before using.

Magnesium Sulphate Test Solution (1 N.).—Dissolve 12 Gm. of magnesium sulphate in sufficient distilled water to make 100 cc.

Manganese Sulphate Test Solution (1 N.).—Dissolve 11 Gm. of manganese sulphate in 50 cc. of distilled water and add sufficient sulphuric acid to make 100 cc.

Mayer's Reagent.—See *Mercuric Potassium Iodide T.S.*

Mercuric Bromide Test Paper.—Cut stiff, heavy quantitative filter paper (see *Filter Paper, Quantitative*) into strips 3 mm. in width and about 12 cm. in length. Immerse these strips for five minutes in alcoholic mercuric bromide T.S. (see below). Remove the excess of solution by pressing the strips between filter paper and then dry them quickly on glass in an oven heated to 100° C. Place at once in a glass-stoppered, wide-mouthed bottle, and protect from light.

Mercuric Bromide Test Solution, Alcoholic (0.3 N.).—Dissolve 5 Gm. of mercuric bromide in 100 cc. of alcohol, employing a gentle heat to facilitate solution.

Preserve in glass-stoppered bottles, and protect from light.

Mercuric Chloride Test Solution (0.5 N.).—Dissolve 6.5 Gm. of mercuric chloride in sufficient distilled water to make 100 cc.

Mercuric Nitrate Test Solution (4 N.).—Dissolve 40 Gm. of red mercuric oxide in a mixture of 32 cc. of nitric acid and 15 cc. of distilled water.

Preserve in glass-stoppered bottles, protected from light.

Mercuric Potassium Iodide Test Solution (*Mayer's Reagent*).—Dissolve 1.358 Gm. of mercuric chloride in 60 cc. of distilled water, and 5 Gm. of potassium iodide in 10 cc. of distilled water. Mix the two solutions and then add sufficient distilled water to make 100 cc.

Mercuric Potassium Iodide Test Solution, Alkaline (*Nessler's Reagent*).—Dissolve 10 Gm. of potassium iodide in 10 cc. of distilled water, and add gradually, in portions, a saturated aqueous solution of mercuric chloride, with constant agitation until a slight red precipitate remains undissolved. To this mixture add 30 Gm. of potassium hydroxide, and, after solution has taken place, add 1 cc. additional of the saturated aqueous solution of mercuric chloride. Dilute this solution with distilled water until it measures 200 cc. Allow the precipitate to subside and draw off the clear liquid. A 2 cc. portion of this reagent, when added to 50 cc. of distilled water containing 0.05 mgm. of ammonia, produces at once a yellowish-brown coloration.

Mercuric Sulphate Test Solution (*Denigè's Reagent*).—Mix 5 Gm. of yellow mercuric oxide with 40 cc. of distilled water and while stirring add 20 cc. of sulphuric acid, then add 40 cc. additional distilled water, and stir until completely dissolved.

Mercurous Nitrate Test Solution (0.5 N.).—Mix 20 Gm. of mercury with 10 cc. of nitric acid and 10 cc. of distilled water, in a porcelain dish and set it aside for twenty-four hours in a cool, dark place. Separate and drain the crystals of mercurous nitrate and dissolve 15 Gm. of the crystals in a mixture of 90 cc. of distilled water and 10 cc. of diluted nitric acid.

Preserve in a dark amber-colored bottle in which a small globule of mercury is placed.

Metaphenylenediamine Hydrochloride Test Solution.—Dissolve 1 Gm. of metaphenylenediamine hydrochloride in 200 cc. of distilled water: the solution is colorless. If necessary, decolorize by heating with freshly carbonized animal charcoal.

Naphthylamine Acetate Test Solution.—Dissolve 0.5 Gm. of reagent naphthylamine acetate in 100 cc. of 30 per cent. acetic acid and filter quickly through purified cotton.

Preserve in well-stoppered bottles, protected from light.

Nessler's Reagent.—Use *Mercuric Potassium Iodide T.S., Alkaline* (see above).

Oxalic Acid Test Solution (1 N.).—Dissolve 6.8 Gm. of oxalic acid in sufficient distilled water to measure 100 cc.

Palladous Chloride Test Solution.—Dissolve 0.5 Gm. of palladous chloride in sufficient distilled water to measure 10 cc.

Preserve in glass-stoppered bottles.

Phenol Disulphonic Acid Test Solution.—Dissolve 2.5 Gm. of colorless phenol in 15 cc. of reagent concentrated sulphuric acid in a flask of suitable capacity. Add 7.5 cc. of fuming sulphuric acid, stir well, and heat for two hours at 100° C. Transfer the product, while still fluid, to a glass-stoppered bottle, and, when desired for use, warm in a water bath until liquefied.

Phloroglucinol Test Solution.—Dissolve 0.5 Gm. of phloroglucinol in 25 cc. of alcohol.

Preserve in a tightly-stoppered bottle, protected from light.

Picric Acid Test Solution (*Trinitrophenol Test Solution*).—Dissolve 1 Gm. of picric acid in 100 cc. of hot distilled water. Cool the solution and filter, if necessary.

Platinic Chloride Test Solution (0.5 N.).—Dissolve 2.6 Gm. of platinic chloride in sufficient distilled water to make 20 cc.

Potassium Acetate Test Solution.—Dissolve 10 Gm. of potassium acetate in sufficient distilled water to make 100 cc.

Potassium Carbonate Test Solution (1 N.).—Dissolve 7 Gm. of reagent anhydrous potassium carbonate in sufficient distilled water to make 100 cc.

Potassium Chromate Test Solution.—Dissolve 10 Gm. of potassium chromate in sufficient distilled water to make 100 cc.

Potassium Dichromate Test Solution (1 N., based on the basicity of CrO_3.).—Dissolve 7.5 Gm. of potassium dichromate in sufficient distilled water to make 100 cc.

Potassium Ferricyanide Test Solution (1 N.).—Dissolve 1 Gm. of potassium ferricyanide in 10 cc. of distilled water. The solution must be freshly prepared when required.

Potassium Ferrocyanide Test Solution (1 N.).—Dissolve 10 Gm. of potassium ferrocyanide in sufficient distilled water to make 100 cc.

Potassium Hydroxide Test Solution (1 N.).—Dissolve 6.5 Gm. of potassium hydroxide in sufficient distilled water to make 100 cc.

Potassium Hydroxide Test Solution, Alcoholic.—Use half-normal alcoholic potassium hydroxide.

Potassium Iodide Test Solution (1 N.).—Dissolve 16.5 Gm. of potassium iodide in sufficient distilled water to make 100 cc.

Preserve in dark amber-colored, well-stoppered bottles.

Potassium Permanganate Test Solution.—Use tenth-normal potassium permanganate.

Potassium Sulphate Test Solution.—Dissolve 1 Gm. of potassium sulphate in sufficient distilled water to make 100 cc.

Potassium Thiocyanate Test Solution (*Potassium Sulphocyanate Test Solution*).—Use tenth-normal potassium thiocyanate.

Pyrogallol Test Solution, Alkaline.—Dissolve 0.5 Gm. of pyrogallol in 2 cc. of distilled water, and 12 Gm. of potassium hydroxide in 8 cc. of distilled water. The solutions should be freshly prepared and mixed immediately before using.

Resorcinol Test Solution.—Dissolve 1 Gm. of resorcinol in sufficient reagent concentrated hydrochloric acid to make 100 cc.

Silver Ammonium Nitrate Test Solution.—Dissolve 1 Gm. of silver nitrate in 20 cc. of distilled water and add ammonia T.S., drop by drop, agitating the mixture until the precipitate at first produced is almost but not entirely redissolved, and filter.

Preserve in dark amber-colored, well-stoppered bottles.

Silver Nitrate Test Solution.—Use tenth-normal silver nitrate.

Silver Sulphate Test Solution.—Mix 1 Gm. of silver sulphate with 100 cc. of distilled water in a glass-stoppered bottle and shake the mixture thoroughly. Decant the clear solution when required for use.

Sodium Acetate Test Solution (1 N.).—Dissolve 13.6 Gm. of sodium acetate in sufficient distilled water to make 100 cc.

Sodium Bisulphite Test Solution.—Dissolve 30 Gm. of sodium bisulphite in sufficient distilled water to make 100 cc. Should the solution possess a strong odor of sulphur dioxide, add sodium hydroxide T.S., drop by drop, until the odor becomes barely perceptible. The solution must be freshly prepared when required.

Sodium Bitartrate Test Solution (1 N.).—Dissolve 9 Gm. of sodium bitartrate in 100 cc. of distilled water. The solution must be freshly prepared when required.

Sodium Carbonate Test Solution (2 N.).—Dissolve 12.5 Gm. of monohydrated sodium carbonate in sufficient distilled water to make 100 cc.

Sodium Cobaltic Nitrite Test Solution.—Dissolve 4 Gm. of cobaltous chloride and 10 Gm. of sodium nitrite in about 50 cc. of distilled water, add 2 cc. of acetic acid, and dilute with sufficient distilled water to make 100 cc. This reagent must not be kept longer than three months. It may be preserved for this length of time by the occasional addition of a few drops of acetic acid.

Sodium Cyanide Test Solution (2 N.).—Dissolve 1 Gm. of sodium cyanide in sufficient distilled water to make 10 cc. The solution must be freshly prepared when required.

Sodium Hydroxide Test Solution (1 N.).—Dissolve 4.3 Gm. of sodium hydroxide in sufficient distilled water to make 100 cc.

Sodium Hydroxide Test Solution, Special.—This solution is to be prepared of the same strength as *Liquor Sodii Hydroxidi*, employing sodium hydroxide, which, in addition to the tests prescribed under *Sodii Hydroxidum*, should show not more than 0.005 per cent. of *chloride* determined by the turbidimetric test, page 1550.

Sodium Hypobromite Test Solution.—To a solution of 40 Gm. of sodium hydroxide in 150 cc. of distilled water, add 10 cc. of bromine, and, after solution has taken place, add sufficient distilled water to make 200 cc. The solution must be freshly prepared when required.

Sodium Nitroprusside Test Solution.—Dissolve 1 Gm. sodium nitroprusside in sufficient distilled water to make 20 cc. This solution must be freshly prepared when required.

Sodium Phosphate Test Solution (1 N.).—Dissolve 12 Gm. of clear crystals of sodium phosphate in sufficient distilled water to make 100 cc.

Sodium Phosphotungstate Test Solution.—To a solution of 20 Gm. of sodium tungstate in 100 cc. of distilled water, add sufficient phosphoric acid to impart a strongly acid reaction to litmus paper, and filter. When required for use, decant the clear solution from any sediment that may be present.

Preserve the solution in amber-colored, glass-stoppered bottles.

Sodium Sulphide Test Solution (1 N.).—Dissolve 12 Gm. of sodium sulphide in sufficient distilled water to make 100 cc.

NOTE: Sodium sulphide T.S. may be used in all cases when ammonium sulphide T.S. is directed. The solution must be freshly prepared when required for use.

Sodium Tartrate Test Solution (1 N.).—Dissolve 11.5 Gm. of sodium tartrate in sufficient distilled water to make 100 cc.

Sodium Thiosulphate Test Solution.—Use tenth-normal sodium thiosulphate.

Stannous Chloride Test Solution.—Dissolve 1.5 Gm. of stannous chloride in 10 cc. of distilled water containing a few drops of hydrochloric acid.

Preserve the solution in a glass-stoppered bottle in which a fragment of reagent tin has been placed. The solution must be renewed at frequent intervals.

Stannous Chloride Test Solution, Acid.—Dissolve 40 Gm. of stannous chloride in 60 cc. of reagent concentrated hydrochloric acid.

Preserve in a glass-stoppered bottle.

Starch Test Solution.—Triturate 1 Gm. of reagent starch with 10 cc. of cold distilled water, add sufficient boiling distilled water, with constant stirring, to make 200 cc., then boil the mixture until a thin, translucent fluid is obtained. The solution must be freshly prepared and filtered, if necessary.

Starch-Potassium Iodide Test Solution.—Dissolve 0.5 Gm. of potassium iodide in 100 cc. of freshly prepared starch T.S. This solution should be made not longer than twenty-four hours before use.

Sulphanilic Acid Test Solution.—Dissolve 0.8 Gm. of sulphanilic acid in 100 cc. of a 30 per cent. solution of acetic acid. Preserve in well-stoppered bottles.

Sulphuric Acid Test Solution.—Use *Acidum Sulphuricum Dilutum*, page 1559.

Tannic Acid Test Solution.—Dissolve 1 Gm. of tannic acid in 1 cc. of alcohol, and add sufficient distilled water to measure 10 cc. This solution should be freshly prepared when required for use.

Tartaric Acid Test Solution (4 N.).—Dissolve 6 Gm. of tartaric acid in sufficient distilled water to measure 20 cc. This solution should be freshly prepared.

Trinitrophenol Test Solution.—See *Picric Acid T.S.*

Turmeric Test Paper.—Impregnate sheets of white filter paper with turmeric T.S., dry, and cut into strips of a suitable size. Preserve in well-stoppered bottles.

Turmeric Test Solution.—Digest 20 Gm. of powdered turmeric with 4 successive portions of 100 cc. each of cold distilled water, decanting the clear liquid portion each time and discarding it. Then dry the residue at a temperature not over 100° C., and digest it with 100 cc. of alcohol for several days, and filter. Turmeric turns yellow with acids, and brown with alkalies. It is unsuitable for ordinary titrations, being used for special tests.

Indicators

(U. S.)

An indicator is a substance used in volumetric analysis, usually in solution, which shows by a change of color the exact point at which a reaction is complete.

Each indicator test solution used in acidimetric or alkalimetric tests must be examined for its sensitiveness. The indicator test solution, unless otherwise directed, should be so adjusted that when 0.15 cc. of the indicator is added to 25 cc. of distilled water, 0.5 cc. of hundredth-normal acid or alkali, respectively, will distinctly develop the characteristic color changes. Indicator test solutions are injured by exposure to light and should be preserved in dark amber-colored vials. Test papers should be kept in dark bottles.

[Further information on indicators is contained in the article on *Hydrogen Ion Concentration*, Part II of this volume.]

Brom Cresol Purple (*Dibromo-orthocresol-sulphonphthalein*)—$(OH.C_6H_2BrCH_3)_2CO.C_6H_4SO_2$.—Light pink to yellowish crystals (melting point from 241° to 242° C. uncorrected), soluble in alcohol, water, and in solutions of alkali hydroxides and carbonates. Alkaline solutions of brom cresol purple are colored deep purple and exhibit dichromatism, *i. e.*, predominance of red in thick layers and of blue in thin layers. The color is changed to yellow on the addition of acids.

Brom Cresol Purple Test Solution.—In an agate mortar, grind 0.1 Gm. of the dry powder with 9.5 cc. of fiftieth-normal sodium hydroxide. When solution is complete, dilute to 250 cc. with boiled-out and cooled distilled water.

This test solution should be deep orange to wine-red in color. If it is purple, the addition of not more than 0.5 cc. of fiftieth-normal acid (to the 250 cc.) should make it wine-red; and if it is yellow, the addition of not more than 0.5 cc. of fiftieth-normal alkali should produce the wine-red coloration. The pH range is from yellow, 5.2 to 6.8, purple. Preserve in glass-stoppered bottles.

Cochineal Test Solution.—Macerate 1 Gm. of unbroken cochineal (page 357) during four days with 20 cc. of alcohol and 60 cc. of distilled water, then filter. The color of this test solution is turned violet by alkalies, and yellowish-red by acids. Cochineal T.S. is used in titrating alkaloids.

Litmus.—A blue pigment prepared from various species of *Roccella* DeCandolle. In blue cubes, masses, fragments or granules, partly soluble in water and in alcohol.

Litmus Paper.—For blue litmus paper, impregnate sheets of white filter paper with litmus T.S. and dry by suspending them on clean cord in a neutral atmosphere.

For red litmus paper, add to litmus T.S. just sufficient of a highly diluted solution of hydrochloric acid to impart to it a faint red tint, impregnate, and dry sheets of filter paper as directed above. The impregnated sheets after drying may be cut into strips as desired. Litmus test papers should respond quickly to one drop of two-hundred-and-fiftieth-normal acid or alkali, respectively. Preserve in well-stoppered bottles.

Litmus Test Solution.—Exhaust 25 Gm. of powdered litmus with three successive portions of 100 cc. each of boiling alcohol, continuing each extraction for about one hour. Filter, wash with alcohol, and discard the alcoholic filtrate. Digest the residue with about 25 cc. of cold distilled water and filter. Discard this filtrate also. Finally extract the residue with 125 cc. of boiling distilled water and, after thoroughly cooling, filter. Litmus turns red with acids and blue with alkalies. The pH range is from red, 4.5 to 8.3, blue. Litmus is unsuitable for determining alkaloids, carbonates, or bicarbonates. Preserve the filtrate in wide-mouthed bottles, stoppered with loose plugs of purified cotton.

Methyl Orange (*Tropæolin D., Dimethylaniline Orange*).—The sodium salt of paradimethylaminoazobenzene sulphonic acid, $(CH_3)_2\text{–}N\text{–}C_6H_4\text{–}N=N\text{–}C_6H_4.SO_3Na$. An orange-yellow powder, slightly soluble in cold water, insoluble in alcohol.

Methyl Orange Test Solution.—Dissolve 0.1 Gm. of methyl orange in 100 cc. of distilled water. Methyl orange turns from orange to rose-red with acids, and to yellow with alkalies. This indicator is not suitable for determining organic acids or alkaloids, nor should it be used in alcoholic or in very hot solutions. The pH range is from orange red, 3.1 to 4.4, yellow.

Methyl Red (*Paradimethylaminoazobenzeneorthocarboxylic Acid*) $(CH_3)_2\text{–}N\text{–}C_6H_4\text{–}N=N\text{–}C_6H_4.COOH$.—Violet crystals sparingly soluble in cold water, soluble in alcohol.

Methyl Red Test Solution.—Dissolve 0.2 Gm. of methyl red in 100 cc. of alcohol. Methyl red turns from red with acids to yellow with alkalies. This solution is unsatisfactory for the determination of carbonates or bicarbonates. It is very satisfactory for many alkaloids. The pH range is from red, 4.2 to 6.3, yellow.

Phenol Red (*Phenolsulphonphthalein*).—Use *Phenolsulphonphthaleinum*, page 834.

Phenol Red Test Solution.—In an agate mortar, grind 0.1 Gm. of the dry powder with 14.5 cc. of fiftieth-normal sodium hydroxide. When solution is complete, dilute to 250 cc. with boiled-out and cooled distilled water. Filter off the insoluble residue. The zone of color transformation of this indicator is from yellow, pH 6.8 to 8.4, red. Preserve in a glass-stoppered bottle.

Phenolphthalein.—Use *Phenolphthaleinum*, page 833.

Phenolphthalein Test Solution.—Dissolve 1 Gm. of phenolphthalein in 100 cc. of alcohol. Phenolphthalein is colorless with acids and turns red with alkalies. This test solution is not satisfactory for determining alkaloids, ammonia, carbonates, or bicarbonates in cold solutions. The pH range is from colorless, 8.3 to 10.0, red.

Phenolphthalein Test Paper.—Impregnate sheets of white unsized paper with phenolphthalein T.S., dry, and cut into strips of a suitable size. Preserve as directed under litmus paper.

Volumetric Solutions

(U. S.)

It is absolutely necessary that the measuring vessels employed in the operations of volumetric analysis (burettes, flasks, mixing cylinders, pipettes, etc.) shall agree accurately among themselves in their graduation at the standard temperature selected. All volumetric solutions, if practicable, should be prepared at the standard temperature of 25° C. and used in titrations at that standard temperature. If a titration is made at a markedly different temperature, a volumetric solution should be used which has been standardized for such temperature. In case graduated apparatus calibrated at 25° C. is not procurable, volumetric solutions may be prepared at the temperature for which the apparatus in hand was graduated (*e.g.*, 15° C. or 20° C.), and all such volumetric solutions should be marked to indicate the temperature at which they have been standardized. Such solutions must be used as above stated at the temperature at which the apparatus is standardized, care being taken that all graduated apparatus used be standardized at the same temperature.

Units of Capacity.—The units of volume employed by this Pharmacopœia must accord with its standard liter at 25° C., which represents the volume occupied by 996.04 Gm. of distilled water, weighed in air with brass weights, at a temperature of 25° C.[1] and barometer at 760 mm. To secure uniformity among the various forms of apparatus employed, the standard specifications of the U. S. Bureau of Standards should be adhered to as closely as possible, except that the temperature adopted is 25° C. The tables for calibrating graduated apparatus will be found on page 1632.

Measuring Flasks.—Standard measuring flasks are calibrated to contain, when filled to the mark, 1000, 500, 250, 200, or 100 cc., at 25° C. The necks must be of uniform caliber, and measure in diameter not less than 14 mm. and not more than 20 mm. for 1000 cc. capacity; from 12 mm. to 18 mm. for 500 cc. capacity; from 10 mm. to 15 mm. for 250 cc. capacity, and from 8 mm. to 12 mm. for 100 cc. capacity. The capacity mark on any of these flasks should be not less than 6 cm. distant from the mouth and not less than 2 cm. from the base of the neck.

Cylinders.—These should be graduated to contain their respective volumes at the standard temperature. Their inside diameter must not be more than one-fifth the graduated length.

Transfer Pipettes.—These should be graduated to deliver at standard temperature the exact volume of fluid indicated. The suction stem should be at least 16 cm. long, and the delivery tube not less than 3 cm. and not more than 25 cm. long. The inside diameter at the capacity mark must not be less than 2 mm. and must not exceed 4 mm. for those of 25 cc. capacity. The capacity mark should not be more than 6 cm. from the bulb. The outlet of any transfer pipette should be of such size that the free outflow for water shall last not more than one minute, and not less than fifteen seconds for 5 cc., twenty seconds for 10 cc., and thirty seconds for 50 cc. After filling, the fluid adhering to the outside should be wiped from the stem; then when draining the contents, the pipette should be held in a vertical position; finally, to complete the emptying, the tip of the pipette should be held against the side of the vessel, permitting the last portions of the fluid to flow out by gravity. Pipettes should never be drained by blowing into them, except the Oswald pipettes which are especially graduated for use in this way.

Burettes.—These must be provided with glass stop-cocks and be graduated for use at the standard temperature. Burettes provided with rubber tubes and pinch-cocks in place of glass stop-cocks may be used for potassium and sodium hydroxide V.S. The tips should be gradually tapered from 2 to 3 cm. in length and slightly bent. The rate of outflow should be regulated so that not less than 2 seconds should be consumed for each cc. delivered. When completing titration, the tip of the delivery tube should be touched with the wet surface of the receiving vessel to complete the emptying.

GENERAL DIRECTIONS.—All bottles in which volumetric solutions are to be kept, as well as the burettes or pipettes in which they are to be measured, should be thoroughly cleaned prior to use, and rinsed first with distilled water, and then with two or three small portions of the solution that they are to contain. In all apparatus where the surface of the fluid is limited by a meniscus, the reading must be made from the lowest point of the meniscus unless the liquid is too opaque to permit exact observation of that point. It is of the utmost importance that the inner surface of all measuring apparatus shall be free from any suggestion of greasiness.

Normal Volumetric Solutions $\left(\frac{N}{1}\right)$ are those which contain in 1000 cc., in any stated reaction, the chemical equivalent of 1.008 Gm. of hydrogen. If the molecule of the reagent is univalent, one liter will contain a weight in grammes equal to the molecular weight of the reagent; if bivalent, a weight in grammes equal to one-half its molecular weight; if trivalent, a weight in grammes equal to one-third its molecular weight. Thus, hydrochloric acid, $HCl = 36.47$, having but one H atom replaceable by a basic element, has 36.47 Gm. of HCl in 1000 cc. of the normal volumetric solution; while sulphuric acid, $H_2SO_4 = 98.09$, having two replaceable H atoms, contains only one-half this number, or 49.045 Gm. of H_2SO_4 in 1000 cc. of its normal solution. Potassium hydroxide, $KOH = 56.11$, has but one K to replace one H in acids, hence its normal solution contains 56.11 Gm. of KOH in one liter. Again, one molecule of potassium dichromate ($K_2Cr_2O_7 = 294.20$) in oxidation liberates three atoms of oxygen which are capable of combining with six atoms of hydrogen. Therefore, each molecule of the dichromate, yielding three atoms of oxygen, is equivalent to six atoms of hydrogen. Hence, the normal solution should contain $\frac{294.20}{6}$ or 49.0333 Gm. in 1000 cc. Two molecules of potassium permanganate, $2KMnO_4 = 316.06$, in oxidation, give off five atoms of O, which are equivalent to ten atoms of H; hence its normal solution should contain $\frac{316.06}{10}$ or 31.606 in 1000 cc. Solutions containing in 1000 cc. one-tenth of the quantity of the active reagent in the normal solution are called tenth-normal (decinormal) $\left(\frac{N}{10}\right)$ (normality = 0.1); those containing one one-hundredth, hundredth-normal (centinormal) $\left(\frac{N}{100}\right)$ (normality = 0.01); those containing one-fiftieth, fiftieth-normal $\left(\frac{N}{50}\right)$ (normality = 0.02); those containing twice the amount, double-normal $\left(\frac{2N}{1}\right)$ (normality = 2); half the amount, half-normal $\left(\frac{N}{2}\right)$ (normality = 0.5). Solutions containing quantities of the active reagent having no simple relation to the molecular weight are called empirical. The general policy has been followed to limit the factors of volumetric solutions to four significant figures.

Use of Empirical Solutions.—As it is difficult to maintain the theoretical standard strength with many volumetric solutions, it is not absolutely necessary that such standard strength be maintained, or even attained originally. A solution of approximately the desired normality is prepared and its strength accurately determined. The correction factor of the normality is applied in all calculations where the empirical solution is employed. As many volumetric solutions are subject to alteration in strength on keeping, their strength should frequently be ascertained.

When the same kind of volumetric solution of several normalities is used, the details of the preparation and standardization are given for the strength most frequently required. Stronger or weaker solutions are prepared and standardized in the same manner as the solutions described, using proportionate amounts of material. Whenever convenient, it is preferable to prepare tenth or lower normality solutions by properly diluting the stronger volumetric solutions, but in preparing any alkali hydroxide volumetric solution by dilution, its exact strength must be ascertained by the same method of titration as described under the stronger solution.

---

[1] 500 cc. would weigh 498.02 Gm.; 250 cc., 249.01 Gm.; 100 cc., 99.604 Gm.

Alkaline Cupric Tartrate Volumetric Solution

FEHLING'S SOLUTION

A. The Copper Solution.—Dissolve 34.66 Gm. of carefully selected, small crystals of cupric sulphate, showing no trace of efflorescence or of adhering moisture, in a sufficient quantity of distilled water to make the solution measure exactly 500 cc. at standard temperature. Keep this solution in small, well-stoppered bottles.

B. The Alkaline Tartrate Solution.—Dissolve 173 Gm. of crystallized potassium and sodium tartrate and 50 Gm. of sodium hydroxide in a sufficient quantity of distilled water to make the solution measure exactly 500 cc. at standard temperature. Keep the solution in small, rubber-stoppered bottles.

For use, mix exactly equal volumes of the two solutions at the time required.

NOTE: In this Pharmacopœia Fehling's Solution is not used as a volumetric reagent, but is used qualitatively. The correct formula is given for the volumetric solution, because of its extensive use in this manner. It must always be used under carefully standardized conditions in quantitative work, and in connection with tables which will be found in "Official and Tentative Methods of Analysis of the Association of Official Agricultural Chemists."

Barium Hydroxide, Tenth-Normal

$Ba(OH)_2.8H_2O = 315.51$ 15.776 Gm. in 1000 cc.

Dissolve about 18 Gm. of reagent barium hydroxide in 1000 cc. of recently boiled and cooled distilled water, and, if necessary, filter the solution quickly.

Ascertain the exact strength by titration against tenth-normal hydrochloric acid, phenolphthalein T.S. being used as indicator, and adjust to exact normality or to a known strength of approximate normality. This solution deteriorates rapidly and should be standardized before using.

Preserve the solution in rubber-stoppered bottles provided with soda-lime tube as directed under normal sodium hydroxide.

One cubic centimeter of Tenth-Normal Barium Hydroxide is the equivalent of:

	Gramme
Barium Hydroxide, $Ba(OH)_2.8H_2O$	0.01578
Ammonium Benzoate, $NH_4C_7H_5O_2$	0.01391
Ammonium Salicylate, $NH_4C_7H_5O_3$	0.01551
Benzoic Acid, $HC_7H_5O_2$	0.01221
Hydrochloric Acid, HCl	0.03647
Salicylic Acid, $HC_7H_5O_3$	0.01381
Sodium Benzoate, $NaC_7H_5O_2$	0.01441
Sulphuric Acid, H_2SO_4	0.004904

Bromine, Tenth-Normal

KOPPESCHAAR'S SOLUTION

Br = 79.92 7.992 Gm. in 1000 cc.

Dissolve 3 Gm. of potassium bromate and 50 Gm. of potassium bromide in sufficient distilled water to make 1000 cc.

Ascertain its exact strength by titration against tenth-normal sodium thiosulphate after the addition of potassium iodide and a slight excess of hydrochloric acid, and adjust to exact normality or to a known strength of approximate normality. Preserve in dark amber-colored, glass-stoppered bottles.

One cubic centimeter of Tenth-Normal Bromine is the equivalent of:

	Gramme
Bromine, Br	0.007992
Phenol, C_6H_5OH	0.001568
Resorcinol, $C_6H_4(OH)_2$	0.001835
Sodium Phenolsulphonate, anhydrous, $NaC_6H_5O_4S$	0.004903
Sodium Phenolsulphonate, crystallized, $NaC_6H_5O_4S.2H_2O$	0.005804

Hydrochloric Acid, Normal

HCl = 36.47 36.47 Gm. in 1000 cc.

Mix 95 cc. of hydrochloric acid with sufficient distilled water to measure 1000 cc.

Ascertain its exact strength by titration against freshly standardized sodium carbonate or normal sodium hydroxide, methyl orange T.S. being used as indicator; or gravimetrically by precipitation as silver chloride, and adjust to exact normality or to a known strength of approximate normality.

One cubic centimeter of Normal Hydrochloric Acid is the equivalent of:

	Gramme
Hydrochloric Acid, HCl	0.03647
Barium Hydroxide, $Ba(OH)_2.8H_2O$	0.1578
Calcium Carbonate, $CaCO_3$	0.05004
Calcium Hydroxide, $Ca(OH)_2$	0.03705

	Gramme
Calcium Oxide, CaO	0.02804
Potassium Hydroxide, KOH	0.05611
Sodium Borate, anhydrous, $Na_2B_4O_7$	0.1008
Sodium Borate, crystallized, $Na_2B_4O_7.10H_2O$	0.1909
Sodium Cacodylate, anhydrous, $Na(CH_3)_2.AsO_2$	0.16002
Sodium Hydroxide, $NaOH$	0.04001

NOTE: Normal hydrochloric acid is in every aspect equivalent in neutralizing power to normal sulphuric acid and may be employed, except in special cases, for the same purposes.

Hydrochloric Acid, Half-Normal

$HCl = 36.47$ 18.235 Gm. in 1000 cc.

One cubic centimeter of Half-Normal Hydrochloric Acid is the equivalent of:

	Gramme
Hydrochloric Acid, HCl	0.01824

Other factors are identical with those under Half-Normal Sulphuric Acid.

Hydrochloric Acid, Fiftieth-Normal

$HCl = 36.47$ 0.7294 Gm. in 1000 cc.

One cubic centimeter of Fiftieth-Normal Hydrochloric Acid is the equivalent of:

	Gramme
Hydrochloric Acid, HCl	0.0007294

This volumetric solution is not used officially for titration but is employed in connection with the special Turbidimetric Test.

Iodine, Tenth-Normal

$I = 126.92$ 12.692 Gm. in 1000 cc.

METHOD I.—Dissolve 12.692 Gm. of reagent iodine in a solution of 18 Gm. of potassium iodide in 100 cc. of distilled water. Then add sufficient distilled water to make the solution measure exactly 1000 cc. at 25° C. Unless freshly prepared its normality should always be redetermined before use. Preserve in glass-stoppered bottles.

METHOD II.—Tenth-normal iodine may also be prepared as follows:

Dissolve about 14 Gm. of reagent iodine in a solution of 18 Gm. of potassium iodide in about 100 cc. of distilled water, diluting finally to 1000 cc. Carefully measure from a burette 25 cc. of this solution (which is too concentrated), into a flask, then add gradually and cautiously from a burette tenth-normal sodium thiosulphate, shaking constantly, until the color of the solution is but slightly yellow, then add a few drops of starch T.S. and continue the addition of the tenth-normal sodium thiosulphate until the blue color is just discharged. Note the number of cc. of the tenth-normal sodium thiosulphate consumed and then dilute the iodine solution so that 25 cc. will require for decolorization exactly 25 cc. of the tenth-normal sodium thiosulphate at standard temperature.

One cubic centimeter of Tenth-Normal Iodine is the equivalent of:

	Gramme
Iodine, I	0.01269
Acetone, $(CH_3)_2CO$	0.0009677
Antimony and Potassium Tartrate, crystallized, $K(SbO)C_4H_4O_6.\frac{1}{2}H_2O$	0.01662
Arsenic, in arsenous compounds, As	0.003748
Arsenous Iodide, AsI_3	0.02279
Arsenic Trioxide (Arsenous Acid), As_2O_3	0.004948
Calcium Sulphide, CaS	0.003607
Iron, Fe	0.002792
Mercurous Chloride, $HgCl$	0.02361
Mercurous Iodide, HgI	0.03275
Mercury (in mercurous compounds), Hg	0.02006
Sodium Bisulphite, $NaHSO_3$	0.005204
Sodium Sulphite, anhydrous, Na_2SO_3	0.006303
Sodium Thiosulphate, anhydrous, $Na_2S_2O_3$	0.01581
Sodium Thiosulphite, crystallized, $Na_2S_2O_3.5H_2O$	0.02482
Sulphur Dioxide, SO_2	0.003203

Oxalic Acid, Tenth-Normal

$H_2C_2O_4.2H_2O = 126.06$ 6.303 Gm. in 1000 cc.

Dissolve 6.45 Gm. of reagent oxalic acid in sufficient distilled water to measure 1000 cc. Ascertain its exact strength by titration against freshly standardized tenth-normal sodium hydroxide, phenolphthalein T.S. being used as indicator, and adjust to exact normality or to a known strength of approximate normality.

One cubic centimeter of Tenth-Normal Oxalic Acid is the equivalent of:

	Gramme
Oxalic Acid, crystallized, $H_2C_2O_4.2H_2O$	0.006303
Ammonia Gas, NH_3	0.001703
Calcium Carbonate, $CaCO_3$	0.005004

	Gramme

Calcium Oxide, CaO	0.002804
Lead, Pb	0.01036
Lead Acetate, anhydrous, $Pb(C_2H_3O_2)_2$	0.01626
Lead Acetate, crystallized, $Pb(C_2H_3O_2)_2.3H_2O$	0.01897
Lead Oxide, PbO	0.01116
Lead Peroxide, PbO_2	0.01196
Lead Subacetate, approximately, $Pb_2O(C_2H_3O_2)_2$	0.01371
Manganese Dioxide, MnO_2	0.004347
Potassium Hydroxide, KOH	0.005611
Potassium Permanganate, $KMnO_4$	0.003161
Sodium Hydroxide, $NaOH$	0.004001

Potassium Dichromate, Tenth-Normal

$K_2Cr_2O_7 = 294.20$ 4.9033 Gm. in 1000 cc.

Method I.—Dissolve 4.9033 Gm. of potassium dichromate, which has been pulverized and dried to constant weight at 120° C., in sufficient distilled water to measure exactly 1000 cc. at standard temperature.

Method II.—Tenth-normal potassium dichromate may also be prepared as follows:

Dissolve about 5 Gm. of potassium dichromate in 1000 cc. of distilled water, transfer exactly 25 cc. of this solution to a 500 cc. glass-stoppered flask, add 2 Gm. of potassium iodide (free from iodate), dilute with 200 cc. of distilled water, add 5 cc. of hydrochloric acid, allow to stand for ten minutes in a dark place, and titrate the liberated iodine with tenth-normal sodium thiosulphate, using starch T.S. at the end of the titration as indicator. Adjust to exact normality or to a known strength of approximate normality.

For estimating ferrous iron, it is used in the following manner. Introduce an acidulated aqueous solution of the ferrous compound into a flask. Gradually add the tenth-normal potassium dichromate from a burette with agitation until a drop placed upon a white porcelain surface no longer becomes blue when mixed with a drop of freshly prepared potassium ferricyanide T.S. Several closely agreeing determinations should be made before finally calculating the result.

One cubic centimeter of Tenth-Normal Potassium Dichromate is the equivalent of:

	Gramme
Potassium Dichromate, $K_2Cr_2O_7$	0.004903
Ferrous Carbonate, $FeCO_3$	0.01159
Ferrous Sulphate, anhydrous, $FeSO_4$	0.01519
Ferrous Sulphate, crystallized, $FeSO_4.7H_2O$	0.02780
Iron, in ferrous compounds, Fe	0.005584
Sodium Thiosulphate, $Na_2S_2O_3.5H_2O$	0.02482

Potassium Hydroxide, Dekanormal

$KOH = 56.11$ 561.1 Gm. in 1000 cc.

Prepare and preserve as directed under normal potassium hydroxide.

Note: This solution is intended specifically for the ready measurement of definite amounts of absolute potassium hydroxide, hence it is not necessary to adjust the solution to exact strength, but the factor of strength must be accurately known and the solution used accordingly. The use of barium hydroxide in this solution is unnecessary, provided the solution be allowed to settle before standardizing and only the clear liquid employed.

Potassium Hydroxide, Normal

$KOH = 56.11$ 56.11 Gm. in 1000 cc.

Normal Potassium Hydroxide is used only as an alternative solution. It is prepared and standardized in exactly the same manner as normal sodium hydroxide, using an equivalent quantity of the base for preparing the solution.

The factors for this solution are the same as for normal sodium hydroxide which is preferred on account of its economy.

Potassium Hydroxide Alcoholic, Half-Normal

$KOH = 56.11$ 28.055 Gm. in 1000 cc.

Dissolve 2.5 Gm. of silver nitrate in 5 cc. of distilled water and add the solution to 1200 cc. of alcohol in a glass-stoppered bottle, and mix thoroughly. Dissolve 5 Gm. of potassium hydroxide in 25 cc. of warm alcohol, cool the solution, and pour it slowly, without stirring, into the alcoholic solution of silver nitrate. Let the mixture stand until the precipitated silver oxide has settled, filter, and distil. Dissolve about 35 Gm. of potassium hydroxide in 20 cc. of distilled water and add sufficient alcohol, purified as above, to make 1000 cc. Allow the solution to stand in a tightly stoppered bottle (using either a glass or rubber stopper) for twenty-four hours, then quickly decant the clear supernatant liquid into a bottle provided with a well-fitting rubber stopper. Ascertain the strength by titration against a hot solution of reagent potassium bitartrate, phenolphthalein T.S. being used as indicator, and adjust to exact normality or to a known strength of approximate normality. The strength may also be ascertained and adjusted after titration against half-normal hydrochloric acid.

Note: This solution should be kept in bottles provided with well-fitting stoppers of rubber, or of cork which have been well coated with paraffin, and it should be protected from light. It should be restandardized whenever it is used. It is very important that this solution should be used at the same temperature at which it was standardized.

One cubic centimeter of Half-Normal Alcoholic Potassium Hydroxide is the equivalent of:

	Gramme
Potassium Hydroxide, KOH	0.02806
Borneol, $C_{10}H_{17}OH$	0.07710
Bornyl Acetate, $C_{10}H_{17}.C_2H_3O_2$	0.09811
Linalyl Acetate, $C_{10}H_{17}.C_2H_3O_2$	0.09811
Menthol, $C_{10}H_{19}OH$	0.07811
Menthyl Acetate, $C_{10}H_{19}.C_2H_3O_2$	0.09912
Menthyl Salicylate, $CH_3.C_7H_5O_3$	0.07605
Potassium Bitartrate, $KHC_4H_4O_6$	0.09408
Santalol, $C_{15}H_{24}O$	0.1101

Potassium Permanganate, Tenth-Normal

$KMnO_4 = 158.03$ 3.1606 Gm. in 1000 cc.

Dissolve about 3.3 Gm. of potassium permanganate in 1000 cc. of distilled water in a flask and boil for about five minutes. Close the flask with absorbent cotton and allow it to stand for at least two days, then pour off the clear portion of the solution or filter through asbestos. The water for preparing and diluting this solution should be freshly distilled after adding about 1 Gm. of potassium permanganate to each liter of water in the retort before beginning the distillation. Ascertain its exact strength by titration against reagent sodium oxalate, and adjust to exact normality or to a known strength of approximate normality.

The strength may also be determined and adjusted by titrating against tenth-normal sodium thiosulphate after the addition of diluted sulphuric acid and an excess of potassium iodide.

Burettes provided with glass stop-cocks must be employed when titrating with this solution. It should be frequently restandardized. Preserve in glass-stoppered bottles.

One cubic centimeter of Tenth-Normal Potassium Permanganate is the equivalent of:

	Gramme
Potassium Permanganate, $KMnO_4$	0.003161
Calcium Oxide, CaO (as oxalate)	0.002804
Ferrous Carbonate, $FeCO_3$	0.01159

Ferrous Sulphate, anhydrous, $FeSO_4$	0.01519
Ferrous Sulphate, crystals, $FeSO_4.7H_2O$	0.02780
Hydrogen Dioxide, H_2O_2	0.001701
Iron, in ferrous compounds, Fe	0.005584
Oxalic Acid, crystallized, $H_2C_2O_4.2H_2O$	0.006303
Oxygen, O	0.0008
Potassium Chlorate, $KClO_3$	0.002043
Sodium Chlorate, $NaClO_3$	0.001774
Sodium Nitrate, $NaNO_2$	0.003451
Sodium Oxalate, $Na_2C_2O_4$	0.006701

Potassium Thiocyanate, Tenth-Normal

$KSCN = 97.173$ 9.7173 Gm. in 1000 cc.

Dissolve 11 Gm. of reagent potassium thiocyanate in 1000 cc. of distilled water. Ascertain its exact strength by titration against tenth-normal silver nitrate, and adjust to exact normality or to a known strength of approximate normality.

One cubic centimeter of Tenth-Normal Potassium Thiocyanate is the equivalent of:

	Gramme
Potassium Thiocyanate, $KSCN$	0.009717
Mercuric Iodide, HgI_2	0.02272
Mercuric Nitrate, $Hg(NO_3)_2$	0.01623
Mercuric Oxide, HgO	0.01083
Mercury, Hg	0.01003
Silver, Ag	0.01079
Silver Nitrate, $AgNO_3$	0.01699
Silver Oxide, Ag_2O	0.01159

Silver Nitrate, Tenth-Normal

$AgNO_3 = 169.89$ 16.989 Gm. in 1000 cc.

METHOD I.—In a flask containing 10.788 Gm. of silver and provided with a small funnel inserted into the neck to prevent loss by spurting, introduce gradually about 30 cc. of nitric acid, or sufficient for complete solution. After thoroughly rinsing the funnel, transfer the clear solution, with the rinsings, to a beaker or porcelain dish, and evaporate to dryness on a water bath, carefully protecting the vessel from dust. Then dry in an oven at about 120° C. for ten minutes, cool the residue, and dissolve it in 1000 cc. of distilled water at 25° C.

METHOD II.—The solution may also be made by dissolving 17.006 Gm. of thoroughly dried silver nitrate in enough distilled water to make 1000 cc.

One cubic centimeter of Tenth-Normal Silver Nitrate is the equivalent of:

Sodium Hydroxide, Dekanormal

NaOH = 40.01 400.1 Gm. in 1000 cc.

Prepare and preserve as directed under normal sodium hydroxide.

NOTE: This solution is intended specifically for the ready measurement of definite amounts of absolute sodium hydroxide, hence it is not necessary to adjust the solution to exact strength, but the factor of strength must be accurately known and the solution used accordingly. The use of barium hydroxide in this solution is unnecessary, provided the solution be allowed to settle before standardizing and only the clear liquid employed.

Sodium Hydroxide, Double-Normal

NaOH = 40.01 80.02 Gm. in 1000 cc.

Preserve the solution as directed under normal sodium hydroxide (see below). This solution should be frequently restandardized.

Sodium Hydroxide, Normal

NaOH = 40.01 40.01 Gm. in 1000 cc.

Dissolve 45 Gm. of sodium hydroxide in about 950 cc. of distilled water and add a freshly prepared saturated solution of reagent barium hydroxide until no more precipitate forms. Allow the precipitate to subside, decant the clear liquid or filter the solution, and determine its strength by titration against a hot solution of an accurately weighed quantity of reagent potassium bitartrate, or against normal hydrochloric or sulphuric acid, and adjust to exact normality or to a known strength of approximate normality.

NOTE: Solutions of alkali hydroxides absorb carbon dioxide when exposed to the atmosphere. They should therefore be preserved in bottles with well-fitting rubber stoppers, provided with tubes filled with a mixture of sodium hydroxide and lime (soda-lime tubes) so that air in entering the container must pass through such tubes which will absorb the carbon dioxide.

The solution should be frequently restandardized.

One cubic centimeter of Normal Sodium Hydroxide is the equivalent of:

	Gramme
Sodium Hydroxide, $NaOH$	0.04001
Acetic Acid, $HC_2H_3O_2$	0.06004
Acetic Anhydride, $(CH_3CO)_2O$	0.05104
Ammonia Gas, NH_3	0.01703
Boric Acid, H_3BO_3	0.06192
Chloral Hydrate, $CCl_3CHO.H_2O$	0.1654
Citric Acid, crystallized, $H_3C_6H_5O_7.H_2O$	0.07004
Formaldehyde, $HCHO$	0.03002
Hydriodic Acid, HI	0.1279
Hydrobromic Acid, HBr	0.08093
Hydrochloric Acid, HCl	0.03647
Hypophosphorous Acid, HPH_2O_2	0.06606
Lactic Acid, $HC_3H_5O_3$	0.09006
Nitric Acid, HNO_3	0.06302
Oxalic Acid, crystallized, $H_2C_2O_4.2H_2O$	0.06303
Paraformaldehyde, $(HCHO)_3$	0.03002
Phosphoric Acid, H_3PO_4 (to form Na_2HPO_4; with phenolphthalein)	0.04903
Potassium Bitartrate, $KHC_4H_4O_6$	0.1882
Potassium Hydroxide, KOH	0.05611
Sodium Bisulphate, $NaH_2PO_4.H_2O$	0.1381
Sodium Biphosphate, anhydrous, NaH_2PO_4	0.1201
Sodium Bitartrate, $NaHC_4H_4O_6.H_2O$	0.1901
Sulphuric Acid, H_2SO_4	0.04904
Sulphuric Anhydride, SO_3	0.04003
Tartaric Acid, $H_2C_4H_4O_6$	0.07504
Trichloracetic Acid, $CCl_3.COOH$	0.1634

Sodium Hydroxide, Half-Normal

$NaOH = 40.01$ 20.005 Gm. in 1000 cc.

Preserve as directed under normal sodium hydroxide. This solution should be frequently restandardized.

One cubic centimeter of Half-Normal Sodium Hydroxide is the equivalent of:

	Gramme
Sodium Hydroxide, $NaOH$	0.02001
Acetic Acid, $HC_2H_3O_2$	0.03002
Acetylsalicylic Acid, $C_6H_4.O(C_2H_3O).COOH$	0.04503
Benzyl Benzoate, $C_6H_5CO_2.CH_2C_6H_5$	0.1061
Boric Acid, H_3BO_3	0.03100
Citric Acid, crystallized, $H_3C_6H_5O_7.H_2O$	0.03502
Hydriodic Acid, HI	0.06397
Hydrobromic Acid, HBr	0.04047
Hydrochloric Acid, HCl	0.01824
Hypophosphorous Acid, HPH_2O_2	0.03303
Lactic Acid, $HC_3H_5O_3$	0.04503
Nitric Acid, HNO_3	0.03151
Oxalic Acid, crystallized, $H_2C_2O_4.2H_2O$	0.03152
Phosphoric Acid, H_3PO_4 (to form Na_2HPO_4; with phenolphthalein)	0.02452
Potassium Bitartrate, $KHC_4H_4O_6$	0.09408
Potassium Hydroxide, KOH	0.02806
Sodium Bitartrate, $NaHC_4H_4O_6.H_2O$	0.09504
Sulphuric Acid, H_2SO_4	0.02452
Sulphuric Anhydride, SO_3	0.02002
Tartaric Acid, crystallized, $H_2C_4H_4O_6$	0.03752
Trichloracetic Acid, $CCl_3.COOH$	0.08170

Sodium Hydroxide, Tenth-Normal

$NaOH = 40.01$ 4.001 Gm. in 1000 cc.

Preserve as directed under normal sodium hydroxide. This solution should be frequently restandardized.

One cubic centimeter of Tenth-Normal Sodium Hydroxide is the equivalent of:

	Gramme
Sodium Hydroxide, $NaOH$	0.004001
Cinchophen, $C_6H_5.C_9H_5N.COOH$	0.02492
Eucaine Hydrochloride, $C_{15}H_{21}O_2N.HCl$	0.02837
Lactic Acid, $HC_3H_5O_3$	0.009006
Potassium Bitartrate, $KHC_4H_4O_6$	0.01882
Potassium Hydroxide, KOH	0.005611
Sulphuric Acid, H_2SO_4	0.004904

Sodium Hydroxide, Fiftieth-Normal

$NaOH = 40.01$ 0.800 Gm. in 1000 cc.

Preserve as directed under normal sodium hydroxide. This solution should be frequently restandardized.

One cubic centimeter of Fiftieth-Normal Sodium Hydroxide is the equivalent of:

	Gramme
Sodium Hydroxide, $NaOH$	0.0008002
Potassium Bitartrate, $KHC_4H_4O_6$	0.003763
Sulphuric Acid, H_2SO_4	0.0009808

Sodium Hydroxide, Hundredth-Normal

$NaOH = 40.01$ 0.400 Gm. in 1000 cc.

Preserve as directed under normal sodium hydroxide. This solution should be frequently restandardized.

One cubic centimeter of Hundredth-Normal Sodium Hydroxide is the equivalent of:

	Gramme
Sodium Hydroxide, $NaOH$	0.0004001
Potassium Bitartrate, $KHC_4H_4O_6$	0.001882
Sulphuric Acid, H_2SO_4	0.0004904

Sodium Thiosulphate, Tenth-Normal

$Na_2S_2O_3.5H_2O = 248.20$ 24.820 Gm. in 1000 cc.

Dissolve 30 Gm. of sodium thiosulphate in sufficient distilled water, previously boiled for twenty minutes in a flask of hard glass and quickly cooled, to measure 1000 cc. Ascertain its exact strength by titration against tenth-normal potassium dichromate, in the presence of an excess of potassium iodide and a small amount of sulphuric acid, and adjust to exact normality, or to a known strength of approximate normality. The strength may also be ascertained and adjusted after titration against tenth-normal iodine. This solution should be frequently restandardized.

One cubic centimeter of Tenth-Normal Sodium Thiosulphate is the equivalent of:

	Gramme
Sodium Thiosulphate, $Na_2S_2O_3.5H_2O$	0.02482
Arsenic, As (in Arsphenamine and Neoarsphenamine)	0.003748
Bromine, Br	0.007992
Chlorine, Cl	0.003546
Chlorine, Cl (in Chloramine and Dichloramine)	0.001773
Chromium Trioxide, CrO_3	0.003333
Cupric Sulphate, anhydrous, $CuSO_4$	0.01596
Cupric Sulphate, crystallized, $CuSO_4.5H_2O$	0.02497
Iodine, I	0.01269
Iodine, I (in Thymol Iodide and Calcium Iodobehenate)	0.002115
Iron, Fe, in ferric salts	0.005584
Lead Peroxide, PbO_2	0.01196
Potassium Bromate, $KBrO_3$	0.002784
Potassium Dichromate, $K_2Cr_2O_7$	0.004903
Sodium Arsenate, anhydrous, Na_2HAsO_4	0.009299
Sodium Arsenate, crystallized, $Na_2HAsO_4.7H_2O$	0.01560
Sodium Hypochlorite, $NaOCl$	0.003723

Sodium Thiosulphate, Two-Hundredth-Normal

$Na_2S_2O_3.5H_2O = 248.20$ 1.241 Gm. in 1000 cc.

This solution should be frequently restandardized.

One cubic centimeter of Two-Hundredth-Normal Sodium Thiosulphate is the equivalent of:

	Gramme
Sodium Thiosulphate, $Na_2S_2O_3.5H_2O$	0.001241
Iodine, I	0.0006346
Iodine, I (from Thyroxin and Thyroid Glands)	0.0001058

Sulphuric Acid, Normal

$H_2SO_4 = 98.076$ 49.038 Gm. in 1000 cc.

Add slowly, with constant stirring, 30 cc. of sulphuric acid to 1020 cc. of distilled water and allow the solution to cool to 25° C. Ascertain its exact strength by titration against freshly standardized normal sodium hydroxide, methyl orange T.S. being used as indicator, and adjust to exact normality or to a known strength of approximate normality.

The strength may also be ascertained and adjusted after titration against an accurately weighed amount of reagent anhydrous sodium carbonate. It may also be standardized gravimetrically by precipitation and weighing as barium sulphate.

One cubic centimeter of Normal Sulphuric Acid is the equivalent of:

	Gramme
Sulphuric Acid, H_2SO_4	0.04904
Ammonia Gas, NH_3	0.01703
Ammonium Acetate, $NH_4C_2H_3O_2$	0.07707
Calcium Hydroxide, $Ca(OH)_2$	0.03705
Calcium Oxide, CaO	0.02804
Lithium Carbonate, Li_2CO_3	0.03695
Lithium Salicylate, $LiC_7H_5O_3$	0.1440
Magnesium Carbonate, $(MgCO_3)_4Mg(OH)_2.5H_2O$	0.04857
Magnesium Hydroxide, $Mg(OH)_2$	0.02917
Magnesium Oxide, MgO	0.02016
Methenamine, $(CH_2)_6N_4$	0.03504
Potassium Acetate, $KC_2H_3O_2$	0.09813
Potassium Bicarbonate, $KHCO_3$	0.1001
Potassium Bitartrate, $KHC_4H_4O_6$	0.1882
Potassium Carbonate, anhydrous, K_2CO_3	0.06911
Potassium Citrate, crystallized, $K_3C_6H_5O_7.H_2O$	0.1081
Potassium Hydroxide, KOH	0.05611
Potassium and Sodium Tartrate, $KNaC_4H_4O_6.4H_2O$	0.1411
Sodium Acetate, $NaC_2H_3O_2.3H_2O$	0.1361
Sodium Bicarbonate, $NaHCO_3$	0.08401
Sodium Borate, crystallized, $Na_2B_4O_7.10H_2O$	0.1909
Sodium Carbonate, anhydrous, Na_2CO_3	0.05301
Sodium Carbonate, monohydrated, $Na_2CO_3.H_2O$	0.06201
Sodium Hydroxide, NaOH	0.04001
Sodium Salicylate, $NaC_7H_5O_3$	0.16008
Zinc Oxide, ZnO	0.04069

Sulphuric Acid, Half-Normal

$H_2SO_4=98.076$ 24.519 Gm. in 1000 cc.

One cubic centimeter of Half-Normal Sulphuric Acid is the equivalent of:

	Gramme
Sulphuric Acid, H_2SO_4	0.02452
Ammonia Gas, NH_3	0.008520
Benzaldehyde, C_7H_6O	0.05304
Calcium Glycerophosphate, $CaC_3H_7PO_6$	0.10509
Calcium Lactate, anhydrous $Ca(C_3H_5O_3)_2$	0.05455
Cinnamic Aldehyde, C_9H_8O	0.03303
Citrol, $C_{10}H_{16}O$	0.07609
Lithium Citrate, anhydrous, $Li_3C_6H_5O_7$	0.03498
Lithium Citrate, crystallized, $Li_3C_6H_5O_7.4H_2O$	0.04699
Lithium Salicylate, $LiC_7H_5O_3$	0.07201
Magnesium Hydroxide, $Mg(OH)_2$	0.01459
Potassium Acetate, $KC_2H_3O_2$	0.04907
Potassium and Sodium Tartrate, anhydrous, $KNaC_4H_4O_6$	0.05254
Potassium and Sodium Tartrate, crystallized, $KNaC_4H_4O_6.4H_2O$	0.07056

Articles Employed in Chemical Testing and Reagents of the British Pharmacopœia

APPENDIX I. Br.

The British test-solutions here given are used for determining the character of particular substances, whether isolated or in composition; thus enabling us to ascertain the identity of medicines, their purity or impurity, and the character of the foreign ingredients, which may be mixed with them accidentally, or with a view to adulteration.

Acetic Acid, of the British Pharmacopœia.
Acetic Acid, Diluted, of the British Pharmacopœia.
Acetic Acid, Glacial, of the British Pharmacopœia.
Acetic Anhydride, $C_4H_6O_3$, of commerce, pure.
Acetone, of the British Pharmacopœia.
Albumen, the liquid white of fresh eggs.
Alcohol, Absolute, of the British Pharmacopœia.
Alcohol (90 per cent.). **Alcohol** (70 per cent.). **Alcohol** (20 per cent.), of the British Pharmacopœia.
Alum, Purified, of the British Pharmacopœia.
Ammonium Chloride, of the British Pharmacopœia.
Ammonium Molybdate, $(NH_4)_2MoO_4$, of commerce, pure.

Ammonium Oxalate, $(NH_4)_2C_2O_4,H_2O$, of commerce, pure.

Ammonium Persulphate, NH_4SO_4, of commerce, pure.

Ammonium Thiocyanate, NH_4SCN, of commerce, pure.

Amylic Alcohol is a liquid consisting principally of iso-primary amylic alcohol, $C_5H_{11}OH$, and may be prepared by shaking commercial fusel oil with a saturated solution of common salt, separating the oily layer, submitting it to distillation, and collecting and reserving the fraction which distils between 125° and 143° C.

Aniline, of commerce, redistilled.

Animal Charcoal, of commerce, purified.

Auric Chloride, of commerce, pure.

Barium Chloride, $BaCl_2,2H_2O$, of commerce, pure.

Barium Hydroxide, $Ba(OH)_2,8H_2O$, of commerce, pure.

Benzene, of the British Pharmacopœia.

Benzolated Amylic Alcohol, benzene, 3 parts by volume; Amylic Alcohol, 1 part by volume; mix; decant from any deposited water.

Bismuth Oxynitrate, of the British Pharmacopœia.

Borax, Purified, of the British Pharmacopœia.

Bromine, of commerce, pure.

Cadmium Iodide, CdI_2, of commerce, pure.

Calcium Carbonate, the pure white marble, or calc spar, of commerce.

Calcium Hydroxide, of the British Pharmacopœia.

Calcium Oxide, the Lime of the British Pharmacopœia.

Calcium Sulphate, $CaSO_4,H_2O$, native, pure.

Carbon Disulphide, of the British Pharmacopœia.

Carbon Tetrachloride, CCl_4, of commerce, pure.

Chlorine, a gas prepared by the interaction of hydrochloric acid and manganese peroxide, and purified by passing through a small quantity of water contained in a wash bottle.

Chloroform, of the British Pharmacopœia.

Chloroform Water, of the British Pharmacopœia.

Citric Acid, of the British Pharmacopœia.

Collodion, of the British Pharmacopœia.

Copper, Copper in foil, wire, or turnings.

Copper Acetate, $Cu(C_2H_3O_2)_2,H_2O$, of commerce, crystalline, pure.

Copper Carbonate, precipitated, of commerce.

Copper Sulphate, of the British Pharmacopœia.

Ether, of the British Pharmacopœia.

Ferric Ammonium Sulphate, $Fe_2(SO_4)_3,(NH_4)_2SO_4,24H_2O$, of commerce, pure.

Ferric Chloride, of commerce, pure, anhydrous.

Ferrous Sulphate, of the British Pharmacopœia.

Fuchsin, of commerce, pure.

Glycerin, of the British Pharmacopœia.

Hydrochloric Acid, of the British Pharmacopœia.

Hydrochloric Acid, Diluted, of the British Pharmacopœia.

Hydrochloric Acid, Gaseous, HCl, dry, prepared by the interaction of sulphuric acid and common salt.

Hydrogen Sulphide, Synonym, *Sulphuretted Hydrogen*, a gas prepared by the action of hydrochloric acid on commercial ferrous sulphide. It will be sufficiently pure after passing through two wash-bottles containing water. A solution of the gas in water may also be employed, but only if it smells strongly of the gas, and yields an abundant black precipitate with solution of lead acetate.

Hydroxylamine Hydrochloride, NH_2OH,HCl, of commerce, pure.

Hypophosphorous Acid, of commerce, specific gravity 1.137.

Indigo, a blue pigment prepared from various species of Indigofera, Linn.

Iodic Acid, HIO_3, of commerce, pure.

Iodine, of the British Pharmacopœia.

Iron, of the British Pharmacopœia.

Isinglass, the swimming bladder or sound of various species of Acipenser, Linn., prepared, and cut into shreds.

Lead Acetate, of the British Pharmacopœia.

Lead Nitrate, $Pb(NO_3)_2$, of commerce, pure.

Lead Oxide, of the British Pharmacopœia.

Lead Peroxide, PbO_2, of commerce, pure.

Lime, of the British Pharmacopœia.

Litmus, a blue pigment prepared from various species of Roccella, D.C. Litmus is used in several forms; for example, Solution of Litmus (Appendix II); Blue Litmus Paper, made by impregnating unglazed white paper with a solution of litmus; and Red Litmus Paper, made by impregnating the paper with the solution reddened by the previous addition of a very minute quantity of sulphuric acid. Litmus may also be employed in the solid form.

Magnesia, Heavy, of the British Pharmacopœia.

Manganese Peroxide, MNO_2, the powdered native pyrolusite.

Mercurous Chloride, of the British Pharmacopœia.

Methyl Orange, pure sodium dimethyl-amido-azo-benzene-sulphonate, $NaC_{14}H_{14}N_3SO_3$, of commerce.

Milk of Lime, lime, 100 grammes; distilled water, 200 millilitres; mix.

Morphinated Water, prepared by digesting pure Morphine in Chloroform Water for seven days at a temperature of 15.5° C., shaking occasionally so as to obtain a saturated solution of the alkaloid, and filtering from the undissolved morphine.

Morphine, the precipitate obtained on adding solution of ammonia, in slight excess, to the solution of a pure morphine salt in *water*, the precipitate being washed with water until free from ammonium, salt.

Mucilage of Gum Acacia, of the British Pharmacopœia.

Mucilage of Starch.—Triturate 1 gramme of Starch with a small quantity of Distilled Water to form a smooth paste; add more Distilled Water, gradually, to produce 50 millilitres of mixture; boil for a few minutes, constantly stirring; cool. Mucilage of starch must be recently prepared.

Nitric Acid, of the British Pharmacopœia.

Nitric Acid, Diluted, of the British Pharmacopœia.

Nitric Acid, Fuming, of commerce, specific gravity 1.5.

Oil of Turpentine, of the British Pharmacopœia.

Olive Oil, of the British Pharmacopœia.

Oxalic Acid, $H_2C_2O_4,2H_2O$, of commerce, pure.

Paraffin, Soft, of the British Pharmacopœia.

Petroleum Spirit, Synonym, *Petroleum Ether*, a colorless very volatile and highly inflammable liquid obtained from petroleum, and consisting of a mixture of the lower members of the paraffin series of hydrocarbon. Boiling point 50–60. Specific gravity 0.670 to 0.700.

Phenol, of the British Pharmacopœia.

Phenol-Disulphonic Acid.—Heat 3 grammes of Phenol with 20 millilitres of Sulphuric Acid on a water bath for six hours. Transfer the resulting liquid to a stoppered bottle.

Phenolphthalein, of the British Pharmacopœia.

Phosphoric Acid, Concentrated, of the British Pharmacopoeia.

Phosphoric Acid, Syrupy, of commerce, specific gravity 1.750.

Picric Acid, of the British Pharmacopœia.

Platinic Chloride, of commerce, pure.

Potassium Bichromate, of the British Pharmacopœia.

Potassium Chlorate, of the British Pharmacopœia.

Potassium Chromate, K_2CrO_4, of commerce, pure.

Potassium Cyanide, of commerce. Contains not less than 90 per cent. of pure potassium cyanide, KCN.

Potassium Ferricyanide, $K_6Fe_2C_{12}N_{12}$, of commerce, pure.

Potassium Ferrocyanide, $K_4FeC_6N_6,3H_2O$, of commerce, pure.

Potassium Hydrogen Sulphite.—Synonym—*Acid Potassium Sulphite*, $KHSO_3$, of commerce, pure.

Potassium Hydroxide of the British Pharmacopœia.

Potassium Iodide of the British Pharmacopœia.

Potassium Nitrate of the British Pharmacopœia.

Potassium Permanganate of the British Pharmacopœia.

Potassium Sulphate of the British Pharmacopœia.

Resorcin of the British Pharmacopœia

Salicylic Acid of the British Pharmacopœia.

Sodium Acetate, $NaC_2H_3O_2,3H_2O$, of commerce, pure.

Sodium Acetate, Anhydrous, $NaC_2H_3O_2$, of commerce, pure.

Sodium Arsenate, Anhydrous of the British Pharmacopœia.

Sodium Bicarbonate of the British Pharmacopœia.

Sodium Carbonate of the British Pharmacopœia.

Sodium Carbonate, Exsiccated of the British Pharmacopœia.

Sodium Chloride of the British Pharmacopœia.

Sodium Hydrogen Sulphite.—Synonym—*Acid Sodium Sulphite*, $NaHSO_3$, of commerce, pure.

Sodium Hydroxide of commerce, purified by means of alcohol.

Sodium Nitrite of the British Pharmacopœia.

Sodium Potassium Tartrate of the British Pharmacopœia.

Sodium Sulphate of the British Pharmacopœia.

Sodium Sulphate, Anhydrous, The Sodium Sulphate of the British Pharmacopœia, rendered anhydrous by heat.

Sodium Sulphide, $Na_2S,9H_2O$, of commerce, pure.

Sodium Sulphite of the British Pharmacopœia.

Sodium Thiosulphate, $Na_2S_2O_3,5H_2O$, of commerce, pure.

Sugar, Refined of the British Pharmacopœia.

Sulphur, Precipitated of the British Pharmacopœia.

Sulphuric Acid of the British Pharmacopœia.

Sulphuric Acid, Diluted, of the British Pharmacopœia.

Talc, Powdered, a natural magnesium silicate, powdered and purified by boiling with dilute hydrochloric acid, washing with distilled water until neutral to litmus, and drying.

Tartaric Acid of the British Pharmacopœia.

Tin, granulated by letting drops of the metal in the molten state fall into water. Yields no characteristic reactions for lead, copper, iron, or zinc.

Turmeric, the dried rhizome of Curcuma, Longa, *Linn.* It is usually employed in the form of a tincture prepared by the process of maceration, from the bruised rhizome, in the proportion of 1 gramme to 6 millilitres of Alcohol (90 per cent.), or in the form of paper prepared by steeping unglazed white paper in the tincture and drying.

Water, the Distilled Water of the British Pharmacopœia.

Zinc, the laminated or granulated metal. Completely dissolved by diluted hydrochloric acid, the solution yielding no characteristic reactions for lead, copper, cadmium, arsenic, tin or iron.

Zinc Carbonate of the British Pharmacopœia.

APPENDIX II. Br.

Solutions Employed in Chemical Testing.

(*Br.*)

Solution of Albumen.—Albumen, 20 millilitres; Distilled Water, 80 millilitres. Mix by trituration in a mortar, and filter through clean tow previously moistened with Distilled Water. Solution of Albumen must be recently prepared. The strength of the Solution may be adjusted to suit particular requirements.

Solution of Ammonia, of the British Pharmacopœia.

Solution of Ammonia, Strong, of the British Pharmacopœia.

Solution of Ammonium Acetate, of the British Pharmacopœia.

Solution of Ammonium Carbonate.—Ammonium Carbonate, 5.0 grammes; Solution of Ammonia, 7.5 millilitres; Distilled Water, sufficient to produce 100.0 millilitres; dissolve; filter if necessary.

Solution of Ammonium Chloride.—Ammonium Chloride, 10 grammes; Distilled Water sufficient to produce 100 millilitres; dissolve; filter if necessary.

Solution of Ammonium Chloride (Nessler's).—Ammonium Chloride, 3.15 grammes; Distilled Water, free from ammonia, sufficient to produce 1000.00 millilitres; dissolve.

Solution of Ammonium Chloride, Dilute, (Nessler's) .—Solution of Ammonium Chloride, (Nessler's) 10 millilitres; Distilled Water, free from ammonia, sufficient to produce 1000 millilitres; Mix.

Solution of Ammonium Citrate, of the British Pharmacopœia.

Solution of Ammonium Hydrosulphide.—Saturate one hundred and twenty millilitres of Solution of Ammonia with washed Hydrogen Sulphide; add eighty millilitres of Solution of Ammonia. This solution must be recently prepared.

Solution of Ammonium Molybdate.—Ammonium Molybdate, 10 grammes; Distilled Water, sufficient to produce 100 millilitres; dissolve; filter if necessary.

Solution of Ammonium Oxalate.—Ammonium Oxalate, 2.5 grammes; Distilled Water sufficient to produce 100.0 millilitres; dissolve; filter if necessary.

Solution of Auric Chloride.—Auric Chloride, 2 grammes; Distilled Water, sufficient to produce 100 millilitres; dissolve; filter if necessary.

Solution of Barium Chloride.—Barium Chloride, in crystals, 10 grammes; Distilled Water sufficient to produce 100 millilitres; dissolve; filter if necessary.

Solution of Barium Hydroxide.—Barium Hydroxide, 3 grammes; Distilled Water, recently boiled, sufficient to produce 100 millilitres; dissolve; filter if necessary.

Solution of Boric Acid.—Boric Acid, 2.5 grammes; Alcohol (90 per cent.) sufficient to produce 100.0 millilitres; dissolve; filter if necessary.

Solution of Bromine.—A saturated solution of Bromine in Distilled Water.

Solution of Cadmium Iodide.—Cadmium Iodide, 5 grammes; Distilled Water, sufficient to produce 100 millilitres; dissolve; filter if necessary.

Solution of Calcium Chloride.—Calcium Chloride 10 grammes; Distilled Water, sufficient to produce 100 millilitres; dissolve; filter if necessory.

Solution of Calcium Sulphate.—A saturated solution of Calcium Sulphate in Distilled Water.

Solution of Chlorinated Soda.—Solution of Chlorinated Soda of the British Pharmacopœia.

Solution of Chlorine.—A saturated solution of Chlorine in Distilled Water. This Solution must be recently prepared.

Solution of Chromic Acid, of the British Pharmacopœia.

Solution of Copper Acetate.—Copper Acetate, 5 grammes; Distilled Water, sufficient to produce 100 millilitres; dissolve; filter if necessary.

Solution of Copper Acetate, Diluted.—Solution of Copper Acetate, 1 millilitre; Distilled Water sufficient to produce 100 millilitres. Mix.

Solution of Copper Ammonio-Sulphate.—Copper Sulphate, in crystals, 5 grammes; Solution of Ammonia, a sufficient quantity; Distilled Water sufficient to repoduce 100 millilitres. Dissolve the Copper Sulphate in one hundred and sixty millilitres of the Distilled Water, and cautiously add the Solution of Ammonia to the liquid until the precipitate first formed is nearly dissolved; filter the product; finally add to the filtrate sufficient of the Distilled Water to produce the required volume.

Solution of Copper Oxide, Ammoniacal.—Copper Carbonate, 5 grammes; Strong Solution of Ammonia, 100 millilitres. Shake together occasionally during twelve hours; set aside for twenty-four hours, and pour off the clear liquid. This solution must be recently prepared.

Solution of Copper Sulphate.—Copper Sulphate, 10 grammes; Distilled Water, sufficient to produce 100 millilitres; dissolve; filter if necessary.

Solution of Ferric Sulphate.—Solution of Ferric Sulphate of the British Pharmacopœia.

Solution of Ferrous Sulphate.—Ferrous Sulphate, 2 grammes; Distilled Water, sufficient to produce 100 millilitres; dissolve; filter if necessary. This Solution must be recently prepared.

Solution of Formaldehyde, of the British Pharmacopœia.

Solution of Fuchsin, Decolorized.—Dissolve one gramme of Fuchsin in five hundred millilitres of hot Distilled Water; add slowly twenty millilitres of a saturated aqueous solution of Acid Sodium Sulphite and then, also slowly, ten millilitres of Hydrochloric Acid, the mixture being kept well shaken. Cool and add sufficient Distilled Water to produce one thousand millilitres.

Solution of Hydrogen Peroxide of the British Pharmacopœia.

Solution of Indigo Sulphate.—Indigo dry and in fine powder, 0.1 gramme; Sulphuric Acid 100.0 millilitres. Mix the Indigo with one millilitre of the Sulphuric Acid in a small test-tube, and heat in boiling water for an hour; pour the product into the remainder of the Sulphuric Acid; shake the mixture; decant the clear liquid.

Solution of Isinglass.—Isinglass, 2 grammes; Distilled Water, sufficient to produce 100 millilitres. Mix, and digest for half an hour on a water-bath with repeated shaking; filter through clean tow previously moistened with Distilled Water. This Solution must be recently prepared.

Solution of Lead Acetate.—Lead Acetate, 10 grammes; Distilled Water, recently boiled, sufficient to produce 100 millilitres; dissolve; filter if necessary.

Solution of Lead Subacetate.—The Strong Solution of Lead Subacetate of the British Pharmacopœia diluted, if necessary, with Distilled Water.

Solution of Lime.—Synonym—*Solution of Calcium Hydroxide;* of the British Pharmacopœia.

Solution of Litmus.—Litmus in powder, 10 grammes; Alcohol (90 per cent.), 100 millilitres; Distilled Water, 100 millilitres. Boil the Litmus with forty millilitres of the Alcohol for one hour; pour away the clear liquid; repeat this operation with thirty millilitres of the Alcohol, and a third time with the remainder of the Alcohol. Digest the washed Litmus in the Distilled Water, and filter.

Solution of Magnesium Ammonio-Sulphate.—Magnesium Sulphate, 10 grammes; Ammonium Chloride 20 grammes; Solution of Ammonia, 42 millilitres; Distilled Water, 80 millilitres. Dissolve the Magnesium Sulphate and Ammonium Chloride in the Distilled Water; add the Solution of Ammonia, and set the mixture aside for a few days in a well-closed bottle; decant and filter.

Solution of Magnesium Sulphate.—Magnesium Sulphate, 10 grammes; Distilled Water sufficient to produce 100 millilitres; dissolve; filter if necessary.

Solution of Mercurous Nitrate.—Mercury, 2 grammes; Nitric Acid, 1 millilitre: Distilled Water, a sufficient quantity. To the Mercury, in a small dish, add one millilitre of Distilled Water and the Nitric Acid, and set the whole aside for twenty-four hours in a cool dark place; drain the resulting crystals; dissolve them in two hundred nillilitres of Distilled Water.

Solution of Mercury Nitrate.—Synonym—*Millon's Reagent.* Mercury, 3 millilitres; Fuming Nitric Acid, 27 millilitres; Distilled Water, a sufficient quantity. Dissolve the Mercury in the Fuming Nitric Acid without heat; dilute the solution with an equal volume of Distilled Water. This solution must be recently prepared.

Solution of Methyl Orange.—Methyl Orange, 0.2 gramme; Alcohol (90 per cent.), 25.0 millilitres; Distilled Water, sufficient to produce 100.0 millilitres; dissolve.

Solution of Phenolphthalein.—Phenolphthalein, 0.2 gramme; Alcohol (90 per cent.), 60.0 millilitres; Distilled Water, sufficient to produce 100.0 millilitres; dissolve.

Solution of Picric Acid.—Picric Acid, 0.66 gramme; Distilled Water, sufficient to produce 100.00 millilitres; dissolve.

Solution of Platinic Chloride.—Platinic Chloride, 5 grammes; Distilled Water, sufficient to produce 100 millilitres; dissolve.

Solution of Potassio-Cupric Tartrate.—Synonym—*Fehling's Solution.*

No. 1. Copper Sulphate, in crystals, 34.64 grammes; Sulphuric Acid, 0.50 millilitre; Distilled Water, sufficient to produce 500.00 millilitres; dissolve.

No. 2. Sodium Potassium Tartrate, 176 grammes; Sodium Hydroxide, 77 grammes; Distilled Water sufficient to produce 500 millilitres; dissolve. Mix equal volumes of the solutions No. 1 and No. 2 at the time of using.

Solution of Potassio-Mercuric Iodide.—Synonym—*Mayer's Reagent.* Mercuric Chloride, 1.355 grammes; Potassium Iodide, 5.000 grammes; Distilled Water, sufficient to produce 100.000 millilitres. Dissolve the Mercuric Chloride in sixty millilitres of the Distilled Water; dissolve the Potassium Iodide in twenty millilitres of the Distilled Water; mix the two solutions, and add sufficient Distilled Water to produce the required volume.

Solution of Potassio-Mercuric Iodide, Alkaline.—Synonym—*Nessler's Reagent.* Potassium Iodide, 3.5 grammes; Mercuric Chloride, sufficient quantity; Sodium Hydroxide, 12.0 grammes; Distilled Water sufficient to produce 100.0 millilitres. Dissolve the Potassium Iodide and one and a quarter grammes, of Mercuric Chloride in eighty millilitres of Distilled Water; to this liquid add a cold saturated aqueous solution of Mercuric Chloride, with constant stirring, until a slight red precipitate remains; add the Sodium Hydroxide and dissolve; then add a little more of the aqueous solution of Mercuric Chloride, and sufficient Distilled Water to produce the required volume.

Solution of Potassium Acetate.—Potassium Acetate, 10 grammes; Distilled Water sufficient to produce 100 millilitres; dissolve; filter if necessary.

Solution of Acid Potassium Tartrate.—A saturated solution of Acid Potassium Tartrate in Distilled Water.

Solution of Potassium Carbonate.—Potassium Carbonate, 10 grammes; Distilled Water sufficient to produce 100 millilitres; dissolve; filter if necessary.

Solution of Potassium Chromate.—Potassium Chromate, 10 grammes; Distilled Water, sufficient to produce 100 millilitres; dissolve; filter if necessary.

Solution of Potassium Cyanide.—Potassium Cyanide, 10 grammes; Distilled Water, 100 millilitres; dissolve; filter if necessary.

Solution of Potassium Ferricyanide.—Potassium Ferricyanide, in crystals, 5 grammes; Distilled Water, sufficient to produce 100 millilitres; dissolve; filter if necessary. This Solution must be recently prepared.

Solution of Potassium Ferrocyanide.—Potassium Ferrocyanide in crystals, 5 grammes; Distilled Water, sufficient to produce 100 millilitres; dissolve; filter if necessary.

Solution of Potassium Hydroxide, of the British Pharmacopœia.

Solution of Potassium Hydroxide, Alcoholic.—Potassium Hydroxide, 10 grammes; Alcohol (90 per cent.), sufficient to produce 100 millilitres; dissolve; filter if necessary.

Solution of Potassium Iodide.—Potassium Iodide, 10 grammes; Distilled Water, sufficient to produce 100 millilitres; dissolve; filter if necessary.

Solution of Potassium Permanganate of the British Pharmacopœia.

Solution of Pyroxylin, the Collodion of the British Pharmacopœia.

Solution of Silver Ammonio-Nitrate.—Silver Nitrate, in crystals, 2.5 grammes; Solution of Ammonia, 10.0 millilitres, or a sufficient quantity; Distilled Water, sufficient to produce 100.0 millilitres. Dissolve the Silver Nitrate in eighty millilitres of the Distilled Water, and cautiously add the Solution of Ammonia to the liquid until the precipitate first formed is nearly dissolved; set aside; decant; finally add sufficient Distilled Water to produce the required volume.

Solution of Silver Nitrate.—Silver Nitrate, 5 grammes; Distilled Water, sufficient to produce 100 millilitres; dissolve.

Solution of Sodium Acetate.—Sodium Acetate, 10 grammes; Distilled Water, sufficient to produce 100 millilitres; dissolve; filter if necessary.

Solution of Sodium Carbonate.—Sodium Carbonate, 10 grammes; Distilled Water, sufficient to produce 100 millilitres; dissolve; filter if necessary.

Solution of Sodium Hydroxide.—Sodium Hydroxide, 20 grammes; Distilled Water, sufficient to produce 100 millilitres; dissolve; filter if necessary.

Solution of Sodium Phosphate.—Sodium phosphate in crystals, 10 grammes; Distilled Water, sufficient to produce 100 millilitres; dissolve; filter if necessary.

Solution of Sodium Sulphate.—Sodium Sulphate, 10 grammes; Distilled Water, sufficient to produce 100 millilitres; dissolve; filter if necessary.

Solution of Sodium Sulphide.—Sodium Sulphide, 10 grammes; Distilled Water, sufficient to produce 100 millilitres; dissolve; filter if necessary.

Solution of Stannous Chloride.—Tin, granulated, 20 grammes; Hydrochloric Acid, 60 millilitres; Distilled Water, sufficient to produce 100 millilitres. Dilute the hydrochloric Acid with twenty millilitres of the Distilled Water, and having the added Tin, apply heat gently until gas ceases to be evolved; add sufficient Distilled Water to produce the required volume, allowing the dissolved Tin to remain in the Solution.

Solution of Sulphurous Acid, of the British Pharmacopœia.

Solution of Tannic Acid.—Tannic Acid, 10 grammes; Distilled Water, sufficient to produce 100 millilitres; dissolve. This Solution must be recently prepared.

Solution of Tartarated Antimony.—Tartarated Antimony, 5 grammes; Distilled Water, boiling, sufficient to produce 100 millilitres; dissolve; filter if necessary.

Solution of Tartaric Acid.—Tartaric Acid, in crystals, 12.5 grammes; Alcohol (90 per cent.), 25.0 millilitres; Distilled Water, sufficient to produce 100.0 millilitres. Dissolve the Tartaric Acid in sixty millilitres of the Distilled Water; add the Alcohol; add sufficient Distilled Water to produce the required volume.

Test-Solution of Ferric Chloride (T. Sol.).—Ferric Chloride, 5 grammes; Distilled Water, sufficient to produce 100 millilitres; dissolve; filter if necessary.

Test-Solution of Mercuric Chloride (T. Sol.).—Mercuric Chloride, 5 grammes; Distilled Water, sufficient to produce 100 millilitres; dissolve; filter if necessary.

APPENDIX III. Br.

Solutions Employed in Volumetric Determinations.

(Br.)

Solution of Ammonium Thiocyanate, N/10.—Ammonium Thiocyanate dissolved in Distilled Water to contain in 1000 millilitres 7.612 grammes of ammonium thiocyanate, NH_4SCN.

Solution of Hydrochloric Acid, N/1, N/10.—Hydrochloric Acid diluted with Distilled Water to contain in 1000 millilitres the following quantities of hydrochloric acid, HCl: for N/1, 36.468 grammes HCl: for N/10, 3.646 grammes HCl.

Solution of Hydroxylamine Hydrochloride, N/2.—Hydroxylamine Hydrochloride dissolved in a mixture of equal volumes of Alcohol (90 per cent.) and Alcohol (70 per cent.) to contain in 1000 millilitres 34.751 grammes of hydroxylamine hydrochloride, NH_2OH,HC.

Solution of Iodine, N/10.—Iodine and Potassium Iodide dissolved in Distilled Water to contain in 1000 millilitres 12.692 grammes of iodine, I, and 18 grammes of Potassium Iodide.

Solution of Oxalic Acid, N/1, N/10.—Oxalic Acid dissolved in Distilled Water to contain in 1000 millilitres the following quantities of oxalic acid, $H_2C_2O_4,2H_2O$: for N/1, 63.024 grammes $H_2C_2O_4,2H_2O$: for N/10, 6.302 grammes $H_2C_2O_4$, $2H_2O$.

Solution of Potassium Bichromate, N/1, N/10.—Potassium Bichromate dissolved in Distilled Water to contain in 1000 millilitres the following quantities of potassium bichromate, $K_2Cr_2O_7$: for N/1, 49.033 grammes $K_2Cr_2O_7$; for N/10, 4.903 grammes $K_2Cr_2O_7$.

Solution of Potassium Hydroxide, Alcoholic, N/1, N/2, N/10.—Potassium Hydroxide dissolved in Alcohol (90 per cent.) to contain in 1000 millilitres the following quantities of potassium hydroxide, KOH: for N/1, 56.108 grammes KOH; for N/2, 28.054 grammes KOH; for N/10, 5.610 grammes KOH. These Solutions are colourless, or not more than faintly yellow.

Solution of Potassium Permanganate, N/10.—Potassium Permanganate dissolved in Distilled Water to contain in 1000 millilitres 3.161 grammes of potassium permanganate, $KMnO_4$.

Solution of Silver Nitrate, N/10.—Silver Nitrate dissolved in Distilled Water to contain in 1000 millilitres 16.989 grammes of silver nitrate, $AgNO_3$.

Solution of Sodium Hydroxide, N/1, N/2, N/5, N/10, N/20.—Sodium Hydroxide dissolved in Distilled Water to contain in 1000 millilitres the following quantities of sodium hydroxide, $NaOH$: for N/1, 40.008 grammes $NaOH$; for N/2, 20.004 grammes $NaOH$; for N/5, 8.001 grammes $NaOH$; for N/10, 4.000 grammes $NaOH$; for N/20, 2.000 grammes $NaOH$.

Solution of Sodium Thiosulphate, N/10.—Sodium Thiosulphate dissolved in Distilled Water to contain in 1000 millilitres 24.822 grammes of sodium thiosulphate, $Na_2S_2O_3,5H_2O$.

Solution of Sulphuric Acid, N/1, N/2, N/10, N/20, N/100.—Sulphuric Acid diluted with Distilled Water to contain in 1000 millilitres the following quantities of sulphuric acid, H_2SO_4: for N/1, 49.043 grammes H_2SO_4; for N/2, 24.521 grammes H_2SO_4; for N/10, 4.904 grammes H_2SO_4; for N/20, 2.452 grammes H_2SO_4; for N/100, 0.490 gramme H_2SO_4.

Indicators of the Termination of Reactions in Volumetric Determinations.

(Br.)

Mucilage of Starch.—It gives an intensely blue colour with iodine, at ordinary temperatures.

Solution of Ferric Sulphate, of the British Pharmacopœia, gives a deep red colour with ammonium thiocyanate.

Solution of Litmus.—It gives a red colour with acids and a blue colour with alkalies. Carbon dioxide, if present in the solution, must be previously expelled by boiling.

Solution of Methyl Orange.—It gives a pink colour with mineral acids and a yellow colour with alkalies.

Solution of Phenolphthalein, gives with alkalies a red colour, which is discharged by acids.

Solution of Potassium Ferricyanide, gives an intensely blue precipitate or coloration with ferrous salts, but none with ferric salts.

Tincture of Cochineal, of the British Pharmacopœia, gives a purple colour with alkalies and a brownish-yellow colour with acids.

APPENDIX IV. Br.

Reactions and Tests for Substances Mentioned in the Text of the British Pharmacopœia.

(*Br.*)

Acetates.—Neutral acetates are decomposed by heat, yielding vapours which possess a characteristic acetous odour. Hydrogen acetate and ethyl acetate have characteristic odours. Acetates when warmed with *sulphuric acid* yield vapours of hydrogen acetate; or, when warmed with *sulphuric acid* and a small quantity of *alcohol* (90 per cent.), yield ethyl acetate. *T. Sol. of ferric chloride* produces a deep-red coloration with neutral or faintly acid acetates, and the resulting liquid on boiling yields a reddish-brown precipitate. On adding *hydrochloric acid* the red solution turns yellow.

Aluminium.—*Solution of ammonia* or *solution of ammonium hydrosulphide* produces a white gelatinous precipitate, soluble in *hydrochloric acid*, in *acetic acid*, and in *solution of sodium hydroxide*, but nearly insoluble in *solution of ammonia* and in solutions of ammonium salts, and quite insoluble when the solutions are boiled.

Ammonium Salts.—Ammonium salts volatilise when strongly heated, generally without residue. When heated with *solution of sodium hydroxide*, ammonia is evolved, recognisable by its odour. *Solution of platinic chloride* produces with ammonium salts acidified with *hydrochloric acid* a yellow crystalline precipitate, especially in the presence of alcohol. On ignition, this precipitate leaves a residue of platinum only.

Antimony.—*Hydrogen sulphide* produces, in slightly acid solutions, an orange-coloured precipitate, soluble in *solution of sodium hydroxide*, and *of ammonium hydrosulphide*, and in warm *hydrochloric acid* with evolution of hydrogen sulphide, but almost insoluble in solution of Ammonium Carbonate. Nascent hydrogen, generated by the interaction of *zinc* and *diluted sulphuric acid*, partially converts antimony compounds into hydrogen antimonide. A cold porcelain tile held in the flame of this gas acquires a dark metallic deposit which is not appreciably dissolved by *solution of chlorinated soda*. Nascent hydrogen, generated by the interaction of *zinc* and *solution of sodium hydroxide*, does not convert antimony into hydrogen antimonide. If one end of a strip or rod of *zinc* be allowed to rest on a platinum capsule containing an acidified solution of an antimony compound, the other end being in the solution, the antimony is precipitated on the platinum as a black, adherent, non-granular stain, insoluble in *hydrochloric acid*. Bright *copper* foil precipitates antimony from solutions, and the antimony may be volatilised by heat in an open tube, condensing as a white amorphous sublimate of oxides of antimony near to the copper.

Arsenic.—*Hydrogen sulphide* produces in solutions containing *hydrochloric acid* a yellow precipitate, soluble in *solution of sodium hydroxide*, and *of ammonium hydrosulphide*, and in solution of Ammonium Carbonate, but reprecipitated on addition of *hydrochloric acid*. The precipitate is insoluble in *hydrochloric acid*. Nascent hydrogen, generated by the interaction of *zinc* and *diluted sulphuric acid*, converts arsenic compounds into hydrogen arsenide. A cold porcelain tile held in the flame of this gas acquires a dark metallic deposit, which is readily dissolved by *solution of chlorinated soda*. Nascent hydrogen, generated by the interaction of *zinc* and *solution of sodium hydroxide*, converts arsenic compounds into hydrogen arsenide. This gas gives a black stain to filter-paper soaked with *solution of silver nitrate* and placed as a cap over the tube in which the test is being performed. Bright *copper* foil precipitates arsenic from solutions acidified by *hydrochloric acid*, and the arsenic may be volatilised by heat in an open tube, and condenses, at some distance from the copper, as a white sublimate of characteristic octahedral crystals of arsenious oxide.

ARSENITES.—Solutions of arsenites yield a yellow precipitate with *solution of silver ammonio-nitrate*.

ARSENATES.—Solutions of arsenates yield a reddish-chocolate precipitate with *solution of silver ammonio-nitrate. Solution of magnesium ammonio-sulphate* produces a white crystalline precipitate.

Bicarbonates. *See* **Carbonates.**

Bismuth.—*Hydrogen sulphide* produces a brownish-black precipitate, insoluble in *solution of sodium hydroxide*, in *diluted hydrochloric acid* and in *solution of ammonium hydrosulphide*, but soluble in warm *nitric acid. Solution of sodium hydroxide*, or of *ammonia*, except in the presence of citrates, produces a white precipitate insoluble in excess of the precipitant. Dilute solution of *sodium chloride* in large excess produces in solutions which are not too acid a white precipitate, insoluble in *solution of tartaric acid*.

Bromates.—From bromates *solution of sulphurous acid* liberates bromine, recognisable by its odour and appearance. After ignition with charcoal bromates are converted into bromides, and the latter yield their characteristic reactions.

Bromides.—*Solution of silver nitrate* produces a yellowish curdy precipitate, somewhat soluble in strong but almost insoluble in diluted *solution of ammonia*, and insoluble in *nitric acid. Solution of chlorine* liberates bromine, soluble in two or three drops of *carbon disulphide* or of *chloroform*, and forming a reddish solution. Bromine is liberated when a bromide is heated with *sulphuric acid* and *manganese peroxide*, or *potassium bichromate*, the vapour giving an orange-yellow colour to filter-paper soaked in *mucilage of starch*. In testing for bromides in the presence of iodides, all iodine should first be removed by boiling the aqueous solution with excess of *lead peroxide*.

Cadmium.—*Hydrogen sulphide* produces a yellow precipitate, insoluble in cold *diluted hydrochloric acid*, in *solution of ammonium hydrosulphide* and in *solution of sodium hydroxide*, but soluble in *nitric acid*, in hot *diluted hydrochloric acid*, and in hot *diluted sulphuric acid. Solution of sodium hydroxide* produces a white precipitate insoluble in excess. *Solution of ammonia* produces a white precipitate readily soluble in excess.

Calcium.—*Solution of ammonium carbonate* produces a white precipitate which, after well boiling and allowing to cool, is insoluble in *solution of ammonium chloride. Solution of ammonium oxalate* produces a white precipitate, soluble in *hydrochloric acid* but insoluble in *acetic acid. Solution of potassium chromate* produces no precipitate.

Carbonates and Bicarbonates.—Dilute acids liberate carbonic acid; the escaping gas is odourless, and produces a white precipitate in *solution* of lime. Soluble carbonates produce a brownish-red precipitate with *T. Sol. of mercuric chloride,* bicarbonates a whitish precipitate; the former produce a white precipitate with cold *solution of magnesium sulphate,* the latter do not.

Chlorides.—*Solution of silver nitrate* produces a white curdy precipitate, soluble in *solution of ammonia,* but insoluble in *nitric acid.* A solid chloride or hydrochloride when subjected to distillation with *sulphuric acid* and *potassium bichromate,* yields a reddish-brown distillate which is decomposed by *water.* The resulting solution when nearly neutralized produces a yellow precipitate with *solution of lead acetate,* Heated with *manganese peroxide* and *sulphuric acid,* chlorides yield chlorine, recognisable by its odour and by giving a blue colour with *solution of potassium iodide* and *mucilage of starch.*

Citrates.—Citrates become charred when heated. *Solution of Calcium Chloride* added in excess produces, when boiled with a neutral solution of a citrate, a white precipitate in solutions of neutral citrates a white precipitate soluble in *solution of amonia.* A mirror is not formed on the sides of the tube when the ammoniacal solution is warmed.

Copper.—*Hydrogen sulphide* produces a brownish-black precipitate, insoluble in *diluted hydrochloric acid* and in *solution of sodium hydroxide,* almost insoluble in *solution of ammonium hydrosulphide,* but decomposed and dissolved by boiling *nitric acid. Solution of sodium hydroxide* produces a bulky light-blue precipitate which becomes brownish-black on boiling. *Solution of ammonia* added in small quantity to a neutral solution of a copper salt produces a greenish-blue precipitate which readily dissolves in excess of the precipitant, forming a deep- blue solution. *Solution of potassium ferrocyanide* produces a reddish-brown precipitate, or in very dilute solutions a reddish-brown coloration.

Cyanides.—*Solution of silver nitrate* produces a white curdy precipitate, soluble in *solution of potassium cyanide,* in *solution of ammonia,* and in boiling *nitric acid.* When to a soluble cyanide there are added a few drops of a mixed solution of ferrous and ferric salts, then of *solution of sodium hydroxide,* and lastly excess of *hydrochloric acid,* a blue precipitate is produced. Mercury cyanide and silver cyanide decompose when heated, evolving (highly poisonous) cyanogen, which burns with a pink flame.

Iodates.—*Solution of silver nitrate* produces a white precipitate sparingly soluble in *water* and in *diluted nitric acid,* but readily dissolved by *solution of ammonia. Solution of sulphurous acid* when added to the ammoniacal solution produces a pale yellow precipitate. A mixed *solution of potassium iodide* and *tartaric acid* added to a solution of an iodate liberates iodine, which produces a blue colour with *mucilage of starch. Solution of barium chloride* produces a white precipitate nearly insoluble in *water* and soluble with difficulty in *diluted nitric acid.* On the addition of *mucilage of starch* and *solution of sulphurous acid* a blue colour is produced.

Iodides.—*Solution of silver nitrate* produces a curdy yellow precipitate, insoluble in *nitric acid* and almost insoluble in *solution of ammonia. T. Sol. of mercuric chloride* produces a scarlet precipitate, slightly soluble in excess of this reagent, and very soluble in *solution of potassium iodide.* A small quantity of *solution of chlorine* added to a solution of an iodide liberates iodine, which colours *carbon disulphide* violet and *mucilage of starch* deep blue. Heated with *sulphuric acid* and *manganese peroxide* or *potassium bichromate* violet vapours of iodine are evolved.

Iron.—Reaction common to Ferrous and Ferric salts: *Solution of ammonia hydrosulphide* produces, in neutral solutions, a black precipitate soluble in cold *diluted hydrochloric acid* with evolution of hydrogen sulphide. Reactions characteristic of Ferrous salts: *Solution of potassium ferrocyanide* produces a white precipitate, rapidly turning blue, insoluble in *diluted hydrochloric acid. Solution of potassium ferrocyanide* produces a dark-blue precipitate, insoluble in *diluted hydrochloric acid;* decomposed by *solution of sodium hydroxide. Solution of sodium hydroxide* produces a dull-green precipitate. Reactions characteristic of Ferric salts: *Solution of ammonium thiocyanate* produces a blood-red coloration which is discharged on the addition of *T. Sol. of mercuric chloride. Solution of potassium ferricyanide* produces a reddish-brown coloration but no precipitate. *Solution of potassium ferrocyanide* produces a dark-blue precipitate, insoluble in *diluted hydrochloric acid. Solution of sodium hydroxide* produces a reddish-brown precipitate, soluble in solution of *citric acid* or *tartaric acid,* and not formed in the presence of citrates or tartrates.

Lead.—*Hydrochloric acid* produces except in very weak solutions, a white precipitate, soluble in boiling *water,* but re-deposited in crystals on cooling. *Hydrogen sulphide,* in not very strongly acid solutions, produces a black precipitate insoluble in *diluted hydrochloric acid, solution of potassium hydroxide,* and *solution of ammonium hydrosulphide,* but soluble in hot *diluted nitric acid. Diluted sulphuric acid* produces a white precipitate almost insoluble in *water,* and still less soluble in *diluted sulphuric acid* or in *alcohol* (96 per cent.), but soluble in *solution of ammonium acetate. Solution of potassium chromate* produces a yellow precipitate readily soluble in *solution of sodium hydroxide,* in hot *nitric acid,* sparingly soluble in *diluted nitric acid,* insoluble in *acetic acid.*

Magnesium.—*Solution of ammonium carbonate,* in the presence of *solution of ammonium chloride,* produces no precipitate. *Solution of sodium phosphate* in the presence of ammonium salts and *solution of ammonia,* produces a white crystalline precipitate. *Solution of sodium hydroxide* produces a white precipitate, insoluble in excess of the reagent, but soluble in *solution of ammonium chloride.*

Mercury.—Reactions common to Mercurous and Mercuric salts: *Hydrogen sulphide* produces a black precipitate, insoluble in *solution of ammonium hydrosulphide* and in boiling *diluted nitric acid.* Bright *copper* foil immersed in a solution free from excess of nitric acid becomes coated with a deposit of mercury which on rubbing becomes bright; the mercury may be volatilised from the foil by heat and obtained in globules. Reaction characteristic of Mercurous salts: *Hydrochloric acid* produces a white precipitate insoluble in *water,* and blackened by *solution of ammonia.* Reactions characteristic of Mercuric salts: *Solution of sodium hydroxide* produces a yellow precipitate. *Solution of potassium iodide* produces in neutral solutions a scarlet precipitate soluble in excess of the preciptant, and in a considerable excess of the solution of the mercuric salt.

Nitrates.—*Ferrous sulphate* and *sulphuric acid,* when added to a solution of a nitrate in such a way that the acid forms a stratum below the aqueous solution, produce a brown coloration at the junction of the two liquids. Nitrates liberate red fumes when warmed with *sulphuric acid* and *copper*.

Nitrites.—On the addition to a solution of a nitrite, of a few drops of diluted sulphuric acid, solution of potassium iodide and mucilage of starch, a blue colour is produced. Diluted sulphuric acid produces red fumes. Solution of ferrous sulphate produces a deep brown colour.

Oxalates.—*Solution of calcium chloride* produces a white precipitate soluble in *hydrochloric acid* but insoluble in *acetic acid. Solution of silver nitrate* produces a white precipitate, soluble in *solution of ammonia* and in diluted nitric acid. Oxalates do not char when heated with sulphuric acid but yield carbon monoxide and carbon dioxide.

Phosphates.—*Solution of silver ammonio-nitrate* produces in salt solutions of ortho-phosphates a light-yellow precipitate readily soluble in *solution of ammonia* and in cold *diluted nitric acid. Solution of magnesium ammonio-sulphate* produces a white crystalline precipitate. Excess of *solution of ammonium molybdate* containing much *nitric acid,* produces on warming, a yellow precipitate.

Potassium.—*Solution of platinic chloride* produces with moderately strong solutions of potassium chloride (or with other potassium salts if hydrochloric acid be present) a yellow crystalline precipitate, which, upon ignition, leaves a residue of potassium chloride and platinum. Potassium compounds moistened with *hydrochloric acid* when introduced, on platinum wire, into the flame of a Bunsen burner, communicate to the flame a violet coloration.

Selenium and Tellurium.—Selenium and Tellurium may occur in compounds of bismuth. To detect these elements, dissolve the compound in *nitric acid,* add solution of *sodium chloride* or *solution of ammonium chloride,* and dilute freely with *water.* The filtrate from the precipitate, mixed with excess of an aqueous solution of *sodium sulphite,* produces no precipitate or coloration even after twelve hours.

Silica.—Silica after exposure to a red heat, is insoluble in acids, and is not dissolved in a bead of *purified borax* when heated to fusion in the blowpipe flame. The result of its fusion with *sodium carbonate* is soluble in water, the solution yielding a gelatinous precipitate on the addition of *hydrochloric acid.*

Silver.—*Hydrochloric acid* and other chlorides produce a white curdy precipitate, soluble in *solution of ammonia* but insoluble in *nitric acid. Solution of Potassium chromate* produces a red precipitate, soluble in *nitric acid.*

Sodium.—Sodium compounds, moistened with *hydrochloric acid,* when introduced on platinum wire, into the flame of a Bunsen burner, communicate to the flame a yellow coloration.

Strontium.—*Solution of ammonium carbonate* produces a white precipitate, insoluble in *solution of ammonium chloride. Solution of ammonium oxalate* produces a white precipitate, insoluble in *acetic acid* but soluble in *hydrochloric acid. Solution of potassium chromate* produces a light-yellow precipitate, soluble in *acetic acid. Solution of calcium sulphate* produces a white precipitate.

Sulphates.—*Solution of barium chloride* produces a white precipitate insoluble in *hydrochloric acid.*

Sulphides.—The official sulphides, hydrosulphides, and sulphurated compounds evolve hydrogen sulphide when boiled with *hydrochloric acid.*

Sulphites.—*Hydrochloric acid* liberates sulphur dioxide, a colourless gas with a pungent small of burning sulphur. *Solution of barium chloride* produces a white precipitate soluble in *hydrochloric acid.* Sulphites decolorise *N/10 solution of iodine.*

Tartrates.—Tartrates become charred when heated. *Solution of calcium, chloride* added in excess to a solution of a neutral tartrate produces, even when cold, a white franular precipitate, soluble in *acetic acid. Solution of silver nitrate* produces a white precipitate, soluble in *solution of ammonia* and in *nitric acid.* The ammoniacal solution, on heating, deposits metallic silver as a mirror on the sides of the test-tube. When to a solution of tartaric acid in *water,* or of a tartrate acidified with *acetic acid,* a drop of *solution of ferrous sulphate,* then a few drops of *solution of hydrogen peroxide,* and finally an excess of *solution of sodium hydroxide* are added, a purple or violet colour is produced.

Tellurium. *See* **Selenium.**

Thiosulphates.—*Hydrochloric acid* produces a yellow precipitate and liberates sulphur dioxide recognisable by its odour. *Solution of barium chloride* produces no precipitate in dilute solutions; on the further addition of *solution of bromine* a white precipitate is produced. Thiosulphates decolorise *N/10 solution of iodine.*

Tin.—Metallic *zinc* placed in a solution of any tin salt acidified with *hydrochloric acid* precipitates the tin in metallic scales or as a grey sponge. The metal separated from the liquid, is soluble, in boiling *hydrochloric acid,* and the solution, which then contains stannous chloride, produces with *T. Sol. of mercuric chloride* a white precipitate which becomes grey if excess of the tin salt is present.

Zinc.—*Solution of Ammonium hydrosulphide* produces in neutral, and *hydrogen sulphide* in alkaline solutions, a white precipitate, soluble in *hydrochloric acid* but insoluble in *acetic acid. Solution of sodium hydroxide* or *solution of ammonia* produces a white precipitate, soluble in excess of either reagent. *Solution of potassium ferrocyanide* produces a white precipitate, insoluble in *diluted hydrochloric acid.*

APPENDIX V. Br.

Quantitative Limit-test For Lead.

(*Br.*)

APPARATUS

(All glass apparatus used must be lead-free.)

Nessler Glasses—Thin, and of lead-free glass. About 150 millilitres long, and of such diameter that the mark indicating a content of 50 millilitres is at the height of 100 millilimetres from the base.

SOLUTIONS AND REAGENTS

The special solutions and reagents for the Quantitative Limit-test for lead are distinguished by the letters "Pb T".

Strong Solution of Lead Pb T.—Dissolve 0.16 gramme of Lead Nitrate in Distilled Water, adding 50 millilitres of Nitric Acid and dilute with Distilled Water to 1000 millilitres. This solution contains 0.001 gramme of lead in 1 millilitre.

Dilute Solution of Lead Pb T. —Dilute 1 millilitre of the Strong Solution of Lead Pb T., measured from a burette, with Distilled Water so that the resulting solution measured 100 millilitres. This solution contains 0.00001 gramme of lead in 1 millilitre.

Solution of Potassium Cyanide Pb T.—Dissolve 10 grammes of Potassium Cyanide in Distilled Water, add 2 millilitres of Solution of Hydrogen Peroxide and make up to 100 millilitres with Distilled Water. This solution after being allowed to stand, when tested by the quantitative limit-test for lead, gives no colour with the Dilute Solution of Lead Pb T.

Solution of Sodium Sulphide Pb T.—Dissolve 10 grammes of Sodium Sulphide in Distilled Water and make up to 100 millilitres with Distilled Water.

MODE OF TESTING (GENERAL)

Br.

Two solutions of the substance under examination are made in hot Distilled Water: (1) The primary solution containing 12 grammes of the substance. (2) The auxiliary solution containing 2 grammes of the substance. Each solution is filtered (if necessary), made alkaline with *solution of ammonia*, and treated with 1 millilitre of the solution of potassium cyanide Pb T. If the colours of the solutions differ much, the difference may be rectified by the cautious addition of a highly diluted solution of burnt sugar. Then, by the method of trial and error (well known in water analysis as "Nesslerizing"), is determined quantity of the dilute solution of lead Pb T. which must be added to the auxiliary solution, in order that there may be equal colorations produced upon the addition of 2 drops of the solution of sodium sulphide Pb T. to both the primary and the auxiliary solution after dilution to the 50 millilitre mark. In these circumstances, each millilitre of the dilute solution of lead Pb T. required corresponds to 1 part per million of lead in the substance examined. The colorations may be viewed by light reflected from a horizontal white tile through the Nessler glasses inclined at an angle to the observer.

Note.—In some cases, 7 or 4 grammes only are used in the primary solution. In these cases each millilitre of the dilute solution of lead Pb T. required will represent 2 or 5 parts per million of lead respectively.

Substance.	Primary Solution of Substance: Grammes employed.	Auxiliary Solution of Substance Grammes employed.	Dilute Solution of Lead Pb T.: Millimetres employed.	Limit of Lead: Parts per Million.

APPENDIX VI. Br.

Quantitative Limit-test for Arsenic.

(*Br.*)

Note.—In the quantitative limit-test for arsenic the amount of arsenic present per million is calculated as arsenious oxide, As_4O_6.

APPARATUS.—A wide-mouthed bottle capable of holding about 120 millilitres and fitted with a rubber cork through which passes a glass tube. The latter, made from ordinary soft glass tubing, has a total length of 200 millimetres and an internal diameter of 5 millimetres (external diameter 7 millimetres) and is open at both ends. The upper end is slightly widened to a diameter of 8 millimetres, while the lower end is drawn out to about 1 millimetre in diameter, and a hole about 2 millimetres in diameter blown in the side of the tube where it is constricted.

LEAD PAPERS.—Lead papers are pieces of thin white filter paper 100 millimetres x 40 millimetres, soaked in *solution of lead acetate* and dried.

MERCURIC CHLORIDE PAPERS.—Mercuric chloride papers are circles of smooth white filter paper 5.5 centimetres in diameter soaked in a saturated aqueous solution of mercuric chloride and dried.

Note.—The mercuric chloride papers should be stored in a stoppered bottle in the dark. Mercuric chloride papers that have been exposed to sunlight afford a lighter-coloured stain when employed in an arsenic test.

REAGENTS (*Br.*)

The special reagents for the quantitative limit-test for arsenic are distinguished by the letters "As T."

Brominated Hydrochloric Acid As T.—Solution of Bromine As T., 1 millilitre; Hydrochloric Acid As T. sufficient to produce 100 millilitres. Mix.

Calcium Hydroxide As T.—10 grammes tested as described under "Calcii Hydras," page 1742, give no visible stain.

Citric Acid As T.—10 grammes tested as described under "Acidum Aceticum," page 1740, give no visible stain.

Hydrochloric Acid As T.—Contains not more than 0.1 part per million of arsenic, as shown by the *Control Test*, and is free from iron.

Nitric Acid As T.—10 millilitres treated as described under "Acidum Nitricum," page 1741, give no visible stain.

Potassium Chlorate As T.—Five grammes tested as described under "Potassii Chloras," page 1744. give no visible stain.

Solution of Arsenic As T.—Hydrochloric Solution of Arsenic, 1 millilitre; Distilled Water sufficient to produce 1000 millilitres. Mix. This solution must be freshly prepared. 1 millilitre contains 0.00001 gramme (one-hundredth of one milligram) of arsenic.

Solution of Bromine As T.—Bromine 30 grammes; Potassium Bromide, 30 grammes; Distilled Water sufficient to produce 100 millilitres. Dissolve. It contains not more than 1 part per million of arsenic as shown by the *Control Test.*

Solution of Stannous Chloride As T.—It is prepared from the Solution of Stannous Chloride, Appendix II, page 1734, by adding an equal volume of Hydrochloric Acid, boiling down to the original bulk and filtering. It contains not more than 1 part per million of arsenic, as shown by the *Control Test.*

Stannated Hydrochloric Acid As T.—Solution of Stannous Chloride As T., 1 millilitre; Hydrochloric Acid As T. sufficient to produce 100 millilitres. Mix.

Sulphuric Acid As T.—Ten grammes, tested as described under "Acidum Sulphuricum," page 1741, but omitting the stannated hydrochloric acid As T. and adding 0.2 millilitre of solution of stannous chloride As T., give no visible stain.

Zinc As T.—Zinc As T. is granulated zinc which conforms to the arsenic requirement involved in the *Control Test*, and is free from iron.

METHOD OF PERFORMING THE QUANTITATIVE TEST FOR ARSENIC

By a variable method of procedure suitable to the particular needs of each case there is prepared from the substance to be tested a solution, which may or may not contain the substance to be treated, but in every case contains the whole of the arsenic (if any) originally in that substance. It is this solution—hereinafter referred to as "the solution to be examined"—which is introduced into the actual test.

General Test.—A strip of lead paper is rolled up and placed in the glass tube so that the upper end is not less than 2 centimetres below the top of the tube. A piece of the mercuric chloride paper is now placed over the top of the tube and secured by means of a rubber ring. The tube is inserted in the rubber cork. The solution to be examined, prepared as specified, is placed in the wide-mouthed bottle and 10 grammes zinc As T. added. The rubber cork with glass tube attached is quickly placed in position so that the lower end of the tube is clear above the surface of the liquid, and the hole is the constricted portion of the tube is clear below the bottom of the cork. The action should be allowed to proceed for thirty to forty minutes the mercuric chloride paper not being exposed to strong sunlight. The yellow stain which is produced on the mercuric chloride paper if arsenic be present is compared, by daylight, with stains produced by operating in a similar manner with known quantities of the solution of arsenic As T. The comparison of the stains should be made at the completion of the test and those used for comparison should be freshly prepared. The stains fade upon keeping.

Note.—The action may be accelarated by standing the apparatus on a hot plate, care being taken that the mercuric chloride paper remains quite dry throughout the duration of the test.

Standard Stain.—Prepare a solution by adding to 50 millilitres of hot *water*, 10 millilitres of stannated hydrochloric acid As T. and 1 millilitre of solution of arsenic As T. The resulting solution when treated as described in the "General Test" will yield a stain on the mercuric chloride paper hereinafter referred to as the "Standard Stain".

CONTROL TESTS FOR REAGENTS AS T.

Hydrochloric Acid As T.—To 50 millilitres of the hydrochloric acid to be tested add 0.2 millilitre of solution of bromine As T., evaporate on a water-bath until reduced to 16 millilitres, add 50 millilitres of hot *water* and 5 drops of solution of stannous chloride As T. and with this solution carry out the "General Test" described above. The stain produced on the mercuric chloride paper is not deeper that that given by 10 millilitres of the same hydrochloric acid with 5 drops of solution of stannous chloride As T., 0.4 millilitre of solution of arsenic As T. and 50 millilitres of hot *water*, showing that the proportion of arsenic present does not exceed 0.1 part per million.

Solution of Bromine As T.—Evaporate 10 millilitres of the solution of bromine on water-bath nearly to dryness, add 50 millilitres of hot *water*, 10 millilitres of hydrochloric acid As T., and sufficient solution of stannous chloride As T. to reduce the remaining bromine, and with this solution carry out the "General Test," described above. The stain produced on the mercuric chloride paper is not deeper than the Standard Stain, showing that the proportion of arsenic present does not exceed 1 part per million.

Solution of Stannous Chloride As T.—To 10 millilitres of the solution of stannous chloride add 6 millilitres of water and 10 millilitres of hydrochloric acid As T., and distill 16 millilitres. To the distillate add 50 millilitres of hot *water* and a few drops of solution of stannous chloride As T. and with this solution carry out the "General Test" described above. The stain produced on the mercuric chloride paper is not deeper than the Standard Stain, showing that the proportion of arsenic present does not exceed 1 part per million.

Zinc As T.—Add 10 millilitres of stannated hydrochloric acid As T., to 50 millilitres of hot *water*, and with this solution of 10 grammes of zinc As T. proceed as with the "General Test," but allow the action to continue for one hour. No visible stain is produced on the mercuric chloride paper (limit of arsenic in the zinc).

The following Table shows the varying methods of preparing the "solution to be examined." The quantities are so arranged that, when tested according to the "General Test" described above, the stain produced on the mercuric chloride paper is not deeper than the Standard Stain, showing that the proportion of arsenic present does not exceed the permissible limit.

Substance.	Solution to be examined.	Limit of Arsenic: Parts per million.
Acidum Aceticum	5 grammes in 50 millilitres of hot *water*, adding 10 millilitres of stannated hydrochloric acid As T.	2
Acidum Acetylsalicylicum	5 grammes made into a paste in a porcelain dish with 2 grammes of calcium hydroxide As T. and 5 millilitres of *water*, drying and gently igniting, dissolving residue in 16 millilitres of brominated hydrochloric acid As T. and 45 millilitres of hot *water*, and finally removing excess of bromine by a few drops of solution of stannous chloride As T.	2
Acidum Benzoicum	5 grammes treated as described under "Acidum Acetylsalicylicum."	2
Acidum Boricum	2 grammes with 4 grammes of citric acid As T. in 50 millilitres of hot *water*, adding 10 millilitres of stannated hydrochloric acid As T.	5

Substance.	Solution to be examined.	Limit of Arsenic: Parts per million.
Acidum Citricum	7 grammes treated as described under "Acidum Aceticum."	1.4
Acidum Hydriodicum Dilutum	2 grammes with 50 millilitres of hot *water*, adding 0.5 millilitre of solution of bromine As T. and 10 millilitres of hydrochloric acid As T., allowing it to stand for five minutes, and removing excess of bromine by a few drops of solution of stannous chloride As T.	5
Acidum Hydrobromicum Dilutum	2 grammes treated as described under "Acidum Aceticum."	5
Acidum Hydrochloricum	2 grammes with 50 millilitres of hot *water* and 8 millilitres of stannated hydrochloric acid As T.	5
Acidum Lacticum	2 grammes treated as described under "Acidum Aceticum."	5
Acidum Nitricum	2 grammes heated in a porcelain dish with 2 millilitres of sulphuric acid As T. until white fumes are evolved then cooling, adding 2 millilitres of *water*, again heating until white fumes are evolved again cooling and adding to the residue 50 millilitres of hot *water* and 10 millilitres of stannated hydrochloric acid As T.	5
Acidum Phosphoricum Concentratum	2 grammes treated as described under "Acidum Aceticum."	5
Acidum Salicylicum	5 grammes treated as described under "Acidum Acetylsalicylicum."	2
Acidum Sulphuricum	2 grammes mixed with 10 millilitres of *water*, adding 40 millilitres of hot *water* and 8 millilitres of stannated hydrochloric acid As T.	5
Acidum Sulphurosum	2 grammes mixed in the cold with 0.5 gramme of potassium chlorate As T. and 11 millilitres of hydrochloric acid As T., warming to expel excess of chlorine, then adding 50 millilitres of hot *water* and a few drops of solution of stannous chloride As T.	5
Acidum Tartaricum	7 grammes treated as described under "Acidum Aceticum."	1.4
Alumen Purificatum	2 grammes treated as described under "Acidum Aceticum."	5
Ammonii Benzoas	5 grammes treated as described under "Acidum Acetylsalicylicem."	2
Ammonii Bromidum	2 grammes in 50 millilitres of hot *water*, adding 12 millilitres of stannated hydrochloric acid As T.	5
Ammonii Carbonas	5 grammes in 50 millilitres of hot *water*, boiled gently until the greater part of the ammonium carbonate is volatilised, then adding 15 millilitres of brominated hydrochloric acid As T. and removing excess of bromine by a few drops of solution of stannous chloride As T.	2
Ammonii Chloridum	2 grammes treated as described under "Acidum Aceticum."	5
Antimonium Sulphuratum	0.01 gramme dissolved by boiling in a small flask with 0.2 gramme of clacium hydroxide As T. and 5 millilitres of *water*, then adding 2 millilitres of solution of bromine As T. and again gently boiling then adding 17 millilitres of hydrochloric acid As T. and 5 millilitres of *water* and boiling until most of the bromine is volatilised, the last traces being removed by adding a slight excess of solution of stannous chloride As T., connecting to a condenser and distilling 20 millilitres, then washing the condenser and flask, returning the distillate to the flask, adding 1 drop of solution of stannous chloride As T. and redistilling 16 millilitres, then adding to the distillate 45 millilitres of hot *water* and a few drops of solution of stannous chloride As T.	1000
Bismuthi Carbonas	5 grammes dissolved in a small flask in 5 millilitres of *water* and 20 millilitres of brominated hydrochloric acid As T., removing excess of bromine by a few drops of solution of stannous chloride As T., connecting to a condenser and distilling 18 millilitres, then adding to the distillate 40 millilitres of hot *water* and 3 drops of solution of stannous chloride As T.	2

Substance.	Solution to be examined.	Limit of Arsenic: Parts per million.
Bismuthi Salicylas	5 grammes made into a paste in a porcelain dish with 1 gramme of calcium hydroxide As T. and 5 millilitres of *water*, drying and gently igniting, dissolving the residue in 20 millilitres of brominated hydrochloric acid As T. and 10 millilitres of *water*, transferring to a small flask and adding sufficient solution of stannous chloride As T. to remove the excess of bromine, connecting to a condenser and distilling 20 millilitres, then adding to the distillate 40 millilitres of hot *water* and 3 drops of solution of stannous chloride As T.	2
Bismuthi Subnitras	5 grammes heated in a porcelain dish with 2 millilitres of sulphuric acid As T. until white fumes are evolved, cooling, adding 5 millilitres of *water* and again heating until white fumes are evolved, dissolving the residue when cold in 20 millilitres of *water* and 10 millilitres of stannated hydrochloric acid As T., transferring to a small flask, connecting to a condenser and distilling 20 millilitres, adding to the distillate a little solution of bromine As T. to oxidise any sulphurous acid, removing excess of bromine by a few drops of solution of stannous chloride As T., and adding 40 millilitres of hot *water*.	2
Borax Purificatus	2 grammes with 4 grammes of citric acid As T. in 50 millilitres of hot *water*, adding 12 millilitres of stannated hydrochloric acid As T.	5
Calcii Carbonas Præcipitatus	2 grammes in 14 millilitres of brominated hydrochloric acid As T. and 45 millilitres of hot *water*, removing excess of bromine by a few drops of solution of stannous chloride As T.	5
Calcii Chloridum	2 grammes treated as described under "Acidum Aceticum."	5
Calcii Hydras	2 grammes in 16 millilitres of brominated hydrochloric acid As T. and 45 millilitres of hot *water*, removing excess of bromine by a few drops of solution of stannous chloride As T.	5
Calcii Hypophosphis	2 grammes mixed in the cold with 2 grammes of potassium chlorate and 18 millilitres of hydrochloric acid As T., then warming to expel excess of chlorine, adding 40 millilitres of hot *water* and a few drops of solution of stannous chloride As T.	5
Calcii Lactas	2 grammes treated as described under "Ammonii Bromidum."	5
Calcii Phosphas	2 grammes in 50 millilitres of hot *water* and 14 millilitres of stannated hydrochloric acid As T.	5
Calx	2 grammes in 18 millilitres of brominated hydrochloric acid As T. and 40 millilitres of *water*, removing excess of bromine by a few drops of solution of stannous chloride As T.	5
Creta Præparata	2 grammes treated as described under "Calcii Carbonas Præcipitatus."	5
Cupri Sulphas	1 gramme dissolved in a small flask, with 10 millilitres of *water* and 15 millilitres of hydrochloric acid As T., adding 5 drops of solution of stannous chloride As T., connecting to a condenser and distilling 20 millilitres, adding a little solution of bromine As T. to the distillate to oxidise any sulphurous acid, removing excess of bromine by a few drops of solution of stannous chloride As T., finally adding 40 millilitres of hot *water*.	10
Ferri Carbonas Saccharatus	2 grammes made into a paste with 1 gramme of calcium hydroxide As T. and 2 millilitres of *water* in a porcelain dish, drying and gently igniting, dissolving the residue in 20 millilitres of brominated hydrochloric acid As T. and 10 millilitres of *water*, transferring to a small flask, adding solution of stannous chloride As T. until the yellow colour disappears, then connecting to a condenser and distilling 24 millilitres, finally adding to the distillate 35 millilitres of hot *water* and 3 drops of solution of stannous chloride As T.	5
Ferri et Ammonii Citras	2 grammes treated as described under "Ferri Carbonas Saccharatus."	5

Substance.	Solution to be examined.	Limit of Arsenic: Parts per million.
Ferri et Potassii Tartras	2 grammes treated as described under "Ferri Carbonas Saccharatus."	5
Ferri et Quininæ Citras	2 grammes treated as described under "Ferri Carbonas Saccharatus."	5
Ferri Phosphas Saccharatus	2 grammes treated as described under "Ferri Carbonas Saccharatus."	5
Ferri Sulphas	5 grammes dissolved in a small flask, with 10 millilitres of *water* and 15 millilitres of hydrochloric acid As T., adding solution of stannous chloride As T. until the yellow colour disappears, connecting to a condenser and distilling 20 millilitres, adding a a little solution of bromine As T. to the distillate to oxidise any sulphurous acid, removing excess of bromine by a few drops of solution of stannous chloride As T., and finally adding 40 millilitres of hot *water*.	2
Ferri Sulphas Exsiccatus	2 grammes treated as described under "Ferri Sulphas."	5
Ferrum	0.05 gramme mixed in a small flask with 0.1 gramme of potassium chlorate As T. and 7 millilitres of *water*, adding 11 millilitres of hydrochloric acid As T. and, when the reaction has ceased and all the iron is dissolved, boiling gently to expel chlorine, then adding solution of stannous chloride As T. until the yellow colour disappears, connecting to a condenser and distilling 14 millilitres, finally adding to the distillate 50 millilitres of hot *water* and a few drops of solution of stannous chloride As T.	200
Ferrum Redactum	0.05 gramme treated as described under "Ferrum."	200
Glucosum	5 grammes treated as described under "Acidum Hydriodicum Dilutum."	2
Glycerinum	2.5 grammes treated as described under "Acidum Aceticum."	4
Liquor Ammoniæ Fortis	20 grammes evaporated on a water-bath until reduced to 5 millilitres, adding 40 millilitres of *water* and 15 millilitres of brominated hydrochloric acid As T., and removing excess of bromine by a few drops of solution of stannous chloride As T.	0.5
Liquor Ferri Perchloridi Fortis	1 gramme heated in a porcelain dish with 1 millilitre of sulphuric acid As T. until white fumes are evolved, cooling, adding an equal volume of *water* and again heating until white fumes are evolved, dissolving the residue in 10 millilitres of water and 15 millilitres of hydrochloric acid As T., transferring to a small flask, adding solution of stannous chloride As T. until the yellow colour disappears, connecting to a condenser and distilling 20 millilitres, adding to the distillate a little solution of bromine As T. to oxidise any sulphurous acid, removing excess of bromine by a few drops of solution of stannous chloride As T. and then adding 40 millilitres of hot *water*.	10
Liquor Ferri Persulphatis	2 grammes treated as described under "Liquor Ferri Perchloridi Fortis."	5
Liquor Magnesii Bicarbonatis	50 millilitres with 13 millilitres of bromated hydrochloric acid As T., removing excess of bromine by a few drops of solution of stannous chloride As T.	0.2
Lithii Carbonas	2 grammes treated as described under "Calcii Hydras."	5
Lithii Citras	5 grammes in 45 millilitres of hot *water*, adding 15 millilitres of stannated hydrochloric acid As T.	2
Magnesia Levis	2 grammes with 40 millilitres of *water* and 20 millilitres of brominated hydrochloric acid As T., removing excess of bromine by a few drops of solution of stannous chloride As T.	5
Magnesia Ponderosa	2 grammes treated as described under "Magnesia Levis."	5

Substance.	Solution to be examined.	Limit of Arsenic: Parts per million.
Magnesii Carbonas Levis	2 grammes in 45 millilitres of hot *water* and 15 millilitres of brominated hydrochloric acid As T., removing excess of bromine by a few drops of solution of stannous chloride As T.	5
Magnesii Carbonas Ponderosus	2 grammes treated as described under "Magnesii Carbonas Levis."	5
Magnesii Sulphas	2 grammes treated as described under "Acidum Aceticum."	5
Potassii Acetas	2 grammes treated as described under "Ammonii Bromidum."	5
Potassii Bicarbonas	2 grammes in 50 millilitres of hot *water*, adding 12 millilitres of brominated hydrochloric acid As T., removing excess of bromine by a few drops of solution of stannous chloride As T.	5
Potassii Bromidum	2 grammes treated as described under "Ammonii Bromidum."	5
Potassii Carbonas	5 grammes in 50 millilitres of hot *water*, adding 16 millilitres of bromated hydrochloric acid As T., removing excess of bromine by a few drops of solution of stannous chloride As T.	2
Potassii Chloras	2 grammes mixed in the cold with 10 millilitres of *water* and 20 millilitres of hydrochloric acid As T. and, when the reaction is complete, warming to expel chlorine, then adding a few drops of solution of stannous chloride As T. and 30 millilitres of hot *water*.	5
Potassii Citras	5 grammes treated as described under "Lithii Citras."	2
Potassii Iodidum	2 grammes treated as described under "Ammonii Bromidum."	5
Potassii Nitras	2 grammes heated in a porcelain dish with 2 millilitres of sulphuric acid As T. and 5 millilitres of *water* until white fumes are evolved, cooling, adding 3 millilitres of *water* and again heating until white fumes are evolved, finally cooling and adding to the residue 50 millilitres of hot *water* and 10 millilitres of stannated hydrochloric acid As T.	5
Potassii Sulphas	2 grammes treated as described under "Acidum Aceticum."	5
Potassii Tartras	5 grammes treated as described under "Calcii Phosphas."	2
Potassii Tartras Acidus	5 grammes in 50 millilitres of hot *water* and 13 millilitres of brominated hydrochloric acid As T., removing excess of bromine by a few drops of solution of stannous chloride As T.	2
Sodii Benzoas	5 grammes gently heated in a porcelain dish, until inflammable vapours cease to be evolved, dissolving the residue (ignoring any carbon) in 14 millilitres of brominated hydrochloric acid As T. and 50 millilitres of hot *water* and removing excess of bromine by a few drops of solution of stannous chloride As T.	2
Sodii Bicarbonas	5 grammes treated as described under "Potassii Carbonas."	2
Sodii Bromidum	2 grammes treated as described under "Ammonii Bromidum."	5
Sodii Carbonas	5 grammes in 50 millilitres of hot *water*, adding 14 millilitres of brominated hydrochloric acid As T. and removing excess of bromine by a few drops of solution of stannous chloride As T.	2
Sodii Carbonas Exsiccatus	2 grammes treated as described under "Sodii Carbonas."	5
Sodii Chloridum	5 grammes treated as described under "Acidum Aceticum."	2
Sodii et Potassii Tartras	5 grammes treated as described under "Calcii Phosphas."	2
Sodii Hypophosphis	2 grammes treated as described under "Calcii Hypophosphis."	5
Sodii Iodidum	2 grammes in 50 millilitres of hot *water*, adding 11 millilitres of stannated hydrochloric acid As T.	5
Sodii Nitris	2 grammes treated as described under "Potassii Nitras."	5

Substance.	Solution to be examined.	Limit of Arsenic: Parts per million.
Sodii Phosphas	2 grammes treated as described under "Acidum Aceticum."	5
Sodii Phosphas Acidus	5 grammes treated as described under "Acidum Aceticum."	2
Sodii Salicylas	5 grammes treated as described under "Sodii Benzoas."	2
Sodii Sulphas	5 grammes treated as described under "Acidum Aceticum."	2
Sodii Sulphis	2 grammes with 0.5 gramme of potassium chlorate As T. in 5 millilitres of warm *water*, adding 12 millilitres of hydrochloric acid, As T. then warming to expel excess of chlorine and adding 45 millilitres of hot *water* and a few drops of solution of stannous chloride As T.	5
Strontii Bromidum	2 grammes treated as described under "Ammonii Bromidum."	5
Sulphur Præcipitatum	2 grammes digested for one hour on a water bath with 50 millilitres of *water* and 5 millilitres of solution of ammonia, filtering and evaporating the filtrate to low bulk, adding 10 millilitres of nitric acid As T. and boiling to oxidise any sulphur then adding 2 millilitres of sulphuric acid As T. and heating until white fumes are evolved, cooling, adding 2 millilitres of *water*, and again heating until white fumes are evolved, finally adding 50 millilitres of hot *water* and 10 millilitres of stannated hydrochloric acid As T.	
Sulphur Sublimatum	2 grammes treated as described under "Sulphur Præcipitatum."	5
Zinci Acetas	2 grammes treated as described under "Ammonii Bromidum."	5
Zinci Carbonas	1 gramme treated as described under "Potassii Carbonas."	10
Zinci Chloridum	2 grammes treated as described under "Acidum Aceticum."	5
Zinci Oxidum	1 gramme treated as described under "Potassii Carbonas."	10
Zinci Sulphas	2 grammes treated as described under "Acidum Aceticum."	5
Zinci Valerianas	2 grammes made into a paste in a porcelain dish with 2 grammes of calcium hydroxide As T. and 5 millilitres of *water*, drying and gently igniting, then dissolving the residue in 18 millilitres of brominated hydrochloric acid As T. and 40 millilitres of hot *water* and removing excess of bromine by a few drops of solution of stannous chloride As T.	5

APPENDIX VII. Br.

Determination of the Acid Value of Fixed Oils, Fats, Waxes, and Resins.

(*Br.*)

The acid value of a fixed oil, fat, or wax (the number of milligrams of potassium hydroxide required to neutralize the free acid in 1 gramme of the substance) is determined as follows:—Mix 10 grammes of the substance with 50 millilitres of *alcohol* (90 per cent.), previously neutralised with *solution of potassium hydroxide*, add 1 millilitre of *solution of phenolphthalein*, heat until the fat or wax is melted and titrate with *N/10 solution of potassium hydroxide*, shaking constantly. Note the number of millilitres required (*a*). Calculate the acid value from the following formula:—

$$\textbf{Acid value} = \frac{a \times 0.0056 \times 1000}{\text{weight (in grammes) of substance taken}}$$

The acid value of a resin is determined by dissolving from 1 to 5 grammes of the substance in 50 millilitres of *alcohol* (90 per cent.), previously neutralized, and titrating and calculating as above directed.

Determination of the Saponification Value of Fixed Oils, Fats, Waxes, and Resins.

(*Br.*)

The saponification value of a fixed oil, fat, wax, or resin (the number of milligrams of potassium hydroxide required for the complete saponification of 1 gramme of the substance) is determined as follows:—Dissolve 40 grammes of *potassium hydroxide* in 1000 millilitres of *alcohol* (90 per cent.), previously neutralised; allow the solution to stand for twenty-four hours and filter. Weigh from 1.5 to 2 grammes of the substance in a flask having a capacity of about 200 millilitres; add 25 millilitres of the alcoholic solution of potassium hydroxide, attach a reflex condenser and heat on a water-bath for thirty minutes: add 1 millilitre of *solution of phenolphthalein* and titrate the excess of alkali with *N/2 solution of hydrochloric acid.* Note the number of millilitres required (*a*). At the same time treat 25 millilitres of the alcoholic solution of potassium hydroxide in a similar manner. Note the number of millilitres required (*b*). Calculate the saponification value from the following formula:—

$$\textbf{Saponification value} = \frac{(b-a) \times 0.028 \times 1000}{\text{weight (in grammes) of substance taken}}$$

Determination of the Iodine Value of Fixed Oils and Fats.

(*Br.*)

The iodine value of a fixed oil or fat (the proportional weight of iodine absorbed by 100 parts by weight of the oil or fat under the conditions specified) is determined as follows:—

Solution to be Prepared.—Iodine Solution.—Dissolve 13 grammes of iodine in 1000 millilitres of *glacial acetic acid.* Titrate the solution with *N/10 solution of sodium thiosulphate,* note the proportion required and pass *chlorine,* washed and dried, through the remainder of the iodine solution until this proportion is exactly doubled. Keep the solution in a stoppered amber bottle in a cool, dark place.

Weight of Substance to be Taken.—Lard, Suet, and Oil of Theobroma 0.8 to 1.0 gramme; Almond Oil, Castor Oil, and Olive Oil, 0.3 to 0.4 gramme; Cod-liver Oil, and Linseed Oil, 0.15 to 0.18 gramme.

Time to be Allowed for Absorption.—Lard, Suet, and Oil of Theobroma, Almond Oil, Castor Oil, and Olive Oil, 1 hour; Cod-liver Oil and Linseed Oil, 2 hours.

Method of Procedure.—Place the specified weight of oil or fat in a stoppered bottle having a capacity of 800 millilitres, add 10 millilitres of *carbon tetrachloride* and dissolve. Add 25 millilitres of the iodine solution, insert the stopper, previously moistened with *solution of potassium iodide,* and keep in a dark place at a temperature of about 17° for the specified time. Then add 20 millilitres of *solution of potassium iodide* and 500 millilitres of *water.* Shake, and titrate with *N/10 solution of sodium thiosulphate,* using *mucilage of starch* as indicator. Note the number of millilitres required (*a*). At the same time treat 25 millilitres of the solution of iodine in a similar manner and note the number of millilitres of *N/10 solution of sodium thiosulphate* required (*b*). Calculate the iodine value from the following formula:—

$$\textbf{Iodine value} = \frac{(b-a) \times 0.01269 \times 100}{\text{weight (in grammes) of oil or fat taken}}$$

Determination of the Unsaponifiable Matter in Fixed Oils and Fats.

(*Br.*)

The percentage of unsaponifiable matter in a fixed oil or fat is determined as follows:—Boil 5 grammes of the oil or fat with 50 millilitres of *N/1 alcoholic solution of potassium hydroxide* in a flask provided with a reflux condenser on a water-bath for thirty minutes. Transfer the contents of the flask to a porcelain dish and evaporate the alcohol on a water-bath. Dissolve the resulting soap in about 100 millilitres of hot water, cool and transfer to a separator. Add 50 millilitres of *ether,* mix thoroughly and allow to separate. Transfer the soap solution to another separator and again extract with 50 millilitres of *ether.* Mix the ethereal solutions, wash with three portions each of 20 millilitres, of *water,* transfer to a tared flask, evaporate the ether, dry the residue at 100° C. (212° F.) and weigh. The weight (in grammes) of the residue multiplied by 20 gives the percentage of unsaponifiable matter.

Determination of the Esters in Volatile Oils.

(*Br.*)

The percentage of esters present in a volatile oil is determined as follows:—Dissolve from 2 to 5 grammes of the oil in 25 millilitres of alcohol (90 per cent.) and neutralize the solution, if necessary, with *N/1 alcoholic solution of potassium hydroxide.* Then add 25 millilitres of *N/1 alcoholic solution of potassium hydroxide,* boil in a flask provided with a reflux condenser on a water-bath for one hour and titrate the excess of alkali with *N/1 solution of sulphuric acid.* Note the number of millilitres required (*a*). At the same time treat 25 millilitres of *alcohol* (90 per cent.) in a similar manner and note the number of millilitres of acid required (*b*). Calculate the percentage of esters in the oil from the following formula:—

$$\textbf{Percentage of Esters} = \frac{(b-a) \times \text{molecule weight of esters}}{\text{weight (in grammes) of oil taken} \times 10}$$

Determination of the Alcohols in Volatile Oils.

(*Br.*)

The percentage of alcohols present in a volatile oil is determined as follows:—Heat 10 millilitres of the oil with 10 millilitres of *acetic anhydride* and 2 grammes of *anhydrous sodium acetate* in an acetylation flask for two hours; add 100 millilitres of *water,* transfer to a separator and, after separation, remove the aqueous layer and wash the oily layer free from acidity with successive quantities, each of 100 millilitres of *water,* thoroughly shaking and allowing to separate each time. Dry the acetylated oil with *anhydrous sodium sulphate* and filter. Then treat from 2 to 5 grammes of the acetylated oil according to the process for the determinations of the esters present in volatile oils. Calculate the percentage of alcohols present in the oil from the following formula:—

$$\textbf{Percentage of alcohols} = \frac{\frac{1}{10} \times (b-a) \times \text{molecule weight of the alcohol}}{\text{weight (in grammes) of acetylated oil taken—0.042 } (b-a)}$$

Alkaloidal Assays: Limit of Error.

(*Br.*)

Successive assays of the same substance may yield numerical results varying within narrow limits, which are taken to be the range of "error". When an average of successive assays shows a deviation from the prescribed standard greater or less than the "limit of error," the preparation examined does not conform to the requirements of the British Pharmacopœia.

APPENDIX VIII. Br.

Determination of Melting Points.

(*Br.*)

Prepare some thin-walled glass tubes having an internal diameter of about one millilitre by heating thick-walled, soft glass tubing in a blow-pipe flame, drawing out the heated portion until it has the required diameter, then allowing a small flame to play against the middle of this tube so as to make and seal two tubes which are finally to be cut off to suitable lengths; these tubes should be freshly made; if stored they should be carefully protected from moisture.

Dry a very small quantity of the powdered substance at 100° C. (212° F.) for fifteen minutes; transfer a portion to one of these tubes, shaking the powder down to the sealed extremity. Attach the tube to a thermometer so that the substance is near the middle of the bulb. Heat a suitable liquid, such as *sulphuric acid*, to which *nitric acid* in the proportion of about 4 drops to 100 millilitres has been added, in a beaker or boiling tube about 3 centimetres in diameter, to about 5° below the expected melting point of the substance; this point if not known, being determined by a preliminary experiment. Then introduce the thermometer with the attached tube, and slowly heat, efficiently stirring, and note the temperature at which the substance first shows visible change; this temperature is regarded as the uncorrected melting point of the substance. The whole of the mercury column of the thermometer should be immersed in the liquid, but as this is seldom practicable the following correction is to be applied:—

To the thermometer attach a second thermometer in such a position that its bulb is near the middle of the emergent column of mercury, and observe thereby the mean temperature of the column. Calculate the corrected melting point of the substance from the following formula:—

Corrected melting point $= T + 0.000143$ (T-t N, in which $T =$ the uncorrected melting point; $t =$ the mean temperature of the emergent column; $N =$ the number of scale degrees in the emergent column.

The melting point of solid fats, fatty acids and waxes is determined by running a small quantity of the melted substance into an unsealed melting point tube, allowing it to cool for twenty-four hours, and then, using *water* in the place of sulphuric acid, determining in the manner described the temperature at which the substance becomes a clear liquid; this temperature is to be taken as the uncorrected melting point.

Determination of Boiling Points.

(*Br.*)

Place the liquid under examination in a distillation flask having a side tube for conveying the vapour to a condenser, while a thermometer passes through a cork inserted in the neck. The bulb of the thermometer should be opposite the entrance of the side tube, and not immersed in the liquid or exposed to splashes of it, and the whole of the column of mercury should, if possible, be surrounded by the vapour; the temperature is read off as soon as the liquid is distilling freely. If any considerable length of the column of mercury is not surrounded by the vapour, the mean temperature of the emergent column should be ascertained as directed under the "Determination of Melting Points," and the like correction applied.

Determination of Refractive Indices.

(*Br.*)

The refractive index of a substance should be determined in a suitable apparatus as nearly as possible at the temperature specified. Should the temperature be either above or below the specified temperature, the following correction is to be applied:—For each degree below the specified temperature subtract 0.00038 from the observed refractive index; for each degree above the specified temperature add 0.00038.

Determination of Optical Rotation.

(*Br.*)

The optical rotation unless otherwise specified, is the angle through which the plane of polarisation is turned when a layer of the liquid substance one decimetre in thickness and at a temperature of 20° C is examined by polarised sodium light.

The specific rotation of a substance in solution may be calculated from the formula $\frac{a \times 100}{l \times c}$, where a is the observed optical rotation, l the thickness in decimetres of the layer examined, and c the number of grammes of substance contained in 100 millilitres of the solution.

Determination of Specific Gravity.

(*Br.*)

The specific gravity of a substance is the weight of a given volume of that substance at 15.5° C. (59.9° F.) as compared with the weight of an equal volume of distilled water, at the same temperature unless otherwise specified.

APPENDIX IX. Br.

Process of Percolation.

(*Br.*)

Moisten the solid materials with the prescribed quantity of menstruum, set aside for four hours in a well-closed vessel, pack in a percolator and add sufficient of the menstruum to saturate the materials and leave a layer of liquid above. Macerate for twenty-four hours; then allow percolation to proceed slowly until the percolate measures about three-fourths of the volume required for the finished tincture. Press the marc, mix the expressed liquid with the percolate, and add sufficient of the menstruum to produce the required volume. Clarify by subsidence or filtration, if necessary.

Process of Repercolation.

(*Br.*)

Take one hundred parts by weight of the drug and divide it into five equal portions. Moisten the first portion with the menstruum, set aside in a closed vessel for four hours and pack in a percolator. Add sufficient of the menstruum to saturate the drug and leave a layer of liquid above. Macerate for twenty-four hours, then allow percolation to proceed slowly, collecting the percolate in fractions of twenty parts.

Moisten the second portion of the drug with the first fraction of the percolate collected. Set aside, pack in a percolator, macerate and percolate, as before, using as menstruum the successive fractions of percolate collected from the portion first treated. Again collect the percolate in fractions of twenty parts.

In turn, treat in the manner described above the third, fourth, and fifth portions of the drug with the fractions of percolate obtained in the percolation of the portion immediately preceding using the successive fractions of percolate in order, until a liquid extract is obtained of the required strength.

Process of Maceration.

Place the solid materials with the whole of the menstruum in a closed vessel; shake occasionally during seven days; strain; press the marc; mix the liquids obtained. Clarify by subsidence or filtration if necessary.

APPENDIX X. Br.

Process for Preparation of Discs (Lamellæ).

(*Br.*)

Discs are prepared by the following process:—Gelatin, 18 grammes; Glycerin, 2 grammes; Distilled Water, 88 grammes. Mix the Glycerin with the Distilled Water, allow the Gelatin to soak in the mixture till soft, and then dissolve by a gentle heat; cool the basis so produced. Take the prescribed quantity of the above basis, melt it by a gentle heat, add the prescribed quantity of medicament, dissolve and mix. Pour the melted and medicated basis upon a sheet of plate glass 10 centimetres square, previously thinly coated with White Beeswax, in such a manner that the solution is evenly distributed. Dry at a temperature not exceeding 36° C. (96.8° F.), and from the film thus obtained cut discs 3 millimetres nearly (⅛ inch) in diameter.

APPENDIX XI. Br.

Processes for Preparation of Lozenges (Trochisci).

(*Br.*)

With Fruit Basis.—Take five hundred times the quantity of the drug ordered for one lozenge. Mix with it 6.5 grammes of Tragacanth and 26 grammes of Refined Sugar, both in fine powder. Add sufficient of the black-currant paste of commerce to produce 650 grammes, beat into a uniform mass, divide into 500 equal lozenges and dry in a hot air chamber at a moderate temperature.

With Rose Basis.—Take five hundred times the quantity of the drug ordered for one lozenge. Treat it as described under "Preparation with Simple Basis," previously mixing with the Refined Sugar 0.025 millilitre of oil of Rose.

With Simple Basis.—Take five hundred times the quantity of the drug ordered for one lozenge, mix it with 496 grammes of Refined Sugar and 19.5 grammes of Gum Acacia, both in fine powder. Make the mixture into a paste with 35 millilitres of Mucilage of Gum Acacia and a sufficient quantity of Distilled Water, divide into 500 equal lozenges and dry in a hot air chamber at a moderate temperature.

With Tolu Basis.—Take five hundred times the quantity of the drug ordered for one lozenge; dissolve such salts of alkaloids as may be ordered in 10 millilitres of Distilled Water; mix the solution with 482 grammes of Refined Suger and 19.5 grammes of Gum Acacia, both in fine powder. Incorporate 10 millilitres of Tincture of Balsam of Tolu, and any other drugs ordered for the lozenges. Make into a paste with 35.5 millilitres of Mucilage of Gum Acacia and a sufficient quantity of Distilled Water; divide into 500 equal lozenges and dry in a hot-air chamber at a moderate temperature.

APPENDIX XII. Br.

Alternative Preparations Sanctioned for Use in Tropical, Subtropical, and Other Parts of the British Empire.

(*Br.*)

Aquæ Olei Anethi, Anisi, Carui, Cinnamomi, Fœniculi, Menthæ Piperitæ, Menthæ Viridis.—Each of these Waters may be prepared by tirturating the corresponding Oil with twice its weight of Calcium Phosphate and five hundred times its volume of Distilled Water and filtering the mixture. In tropical and subtropical parts of the Empire these Aquæ Olei may be used in place of the corresponding Aquæ of the Text of the Pharmacopœia.

Emplastra.—In tropical and subtropical parts of the Empire, more or less Hard Soap, Resin, or Yellow Beeswax, may be employed in the preparation of the Plasters of the Text of the Pharmacopœia, when prevailing high temperatures otherwise render the basis too soft for convenient use; but the official proportion of the active ingredient must in all cases be maintained.

Extracta Liquida.—Any Liquid Extract, defined in the Text of the Pharmacopœia, containing less than one-fourth of its weight of Alcohol (90 per cent.), may have the proportion of Alcohol (90 per cent.) increased to an amount not exceeding one-fourth of the weight of the Extract in tropical and subtropical parts of the Empire where otherwise the preparation would be liable to ferment.

Limonis Cortex Siccatus—In tropical and subtropical parts of the Empire, when fresh Lemon Peel cannot be obtained, Dried Lemon Peel may be used in preparing Compound Infusion of Orange Peel, Compound Infusion of Gentian, Syrup of Lemon, and Tincture of Lemon.

Oleum Olivæ.—In India, and in the Eastern, African, Australasian, and North American Divisions of the Empire, Arachis Oil or Sesame Oil, but no other oil or fat, may be employed in making the official Liniments, Plasters, Ointments, and Soaps for which Olive Oil is directed to be used.

Suppositoria.—More or less White Beeswax, according to prevailing temperatures, may be used in place of an equivalent amount of Oil of Theobroma in tropical and subtropical parts of the Empire, when otherwise the Suppositories of the Text of the Pharmacopœia would be too soft for convenient use.

Syrupus Rhœados.—In tropical and subtropical parts of the Empire, when prevailing high temperatures render this preparation liable to ferment, the proportion of Alcohol (90 per cent.) may be increased, but not to more than double the proportion stated in the Text of the Pharmacopœia and equivalent quantity of Distilled Water being omitted.

Unguenta.—In tropical and subtropical parts of the Empire or more less Benzoated Lard, Prepared Lard, Benzoated Suet, Prepared Suet, Yellow Beeswax, or White Beeswax, may be employed in the preparation of the Ointments of the Text of the Pharmacopœia when prevailing high temperatures otherwise render the basis too soft for convenient use; but the official proportion of the active ingredient must in all cases be maintained.

APPENDIX XIII. Br.

Table of Proportions Relating to the Preparation of Diluted Alcohols.

(Br.)

Volume of Alcohol (90 per cent.) to be diluted with Distilled Water to 1000 millilitres at 15.5° C. (59.9° F.) in order to give the Diluted Alcohols of the British Pharmacopœia.

Alcohol Required.	Specific Gravity.	Volume of Alcohol (90 per cent.)
70 per cent.	0.8899	777.8 millilitres
60 per cent.	0.9134	666.7 millilitres
45 per cent.	0.9435	500.0 millilitres
20 per cent.	0.9760	222.2 millilitres

Diagnostic Reagents and Chemical Tests.

(Not Official)

In the following pages of Diagnostical Reagents and Clinical Tests it is understood that the standard for official substances like Iodine, Potassium Iodide, Gelatin, Sodium Chloride, etc., are those of the U. S. P. Where other substances not so described are used, a description will be found elsewhere in this volume.

REAGENTS FOR EXAMINATION OF URINE.

For Acetone.—*Lange's Test. Le Noble's Test. Legal's Test.*

Sodium Nitroprusside (see Sodium Nitroferrocyanide) one part in 20 of distilled water. Must be freshly prepared.

Lieben's Iodine Potassium Iodide Solution:

Potassium Iodide	6 Gm.
Iodine	4 Gm.
Distilled Water, a sufficient quantity, to make	100 cc.

Dissolve the potassium iodide in the distilled water, add the iodine and shake the mixture frequently until a solution is obtained.

Gunning's Test.—Use a freshly prepared 10 per cent. solution of iodine in aclohol.

For Albumin.—*Glacial Acetic Test* (U. S. P.), *Acetic Acid* (U. S. P.), *Trichloracetic Acid* (U. S. P.) and *Nitric Acid* (U. S. P.) are used for various tests.

Esbach's Reagent:

Trinitrophenol	1 Gm.
Citric Acid	2 Gm.
Distilled water, a sufficient quantity	
To make a solution measuring	100 cc.

Spiegler-Jolles' Reagent:

Corrosive Mercuric Chloride	2 Gm.
Succinic Acid	4 Gm.
Sodium Chloride	4 Gm.
Distilled Water, a sufficient quantity	
To make	100 cc.

Mix the several ingredients and dissolve them in the distilled water.

For Albumose.—*Salkowski's Test.* Use a 4 per cent. aqueous solution of phospho-tungstic acid.

UNIVERSITY OF ILLINOIS
LIBRARY CHEMISTRY

For Bile Reactions.—*Urobilin.*
Amyl Alcohol (see page 000).
Solution of Zinc Chloride (10 per cent. in distilled water).
Mixture of Zinc Acetate:

Zinc Acetate	10 Gm.
Dehydrated Alcohol, a sufficient quantity	
To make	100 cc.

Finely powder the zinc acetate and intimately mix with the alcohol. Dispense the mixture with directions "to be well shaken before using."

Urobilinogen.—*Ehrlich's Solution:*

Paradimethylamidobenzaldehyde	2 Gm.
Hydrochloric Acid	50 cc.
Distilled Water, a sufficient quantity	
To make a solution measuring	100 cc.

Biliary Color Reactions.—*Nitric Acid* (containing a trace of nitrous acid). This may be prepared by adding a few drops of formaldehyde to nitric acid.

Hupert's Test.—Use a 10 per cent. aqueous solution of calcium chloride.

Alcoholic Solution of Iodine (about 1 per cent.):

Iodine	1 Gm.
Alcohol, a sufficient quantity	
To make a solution measuring	100 cc.

For Blood Reaction.—*Benzidine Hydrochloride.* A freshly prepared saturated solution of benzidine hydrochloride in glacial acetic acid.

Solution of Guaiac.—A 2 per cent. solution of guaiac in dehydrated alcohol.

Ether and Solution of Hydrogen Dioxide of full strength are used in the benzidine test.

For Diacetic Acid Reaction.—*Gerhardt's Test.* A 2 per cent. freshly prepared aqueous solution of ferric chloride.

For Diazo Reaction, Ehrlich:

1. Sodium Nitrite	1 Gm.
Distilled Water, a sufficient quantity	
To make	200 cc.
2. Sulphanilic Acid	5 Gm.
Hydrochloric Acid	50 cc.
Distilled Water, a sufficient quantity	
To make	1000 cc.

Dissolve the sulphanilic acid in about 700 cc. of distilled water to which the hydrochloric acid has been added and follow with enough distilled water to make the product measure 1000 cc.

For use, 1 cc. of the sodium nitrite solution should be mixed with 50 cc. of the sulphanilic acid solution.

For Indican Reaction.—*Solution of Chlorinated Lime.* A saturated solution of chlorinated lime diluted with an equal volume of distilled water and filtered.

Obermeyer's Solution:

Ferric Chloride	0.4 Gm.
Hydrochloric Acid, U. S. P., a sufficient quantity	
To make a solution measuring	100 cc.

Solution of Lead Acetate.—A 25 per cent. filtered, aqueous solution.

For Pentose Reactions.—*Bial's Reagent:*

Orcin	1 Gm.
Hydrochloric Acid	500 cc.
Solution of Ferric Chloride	25 drops

Dissolve the orcin in the hydrochloric acid and add the solution of ferric chloride.

Phloroglucinol T.S.—A 3 per cent. alcoholic solution.

For the Estimation of Urea.—*Solution of Sodium Hypobromite:*

1. Bromine	125 Gm.
Sodium Bromide	125 Gm.
Distilled Water, a sufficient quantity	
To make a solution measuring	1000 cc.
2. Sodium Hydroxide	225 Gm.
Distilled Water, a sufficient quantity	
To make a solution measuring	1000 cc.

The reagent should be freshly prepared by mixing equal volumes of solutions 1 to 2 and diluting the resulting mixture with one and a half volumes of distilled water.

For Sugar Reactions.—*Solution of Sodium Hydroxide.* A 10 per cent. aqueous solution of sodium hydroxide.

Solution of Copper Sulphate.—A 10 per cent. aqueous solution of uneffloresced crystals of copper sulphate.

Nylander's Reagent:

Potassium and Sodium Tartrate	4 Gm.
Sodium Hydroxide	10 Gm.
Bismuth Subnitrate	2 Gm.
Distilled Water, a sufficient quantity	
To make	100 cc.

Dissolve the potassium and sodium tartrate in 90 cc. of distilled water. Add the bismuth subnitrate to the solution, shake the mixture thoroughly and then filter through glass wool. Preserve and dispense this solution in amber-colored bottles.

Benedict's Solution:(Qualitative)

Sodium (or potassium) Citrate	173	Gm.
Sodium Carbonate, Anhydrous	100	Gm.
Distilled Water	700	cc.

Dissolve with the aid of heat.

Copper Sulphate Crystals	17.3	Gm.
Distilled Water	100	cc.

Dissolve with the aid of heat.

Cool both solutions to room temperature, pour the copper solution into the other slowly and with constant stirring, and make up to 1000 cc. with distilled water.

Benedict's Solution: (Quantitative)

Copper Sulphate (Cryst)	18 Gm.
Sodium Carbonate (Cryst) (½ the weight of the anhydrous salt may be used)	200 Gm.
Potassium Sulphocyanate	125 Gm.
Sodium Citrate	200 Gm.
Potassium Ferrocyanide, 5 per cent. solution	5 cc.
Distilled Water to measure	1000 cc.

With the aid of heat dissolve the citrate, carbonate and sulphocyanate in enough water to make about 800 cc. of the mixture, and filter. Dissolve the copper sulphate in about 100 cc. of water and pour the solution slowly into the other liquid with constant stirring. Add the ferrocyanide solution cool, and dilute to exactly one litre. Of the various constituents, only the copper need to be *weighed with exactness.* 25 cc. of the reagent are reduced by 0.050 Gms. of glucose, or by 0.055 Gms. of levulose.

Fehling's Solution: (See Alkaline Cuptric Tartrate V.S.)

Pavy's Solution:

1.	Copper Sulphate	4.158 Gm.
	Distilled Water, a sufficient quantity	
	To make a solution measuring	500 cc.
2.	Potassium and Sodium Tartrate	20.4 Gm.
	Potassium Hydroxide	20.4 Gm.
	Stronger Ammonia Water	300.0 cc.
	Distilled Water, a sufficient quantity	
	To make a solution measuring	500.0 cc.

For use, mix equal quantities of the two solutions.

REAGENTS FOR THE EXAMINATION OF KIDNEY FUNCTION.

Phenolsulphonphthalein.—An aqueous solution containing in each cc. 6 mgm. of the dye in the form of a mono-sodium salt. (See *Phenol Sulphonphthaleinum,* Part I.)

Indigo-Carmine Reagent.—An aqueous solution containing 10 per cent. of sodium indigotindisulphonate (U.S.). (See Part I.)

REAGENTS FOR THE EXAMINATION OF GASTRIC CONTENTS.

Congo Red Test Paper.—Saturate filter paper with an aqueous solution of Congo Red (1 in 1000). Dry and cut the paper into strips and preserve them in well-stoppered glass vials.

Topfer's Reagent.—*(Alcoholic Solution of Dimethylaminoazobenzene.)* Dissolve 5 Gm. of the dye in 100 cc. of alcohol.

Gunzburg's Reagent:

Phloroglucinol	2 Gm.
Vanillin	1 Gm.
Alcohol	30 cc.

Dissolve the ingredients in the alcohol.

REAGENTS FOR THE EXAMINATION OF BLOOD.

For Red Blood Corpuscles.—*Hayem's Solution:*

Sodium Sulphate	5	Gm.
Sodium Chloride	1	Gm.
Corrosive Mercuric Chloride	0.5	Gm.
Distilled Water	200	cc.

Dissolve the salts in the distilled water and filter.

Toisson's Solution:

Methyl Violet 6B	0.025 Gm.
Sodium Chloride	1.000 Gm.
Sodium Sulphate	8.000 Gm.
Glycerin (Neutral)	30.000 cc.
Distilled water	300.000 cc.

Dissolve the salts in the distilled water and add the methyl violet and the glycerin.

For White Corpuscles:

Acetic Acid (U. S. P.)	1 cc.
Distilled Water	99 cc.

Mix them.

Jenner's Stain:

1. Eosin	0.5 Gm.
Methanol, a sufficient quantity	
To make a solution measuring	100 cc.
2. Methylene Blue	0.5 Gm.
Methanol, a sufficient quantity to make a solution measuring	100 cc.

For use mix 25 cc. of eosin solution with 20 cc. of methylene blue solution.

Ehrlich's Triacid Stain:

Saturated Aqueous Solution of Orange-G	120–125 cc.
Satruated Aqueous Solution of Acid Fuchsin	80 –165 cc.
Saturated Aqueous Solution of Methylene Green	125 cc.
Distilled Water	300 cc.
Dehydrated Alcohol	200 cc.
Glycerin	100 cc.

Mix.

Wright's Stain:

Wright's Stain (dried powder)	0.1 Gm.
Methanol (Rectified)	60.0 cc.

Giemsa's Stain:

Azur II–Eosin	0.3 Gm.
Azur II	0.8 Gm.
Glycerin	250.0 cc.
Methanol (Rectified)	250.0 cc.

Dissolve the dyes in the methanol and add the glycerin and filter.

STAINS FOR USE IN THE STUDY OF MICRO-ORGANISMS.

The amounts of distilled water and absolute alcohol respectively required to produce saturated solutions of the common stains are indicated in the following table:

	Gram of Dye	Water cc.	Alcohol cc.
Bismarck Brown, pure	1	70	70
Fuchsine (Basic)	1	100	25
Gentian violet	1	70	70
Hematoxylin	1	20	10
Methyl violet	1	50	10
Methylene blue	1	70	70
Thionin blue	1	50	100

Alum-hematoxylin Solution:

Hematoxylin, crystals	1.0 Gm.
Saturated Aqueous Solution of Ammonium Alum	100.0 cc.
Distilled Water	300.0 cc.
Thymol	0.5 Gm.

Dissolve the hematoxylin in a little distilled water by the aid of heat, add the other ingredients and expose the combined solution to the light, in a bottle loosely stoppered, until it has assumed a dark red colour, then filter. The thymol is added as a preservative.

Hematoxylin Solution (Delafield):

Hematoxylin crystals	1.0 Gm.
Alcohol	6.0 cc.

To this solution add

Saturated aqueous solutions of ammonium alum	100 cc.

Expose to light for one week, when the colour will change to a deep purple.

Add to this ripened stain

Glycerin	25 cc.
Methanol	25 cc.

Let stand 2 days and filter.

This makes a stock solution which should be diluted with 10 parts of water when staining.

Mayer's Hemalum:

Hematein or its ammonium salt	1.0 Gm.
Alcohol, 90 per cent	50.0 cc.
Alum	50.0 Gm.
Distilled Water	1000.0 cc.
Thymol	0.5 Gm.

Dissolve the hematein in the alcohol by the aid of heat, add the thymol, and then this solution to the alum dissolved in the distilled water, and then filter. The thymol is added as a preservative.

Alcoholic Solution of Eosin:

Eosin, S. F. Yellowish	0.5 Gm.
Alcohol diluted	100 cc.

Alcoholic Solution of Methyl Violet 6B:

Methyl Violet 6B	10 Gm.
Alcohol, a sufficient quantity	
To make a solution measuring	100 cc.

Borax-Methylene Blue Solution:

Methylene blue	2 Gm.

Dissolve in 100 cc. of a boiling-hot 5 per cent. aqueous solution of sodium borate.

Loeffler's Methylene Blue Solution:

Methylene Blue	0.5 Gm.
Alcohol	30.0 cc.
Tenth-normal Potassium Hydroxide V.S.	2.0 cc.
Distilled Water	98.0 cc.

Dissolve the methylene blue in alcohol, add the potassium hydroxide and distilled water. Filter.

Solution of Carbol Methyl Violet:

Alcoholic Solution of Methyl Violet 6B	10 cc.
Aqueous solution of Phenol (1 in 20), a sufficient quantity	
To make a solution measuring	100 cc.

Solution of Carbolfuchsin (Ziehl-Neelsen's Solution):

Fuchsin	1 Gm.
Dehydrated Alcohol	10 cc.

Dissolve and add 100 cc. of a 5 per cent. aqueous solution of phenol.

For Tubercle Bacilli.—*Solution of Carbolfuchsin (Ziehl-Neelsen's Solution).*

For Decolorizing.—*Ebner's Fluid:*

Hydrochloric Acid	2.5 cc.
Sodium Chloride	2.5 Gm.
Distilled Water	100.0 cc.
Alcohol	500.0 cc.

Prepare a solution.

Nitric Acid Decolorizing Solution: (Acid Alcohol)

Nitric Acid	30.0 cc.
Distilled Water, a sufficient quantity	
To make	100.0 cc.

Diluted Lugol's Solution: (Gram's Iodine Solution)

Iodine	1 Gm.
Potassium Iodide	2 Gm.
Distilled Water, a sufficient quantity	
To make	200 cc.

For Diphtheria Bacilli.—*Solution of Methylene Blue (Neisser's):*

Methylene Blue	0.5 Gm.
Alcohol	10.0 cc.
Diluted Acetic Acid (U. S. P.)	500.0 cc.

Ponder's Stain:

Toluidin Blue	0.02 Gm.
Glacial Acetic Acid	1.0 cc.
Dehydrated Alcohol	2.0 cc.
Distilled Water, a sufficient quantity	
To make	100.0 cc.

For Counter Staining.—*Loeffler's Methylene Blue Solution* (see page Gram's Stain) (*Aniline Water—Methyl Violet 6B Blue Solution*):

Aniline Oil	15 cc.
Saturated Alcoholic Solution of Methyl Violet 6B	7 cc.
Dehydrated Alcohol	10 cc.
Distilled Water, a sufficient quantity	
To make	100 cc.

Shake the aniline oil with 65 cc. of distilled water for several minutes; filter the resulting opalescent aniline water through a moistened filter, pour the filtrate into a solution prepared by mixing the other liquids and add sufficient distilled water to make 100 cc.

Diluted Carbolfuchsin Solution:

Solution of Carbolfuchsin	1 cc.
Distilled Water	4 cc.

Prepare a solution.

Bismarck Brown Solution:

Bismarck Brown	0.2 Gm.
Distilled Water	100.0 cc.

Prepare a solution.

CULTURE MEDIA.

Culture media require titration and subsequent adjustment to certain hydrogen ion concentration in order to insure constant and reliable results. For this purpose phenolphthalein has been generally adopted as the indicator.

Titration is made as follows.—In a white glazed porcelain dish put 5 cc. of the medium to be tested, add 45 cc. of recently boiled distilled water. Boil briskly for one minute. Add 1 cc. of phenolphthalein reagent (twice the strength of the official indicator solution). Titrate at once with a N/10 solution of sodium hydroxide. A faint but distinct pink colour indicates the true end point (neutrality).

The media listed herewith, are to be made neutral to phenolphthalein and adjustment is made to the reaction indicated in the text. (Plus 1 reaction requires the addition of 1 per cent. of N/1 acid to the medium at the neutral point).

Sterilization is preferably done in the autoclave (120° C.) for 15 minutes after the pressure reaches 15 pounds.

All glassware shall be sterilized in the dry oven at 170° C. for at least 1½ hours.

Bouillon Stock:

Lean Beef	500 Gm.
Or Extract of Beef	3 Gm.
Distilled water, a sufficient quantity	
To make	1000 cc.

Mix thoroughly 500 Gm. of finely minced lean beef with 1000 cc. of cold distilled water, heat it to boiling in a closely covered dish or flask and keep it at that temperature for one hour. If extract of beef is used to make bouillon stock, boil the solution for one-half hour. Filter the resulting bouillon through a well-wetted filter, until clear and use it as the basis for the following combinations:

Plain Bouillon:

Peptone	10 Gm.
Sodium Chloride	5 Gm.
Tenth-normal Sodium Hydroxide V.S.	
Bouillon stock each a sufficient quantity	
To make	1000 cc.

Dissolve the peptone and sodium chloride in the bouillon stock by means of heat and add sufficient deci-normal sodium hydroxide V.S. to bring the reaction to plus 1. Then filter the product through wetted filter, fill it into suitable containers and sterilize.

Glucose Bouillon:

Glucose (dry)	10 Gm.
Peptone	10 Gm.
Sodium Chloride	5 Gm.
Tenth-normal Dosium Hydroxide V.S.	
Bouillon Stock, each a sufficient quantity	
To make	1000 cc.

Dissolve the glucose, peptone, and sodium chloride in the bouillon stock by means of heat and add sufficient deci-normal sodium hydroxide V.S. to bring the reaction to the neutral point with phenolphthalein. Then filter the product through a well-wetted filter, fill it into suitable containers and sterilize by the discontinuous method.

Plain Gelatin:

Gelatin	100 Gm.
Peptone	10 Gm.
Sodium Chloride	5 Gm.
Tenth-normal Sodium Hydroxide V.S.	
Bouillon Stock, each a sufficient quantity	
To make	1000 cc.

Dissolve the gelatine, peptone, and sodium chloride in the bouillon stock by means of heat and add sufficient deci-normal sodium hydroxide V.S. to bring the reaction to plus 1. Filter the warmed product through filter paper, fill it into suitable containers and sterilize by the discontinuous method.

Glucose Gelatin:

Dextrose	10 Gm.
Gelatin	100 Gm.
Peptone	10 Gm.
Sodium Chloride	5 Gm.
Tenth-normal Sodium Hydroxide V.S.	
Bouillon stock, each a sufficient quantity	
To make	1000 cc.

Dissolve the glucose, gelatine, peptone, and sodium chloride in the bouillon stock by means of heat and add sufficient deci-normal sodium hydroxide V.S. to neutralize the resulting mixture to phenolphthalein. Then filter the product through paper, fill it into suitable containers and sterilize by the discontinuous method.

Plain Agar-Agar:

Agar, washed and dried for ½ hour at 105° C. before weighing	15 Gm.
Peptone	10 Gm.
Sodium Chloride	5 Gm.
Tenth-normal Sodium Hydroxide V.S.	
Bouillon stock, each a sufficient quantity	
To make	1000 cc.

Dissolve the agar, peptone, and sodium chloride in the bouillon stock by means of heat and add a sufficient quantity of deci-normal sodium hydroxide V.S. to bring the reaction of the mixture to plus 1. Then filter the warmed product through paper, fill it into suitable containers and sterilize.

Glucose Agar-Agar:

Dextrose	10 Gm.
Agar, washed and dried for one-half hour at 105 C. before weighing	15 Gm.
Peptone	10 Gm.
Sodium Chloride	5 Gm.
Tenth-normal Sodium Hydroxide V.S.	
Bouillon Stock, each a sufficient quantity	
To make	1000 cc.

Dissolve the glucose, peptone and sodium chloride in the bouillon stock by means of heat, and add sufficient quantity of the deci-normal sodium hydroxide V.S. to neutralize the resulting mixture to phenolphthalein. Then filter the warmed product through paper, fill it into suitable containers and sterilize by the discontinuous method.

Glycerin, Agar-Agar:

Glycerin	60 cc.
Agar, washed and dried for one-half hour at 105 C. before weighing	15 Gm.
Peptone	10 Gm.
Sodium Chloride	5 Gm.
Tenth-normal Sodium Hydroxide V.S.	
Bouillon Stock, each a sufficient quantity	
To make	1000 cc.

Dissolve the glycerin, agar, peptone, and sodium chloride in the bouillon stock by means of heat, and add a sufficient quantity of tenth-normal sodium hydroxide V.S. to neutralize the resulting mixture to phenolphthalein. Then filter the warmed product through paper to fill into suitable containers and sterilize.

Lactose-litmus Agar-Agar:

Sugar of milk	10 Gm.
Agar, washed and dried for one-half hour at 105 C. before weighing	15 Gm.
Peptone	10 Gm.
Sodium Chloride	15 Gm.
Tenth-normal Sodium Hydroxide V.S.	
Azolitmin Test Solution (see page 000)	
Bouillon Stock, each a sufficient quantity	
To make	1000 cc.

Dissolve the sugar of milk, agar, peptone, and sodium chloride in the bouillon stock by means of heat and add a sufficient quantity of deci-normal sodium hydroxide V.S. to neutralize the resulting mixture to phenolphthalein. Then filter the warmed product through paper, add a sufficient quantity of azolitmin solution to impart to the resulting mixture a pale blue colour, fill into suitable containers and sterilize by the discontinuous method.

Blood Serum Loeffler's Mixture.

Glucose Bouillon	150 cc.
Horse or Beef Blood Serum	750 cc.

Run the mixture of glucose bouillon and beef or horse blood serum into properly sterilized test tubles and coagulate it by means of heat so as to form a slanting surface for culture purposes.

Endo's Medium:

Beef Extract	5 Gm.
Peptone	10 Gm.
Agar, washed and dried for one-half hour at 105 C. before weighing	30 Gm.
Distilled Water to	1000 cc.

Dissolve with the aid of the water bath. Adjust to a neutral reaction to phenolphthalein. Filter the warmed product through cloth and cotton until clear. Sterilize.

When ready to make plates, prepare a 10 per cent. solution of anhydrous sodium sulphite. To 10 cc. of the sodium sulphite solution add 2 cc. of the fuchsin stock solution (basic fuchsin 10 Gm., alcohol 100 cc.), and steam five minutes in the Arnold or on a water bath. To each 100 cc. of the agar mixture, add 1 gram of lactose, dissolve on a water bath and add one-half cc. of the fuchsin sulphite solution.

TABLES OF THE U. S. P. X.

Atomic and Molecular Weights.

(U.S.)

This list contains the official chemicals and reagents of a definite conposition, and also some that are not official but which are likely to be required in stoichiometrical calculations. The figures in the list given below are based upon the Table of International Atomic Weights (1921), with Oxygen taken as 16. The elementary substances are also given in a separate list. In the case of a few salts, for which this Pharmacopœia has given no formula on account of the difficulty of securing an obsolutely uniform composition, the theoretical formula has been inserted merely for information. In the case of many hydrated compounds the formula and molecular weight of the corresponding anhydrous salt have also been given to save time in making calculations.

		O=16
Acetaldehyde (Acetic Aldehyde)	CH_3CHO	44.04
Acetanilid (Phenylacetamide)	$C_6H_5NH.CH_3CO$	135.12

---

* Barometer 760 mm. Air one-half saturated with moisture.

‖ If temperature of observation is above 15.56° C. (60.4° F.), look for percentage correction in the following table.

† Correction subtractive if barometer is above, additive if below, 760 mm. If barometer readings are in inches reduce to millimeters by multiplying by 25.4.

‡ Corresponding with a difference in specific gravity of 0.0001.

§ The figures on this line across the page are for fractional percentages below 1.

NOTE.—The figures of these Alcoholometric Tables are based on tables issued by the U. S. Bureau of Standards.

Alcoholometric Table—*Continued.*

Acid and Alkali Tables.

U.S.

Specific gravity.—The term "specific gravity" in the tables which follow represents the quotient obtained by dividing the weight of a volume of the liquid by the weight of an equal volume of distilled water, both measured at the same temperature and weighed in air with brass weights. The tables include specific gravity figures for 25° C., the official temperature and also for 15° C.

Percentage.—The percentage strength of acetic, hydrochloric, nitric, and sulphuric acids and of ammonia water can be calculated from their specific gravity by reference to the tables. For the determination of the percentage by the specific gravity, it is preferable to take the specific gravity at the temperature for which figures are given in the tables, at 25° or 15° C. If it is found inconvenient to determine it at these temperatures, the specific gravity may be taken at the prevailing room temperature and the correction for the specific gravity at standard temperature made from the figures in column 4 and the per cent. of acid or ammonia water ascertained from columns 2 (or 3) and 5 in the following manner:

Example: A sample of dilute sulphuric acid has an apparent specific gravity at 21° C. (room temperature), by a pycnometer standardized at 25° C., of 1.1457. The correction for 4° C. (subtractive) is $0.000561 \times 4 = 0.0022$ (from column 4). The corrected specific gravity, $1.1457 - 0.0022 = 1.1435$. The nearest lower figure in column 2 is 1.1400, showing (column 1) 20 per cent. of acid. For the fractional per cent., multiply the difference ($1.1435 - 1.1400 = 0.0035$, taken as 35) by 0.0132 (column 5); the product is 0.462. The strength is therefore 20.462 per cent.

Normality.—Column 6 shows the "normality,"—*i.e.*, the neutralizing power of the acid or alkali. If the figure in this column is 2.74, one volume of the acid diluted with water to make 2.74 volumes will be of "normal" strength. It is therefore easy by the aid of these figures to prepare volumetric solutions of approximately any desired strength $\left(\frac{N}{1}, \frac{N}{10}, \frac{N}{40}, \text{etc}\right)$, from an acid or alkali or known percentage strength. For accurate work such solutions must of course be standardized by the usual methods. (See Volumetric Solutions).

The chief use, however, of the normality column is for the determination directly by titration of the percentage strength of an acid or alkali of unknown specific gravity.

Example: 1 cc. (accurately measured) of a sample of acetic acid of unknown strength is found to require for neutralization 4.62 cc. of normal potassium hydroxide V.S. The nearest lower figure in column 6 is 4.465, corresponding with 26 per cent. For the fractional per cent., multiply the difference ($4.620 - 4.465 = 0.155$, taken as 15.5) by 0.0565 (column 7). The product is 0.8757. The strength is therefore 26.87+ per cent.

Acetic Acid

---

* Below this point the specific gravity diminishes as the strength of the acid increases.

NOTE: If the specific gravity of the acid is greater than 1.045, mix some of the acid with an equal weight of water and take the specific gravity of the mixture, then multiply the corresponding percentage taken from the table by two. It is better, however, to determine the strength of any sample of acetic acid by its normality.

To find the volume per cent. of official Acetic Acid (36 per cent.) multiply the "normality" by 16.01. For the volume per cent. of Acetic Acid ($HC_2H_3O_2$), multiply the "normality" by 5.751. For the volume per cent. of official Diluted Acetic Acid (6 per cent.), multiply the "normality" by 99.5.

100	1.8317	1.8391	0.001074	......	37.221	......

Note that the specific gravity diminishes in acids of more than 97.5 per cent. strength as the percentage increases.

NOTE: To find the per cent. of SO_3, multiply the per cent. of H_2SO_4 by 0.81629. To find the per cent. of SO_4 multiply the per cent. of H_2SO_4 by 0.97941. To find the volume per cent. of official Sulphuric Acid (94 per cent.), multiply the "normality" by 2.857. For the volume per cent. of official Diluted Sulphuric Acid (10 per cent.), multiply the "normality" by 46.10.

To find the weight in grammes of H_2SO in 100 mils, multiply the specific gravity by the per cent. of H_2SO_4.

Table of Percentage and Specific Gravity of Ammonia. U. S. P. X.

Per Cent. NH_3	Sp. gr. app. $\frac{25^\circ \text{ C.}}{25^\circ \text{ C.}}$	Sp. gr. app. $\frac{15^\circ \text{ C.}}{15^\circ \text{ C.}}$	Correction of specific gravity for 1° C.*	Fractional per cent.†	Normality. 1 mil requires normal HCl mils.	Per cent. = 0.01 mil normal HCl.

* Add if the temperature is above, subtract if it is below, the standard.

† Corresponding with a difference in specific gravity of 0.0001.

‡ The figures in this line across the page are for fractional percentages below **1.**

NOTE: To find the per cent. of NH_4 multiply the per cent. of NH_3 by 1.0592. To find the volume per cent. of official Ammonia Water (10 per cent.) multiply the "normality" by 17.83. For the volume per cent. of official Stronger Ammonia Water (28 per cent.), multiply the "normality" by 6.803.

RELATIONS BETWEEN THERMOMETERS.

In *Fahrenheit's* thermometer, the freezing point of water is placed at 32°, and the boiling point at 212°, and the number of intervening degrees is 180.

The *centigrade* or *Celsius's* thermometer, which is now recognized in the U. S. Pharmacopœia and has been adopted generally by scientists, marks the freezing point *zero*, and the boiling point 100°.

In *Réaumur's* thermometer the freezing point is at *zero*, and the boiling point at 80°.

In *De Lisle's* thermometer, used in Russia, the graduations begins at the boiling point, which is marked *zero*, while the freezing point is placed at 150°.

From the above statement, it is evident that 180 degrees of Fahrenheit are equal to 100° of the Centigrade, 80° of Réaumur, and 150° of De Lisle; or 1 degree of the first is equal to $\frac{5}{9}$ of a degree of the second, $\frac{4}{9}$ of a degree of the third, and $\frac{5}{6}$ of a degree of the last. It is easy, therefore, to convert the degrees of one into the equivalent number of degrees of the other; but in ascertaining the corresponding points upon the different scales, it is necessary to take into consideration their different modes of graduation. Thus, as the zero Fahrenheit is 32° below the point at which that of the Centigrade and of Réaumur is placed, this number must be taken into account in the calculation.

1. If any degree on the *Centigrade* scale, either above or below zero, be multiplied by 1.8 the result will, in either case, be the number of degrees above or below 32° or the freezing point of *Fahrenheit*.
2. The number of degrees between any point of *Fahrenheit's* scale and 32°, if divided by 1.8, will give the corresponding point on the *Centigrade*.

Thermometric Equivalents.

Formula for deriving above correction: Subtract algebraically the apparent specific gravity from 1.000 and multiply the remainder by 0.0011773. It is additive for specific gravities below, subtractive for those above, 1.000.

NOTE: The correction for reducing true to apparent specific gravity is found by subtracting algebraically 1.000 from the true specific gravity and multiplying the remainder by the factor 0.0011765. It is subtractive for specific gravities below, additive for those above, 1.000.

Calibration of Pycnometers.

						1	=	60

The Imperial Standard Troy weight, at present recognized by the British laws, corresponds with the Apothecaries' weight in pounds, ounces, and grains; but differs from it in the division of the ounce, which according to the former scale, contains twenty pennyweights, each weighing twenty-four grains.

In converting the weights of liquids heavier or lighter than water into measures, or conversely, a correction must be made for specific gravity. In converting weights into measures‘ the calculator may proceed as if the liquid were water, and the obtained measure will be to the true measure *inversely* as the specific gravity. In the converse operation, of turning measures into weights, the same assumption may be made, and the obtained weight will be to the true weight *directly* as the specific gravity.

Drops

Small quantities of liquid medicines are often administered by *drops*, each of which is often considered equivalent to a minim, or the sixtieth part of a fluidrachm. The drop of water and of aqueous fluids is, sometimes, about that size; but the same is by no means the case with all medicinal liquids, and the drop even of the same liquid varies much in bulk, according to the circumstances under which it is formed. This is, therefore, an uncertain mode of estimating the quantity of liquids, and should be superseded where minim measures can be had. Certain rules, however, influence the formation of drops, which will enable us to form some notion of their probable relative number, in the same amount of liquid when possessed of the requisite data. Thus, the heavier the liquid, the smaller, other things being equal, is the size of the drops, and the greater their number in a given measure. The drop of chloroform, for example, which is a very heavy liquid, is very small, much smaller than that of alcohol or ether. The greater or less viscidity and greater or less mobility of the liquid have much influence, the former in increasing, the latter in diminishing the size of the drops. The adhesiveness of liquids, which opposes their disposition to leave the surface from which they fall, requires a greater mass to overcome it, and consequently augments the size of the drop. The rapidity of the movement acts in a contrary direction, and the drop from a full bottle should be less than from one more or less emptied. The broader the surface from which they fall, the greater is their size. The drops from a thick-lipped bottle are larger than from one with thin lips.

The results stated in the table below were obtained by Stephen L. Talbot. They may be relied on as accurate, and in most cases correspond with the results obtained by Durand and Procter (see *A. J. P.*, i, 169; 1865, p. 389; 1880, p. 337), but should be considered as indicating only the relative number of drops afforded by the several liquids mentioned under the specific conditions of the experiment with the preparations then official. While modifications in some of the methods of making the preparations and while under other circumstances than those of Talbot's experiments, entirely different results might be obtained as relates to each liquid the matter is of so much interest that, in the absence of any later data of the kind, it has been felt to be worthy of preservation as at least an approximate indication of the size of a "drop".

TABLES SHOWING SPECIFIC GRAVITY CORRESPONDING WITH DEGREES OF HYDROMETERS.

Baumé's hydrometer is still largely employed. In this instrument the specific gravity of distilled water is assumed as the zero of the descending scale in relation to fluids heavier than itself, and as ten on the ascending scale in relation to lighter fluids. In the following tables the specific gravity of liquids is given corresponding with the several degrees of this hydrometer. The first column of specific gravities is taken from the French Codex. The second column is based on the calculations of Huss. The third column was calculated by Henry Pemberton of Philadelphia, in 1851. The figures in this column correspond with the degrees of the hydrometers formerly prepared by W. H. Pile.

The following formulas, furnished by Pile, may prove useful by enabling any one to calculate the sp. gr. corresponding with the several degrees of Baumé's hydrometer, and, conversely, the degree of Baumé corresponding with the sp. gr.

1. *For Liquids lighter than Water.*—The following formulas give the sp. gr. as represented in the first column in the foregoing table; or, the specific gravity being known, give the corresponding degree of Baumé.

$$\frac{144}{\text{B}^\circ + 134} = \text{sp. gr.; and } \frac{144}{\text{sp. gr.}} - 134 = \text{B}^\circ.$$

The following formulas apply to the third column of specific gravities.

$$\frac{140}{\text{B}^\circ + 130} = \text{sp. gr.; and } \frac{140}{\text{sp. gr.}} - 130 = \text{B}^\circ.$$

2. *For Liquids heavier than Water.*—For the first column, $\frac{144}{144 - \text{B}^\circ} = \text{sp. gr.}$, and $144 - \frac{144}{\text{sp. gr.}} = \text{B}^\circ$; for the third, $\frac{145}{145 - \text{B}^\circ} = \text{sp. gr.}$, and $145 - \frac{145}{\text{sp. gr.}} = \text{B}^\circ$.

Gay-Lussac's centesimal alcoholmeter is applicable only to alcohol. The scale of this instrument is divided into 100 unequal degrees, the zero corresponding to pure water, and 100° to absolute alcohol ; and every intermediate degree expresses the percentage of pure alcohol, by measure, contained in the liquors examined. Thus, when the instrument stands at 40° in any alcoholic liquid, it indicates that 100 measures of the liquid contain 40 of pure alcohol and 60 of water. But, as it was graduated for the temperature of 59° of Fahrenheit, the liquors to be tested should be brought to that temperature. *Tralles's centesimal alcoholmeter* is the one used by the U. S. Government in gauging the strength of spirit, and is generally employed in this country by distillers and wholesale dealers in the purchase and sale of alcoholic liquors. The scale of this instrument is, like Gay-Lussac's, divided into 100 unequal parts, each corresponding to the percentage by volume of pure alcohol contained in the liquors examined. As the sp. gr. of water is considered as unity at its temperature of greatest density, 39.8° F., and the degrees of this scale are calculated for 60° F., the zero, corresponding to the density of water, will represent a sp. gr. of .9991.

The table of Tralles on page 1752 gives the percentage of alcohol *by volume* corresponding with the specific gravity. Under the heading of Alcohol tables (see page 1757), a table of the percentage by weight corresponding with the sp. gr. is given. By means of these tables, in connection with the alcoholmeter, every problem that can arise in reference to the strength of spirituous liquors can be solved ; and by the appended table, giving the value of Baumé's degrees in those of Tralles, the facility is still further extended.

Sikes's hydrometer is used in Great Britain in the collection of the excise revenue : it is a brass instrument having a spherical bulb, with a weight at the bottom to make it float upright ; the stem is divided into twenty parts, and every other division numbered, from 0 to 10. A series of nine weights are furnished with the instrument, numbered from 10 to 90 ; these are to be added to the weight at the bottom to cause the hydrometer to sink, so that a reading may be had on the graduated scale ; this reading added to the number on the weight employed, gives a figure which indicates the strength of the spirit by referring to a table which accompanies the instrument.

Jones's hydrometer is similar to Sikes's, but by many is regarded as an improvement on it.

PART III

SECTION II

NATIONAL FORMULARY

The National Formulary, published by the American Pharmaceutical Association, was originally planned as a convenience for druggists by providing them with standardized formulas for preparations called for either by the laity or by physicians. Under the Federal law of 1906 it became a legal standard for medicines in the United States. This change in its status has led to some modification in the character of the N. F.; it has been divided in two parts: first a collection of formulas of the same type as originally composed the book, and second a description of such crude drugs employed in these formulas as are not recognized by the Pharmacopœia, with tests for their quality. This second part of the N. F., being essentially of the same category as the Pharmacopœial descriptions, has been included in Part I of the present work. The galenicals of the N. F., being of less importance, are given only in abstract in this place.

ACETUM AROMATICUM. N. F.

Aromatic Vinegar [Acet. Arom.]

It contains the volatile oils of lavender, rosemary, juniper, peppermint, cinnamon, lemon and clove, dissolved in alcohol, acetic acid and water, and is used as a stimulating inhalant.

ACIDUM NITROHYDROCHLORICUM. N. F.

Nitrohydrochloric Acid [Acid. Nitrohydrochl.]

Nitromuriatic Acid; Aqua Regia.

This differs materially from the acid of the same name which is official in the Br. It is made by mixing eighteen parts of nitric and eighty-two parts of hydrochloric acids. It is a golden yellow, fuming liquid with a chlorinous odor; it becomes lighter in color when kept, but only the golden fluid should be dispensed. The N. F. directs that unless it immediately liberates iodine from aqueous solution of potassium iodide it should not be dispensed. For description of chemical and therapeutic properties see *Acidum Nitrohydrochloricum*, Part I.

Dose, three to five minims (0.2–0.3 cc.).

ACIDUM NITROHYDROCHLORICUM DILUTUM. N. F.

Diluted Nitrohydrochloric Acid [Acid. Nitrohydrochl. Dil.]

Diluted Nitromuriatic Acid.

This represents approximately 22 per cent. of the nitrohydrochloric acid, N. F.

Dose, fifteen to thirty minims (1–2 cc.).

AMPULLÆ.

Ampules

These are small, hermetically sealed containers which are filled with a sterile solution of a medicinal agent intended for hypodermic injection. In our opinion the name is an unfortunate one as it applies to the container rather than the contents; the British name, for the corresponding preparation, of *Injectiones Hypodermicæ* seems more appropriate.

The amount of solution in each is a little more than 1 cc. (except one which is 2 cc.); this is to allow for the small amount of liquid which inevitably remains in the container when the physician fills his syringe from it.

AMPULLÆ CAFFEINÆ SODIO BENZOATIS. N. F.

Ampules of Caffeine Sodio-Benzoate [Ampul. Caf. Sod.-Benz.]

Each ampule represents 0.5 Gm. (eight grains) of the U. S. P. caffeine sodio-benzoate in sterile distilled water.

Dose, one ampule.

AMPULLÆ CAMPHORÆ.

Ampules of Camphor

Each ampule contains 0.2 Gm. (three grains) of camphor dissolved in cottonseed oil. It is used as a circulatory stimulant.

Dose, one ampule.

AMPULLÆ EMETINÆ HYDROCHLORIDI. N. F.

Ampules of Emetine Hydrochloride [Ampul. Emet. Hydrochl.]

Each ampule contains 0.03 Gm. (one-half grain) of emetine hydrochloride. It is used in the treatment of dysentery.

Dose, one ampule.

AMPULLÆ IODI. N. F.

Ampules of Iodine

Iodine Swabs.

This is a solution of 3.5 per cent. of iodine and 2.5 per cent. of potassium iodide, in 70 per cent. alcohol. It is intended as a surgical antiseptic, being of a more desirable strength for this purpose than the U. S. tincture of iodine.

AMPULLÆ QUININÆ ET UREÆ HYDROCHLORIDI. N. F.

Ampules of Quinine and Urea Hydrochloride [Ampul. Quin. Et Urea Hydrochl.]

Each contains 0.5 Gm. of quinine and urea hydrochloride. It affords a convenient method of obtaining the therapeutic action of quinine by hypodermic injection and is especially employed in pneumonia.
Dose, one ampule.

AMPULLÆ QUININÆ DIHYDROCHLORIDI. N. F.

Ampules of Quinine Dihydrochloride [Ampul. Quin. Dihydrochl.]

Each ampule contains 0.5 Gm. of the acid hydrochloride of quinine, the acidity of the solvent being regulated by titration. It is intended for the hypodermic administration of quinine, especially in severe cases of malarial fever.
Dose, one ampule.

AMPULLÆ SODII CACODYLATIS. N. F.

Ampules of Sodium Cacodylate [Ampul. Sod. Cacodyl.]

Each ampule contains 0.3 Gm. (five grains) of sodium cacodylate.
Dose, one ampule.

AQUA HAMAMELIDIS. N. F.

Hamamelis Water [Aq. Hamam.]

Witch Hazel Water; Distilled Extract of Witch Hazel.

This is a popular, but useless, embrocation made by distillation of hamamelis twigs. It contains a trace of volatile oil but no therapeutically active substance; even the alcohol present is in too small a proportion to exert any beneficial action.

AQUA PHENOLATA. N. F.

Phenolated Water [Aq. Phenol.]

Carbolic Acid Water; Phenolis Soluto, *P. I.*

This is a 2 per cent. solution of phenol in distilled water and is used as a lotion, gargle, etc.

CAFFEINÆ SODIO-SALICYLAS. N. F.

Caffeine Sodio-Salicylate [Caff. Sod.-Sal.]

This powder contains equal parts of caffeine and sodium salicylate. It is used for the same purposes as the caffeine sodio-benzoate (see Part I). The *dose* is three grains (0.2 Gm.).

CATAPLASMA KAOLINI. N. F.

Cataplasm of Kaolin [Catapl. Kaolin.]

This is a mixture of kaolin, glycerin, boric acid, thymol and oils of peppermint and wintergreen. It is used as a substitute for poultices. It should be applied as hot as can be comfortably endured.

CERATUM CAMPHORÆ. N. F.

Camphor Cerate [Cerat. Camph.]

Camphorated Ointment.

This preparation is composed of 10 per cent. of camphor liniment in a cerate base.

CERATUM PLUMBI SUBACETATIS. N. F.

Cerate of Lead Subacetate [Cerat. Plumb. Subacet.]

Goulard's Cerate.

This well-known cerate contains 20 per cent. of Goulard's extract mixed with a cerate base containing a little camphor. It is used as an astringent and sedative dressing.

CERATUM RESINÆ COMPOSITUM. N. F.

Compound Rosin Cerate [Cerat. Resin. Co.]

Deshler's Salve.

This popular cerate contains rosin, yellow wax, suet, turpentine, and linseed oil. It is used as a stimulating dressing.

CHARTA POTASSII NITRATIS. N. F.

Potassium Nitrate Paper [Chart. Pot. Nit.]

This is made by saturating unsized paper in a strong solution of potassium nitrate and drying. It is used in asthma by burning it and inhaling the smoke.

CHLORAL CAMPHORATUM. N. F.

Camphorated Chloral [Chloral Camph.]

A eutectic mixture of equal parts of hydrated chloral and camphor, used as a local anodyne and counter-irritant.

COLLODIUM BITUMINIS SULPHONATI. N. F.

Collodion of Sulphonated Bitumen [Collod. Bitum. Sulphon.]

Ichthyol Collodion.

This contains 10 per cent. of sulphonated bitumen in flexible collodion. It does not seem to us a very efficacious way of applying ichthyol.

COLLODIUM SALICYLICUM COMPOSITUM. N. F.

Compound Salicylic Collodion [Collod. Sal. Co.]

Corn Collodion; Collodium Salicylatum Compositum.

It contains salicylic acid, extract of cannabis, and flexible collodion. Used for the removal of corns.

COLLODIUM STYPTICUM. N. F.

Styptic Collodion [Collod. Stypt.]

This is a 20 per cent., by weight, solution of tannic acid in flexible collodion. It is used as a styptic application to cuts and small wounds.

CONFECTIO ROSÆ. N. F.

Confection of Rose [Confect. Ros.]

It is used principally as a pill excipient or vehicle. (See *Confectio Rosæ Gallicæ*, Part I.)

CONFECTIO SENNÆ. N. F.

Confection of Senna [Confect. Senn.]

This is very similar to the Br. confection of senna (see Part I).
Dose, sixty grains, 4 Gm., representing six grains of senna and nine and a half grains of cassia fistula.

CURATIO PARAFFINI. N. F.

Paraffin Dressing [Curat. Paraf.]

Paraffin Film.

Under this peculiar title is a paraffin softened by the addition of white petrolatum and olive oil, and containing 1 per cent. of resorcinol and 2 per cent. of eucalyptol. It is intended as a local application for burns.

DENTIFRICIUM. N. F.

Dentifrice [Dentif.]

Tooth-powder; Oxidizing Tooth-powder.

This tooth-powder contains soap, sugar and flavoring, prepared chalk, precipitated calcium carbonate and 5 per cent. of sodium perborate; because of the abrasive properties of precipitated calcium carbonate it would have been better, in our opinion, to have substituted for it an increase in the amount of chalk.

DENTILINIMENTUM ACONITI COMPOSITUM. N. F.

Compound Dental Liniment of Aconite [Dentilin. Aconit. Co.]

This contains 36 per cent. of menthol and 13.5 per cent. of chloroform in tincture of aconite. It is a powerful counter-irritant and local anesthetic, used in neuralgic conditions of the gums and in toothache. It should not be confounded with the compound liniment of aconite which is used externally.

DENTILINIMENTUM ACONITI ET IODI COMPOSITUM. N. F.

Compound Dental Liniment of Aconite and Iodine [Dentilin. Aconit. et Iod. Co.]

Refrigerant Counter-irritant.

This contains 2.2 per cent. of each of menthol and iodine and 16.5 per cent. of chloroform dissolved in tincture of aconite. It is used for similar properties to the above but is less actively counter-irritant but more antiseptic.

ELIXIR ALETRIDIS COMPOSITUM. N. F.

Compound Elixir of Aletris [Elix. Aletrid. Co.]

This contains, in each fluidrachm, 3¾ minims of the fluidextracts of aletris, mitchella, helonias and caulophyllum with 1⅞ minims of viburnum opulus. As none of these drugs are of much value and as the quantities present are ridiculously minute it is evident that the elixir is of no great use. It is intended for dysmenorrhea.

Dose, one to four fluidrachms (4–15 cc.).

ELIXIR AMMONII BROMIDI. N. F.

Elixir of Ammonium Bromide [Elix. Ammon. Brom.]

It is made with ammonium bromide and a diluted and sweetened aromatic elixir. It contains 5 grains of ammonium bromide in 1 fluidrachm of finished elixir.

The *dose* is one to four fluidrachms (4–15 cc.).

ELIXIR AMMONII VALERATIS. N. F.

Elixir of Ammonium Valerate [Elix. Ammon. Valer.]

Elixir Ammonii Valerianatis, *N. F. III.*

This preparation is made with ammonium valerate and chloroform dissolved in aromatic elixir, colored with cudbear and flavored with vanilla. It contains 2 grains of ammonium valerate in 1 fluidrachm of finished elixir.

The *dose* is one fluidrachm (4 cc.).

ELIXIR AMYGDALÆ COMPOSITUM. N. F.

Compound Elixir of Almond [Elix. Amygdal. Co.]

This is a flavoring elixir of very low alcoholic strength (5 per cent.) containing oil of bitter almond, vanillin, and orange flower water as the essential ingredients.

ELIXIR ANISI. N. F.

Elixir of Anise [Elix. Anis.]

This is a misnamed elixir containing a very low proportion of alcohol. It contains anethol, oil of fennel, spirit of bitter almond, alcohol, syrup and water. Used as a vehicle.

ELIXIR AROMATICUM RUBRUM. N. F.

Red Aromatic Elixir [Elix. Arom. Rub. Red Elixir]

This is the U. S. P. aromatic elixir colored red with cudbear.

ELIXIR AURANTII AMARI. N. F.

Elixir of Bitter Orange [Elix. Aurant. Amar.]

Elixir Curassoa; Elixir of Curaçao.

This is an improvement upon the former elixir of Curaçao. It contains oil of bitter orange, tincture of bitter orange peel, and orange flower water as the flavoring constituents.

ELIXIR BISMUTHI. N. F.

Elixir of Bismuth [Elix. Bismuth.]

This elixir is made from glycerite of bismuth, glycerin, distilled water, and aromatic elixir, and each teaspoonful represents the equivalent of 3 grains (0.19 Gm.) of bismuth sodium tartrate. This is used as an intestinal astringent, but does not possess the therapeutic virtues of the insoluble bismuth salts.

The *dose* is one fluidrachm (4 cc.).

ELIXIR BROMIDORUM QUINQUE. N. F.

Elixir of Five Bromides [Elix. Bromid. Quinq.]

What the advantage is of having five different salts of hydrobromic acid in combination, is not very obvious; they are sodium, potassium, calcium, lithium and ammonium bromides. The total quantity of bromide present is 15 grains in each fluidrachm.

Dose, one fluidrachm (4 cc.).

ELIXIR BROMIDORUM TRIUM. N. F.

Elixir of Three Bromides [Elix. Tri. Brom.]

This elixir contains in each fluidrachm 4½ grains each of ammonium, potassium and sodium bromides.

The *dose* is one fluidrachm (4 cc.).

ELIXIR BUCHU. N. F.

Elixir of Buchu [Elix. Buchu]

It contains fluidextract of buchu, alcohol, and aromatic elixir. About 7½ grains of buchu are represented by 1 fluidrachm of finished elixir.

The *dose* is one to four fluidrachms (4–15 cc.).

ELIXIR BUCHU COMPOSITUM. N. F.

Compound Elixir of Buchu [Elix. Buchu Co.]

Compound fluidextract of buchu is used instead of the simple fluidextract. About 15 minims of compound fluidextract of buchu are represented in 1 fluidrachm of finished elixir.

The *dose* is one to four fluidrachms (4–15 cc.).

ELIXIR BUCHU ET POTASSII ACETATIS. N. F.

Elixir of Buchu and Potassium Acetate [Elix. Buchu et Pot. Acet.]

This elixir contains 5 grains of potassium acetate and the equivalent of 7½ grains of buchu in 1 fluidrachm of finished elixir. It is used in cystitis with acid urine.

The *dose* is one to four fluidrachms (4–15 cc.).

ELIXIR BUCHU, JUNIPERI ET POTASSII ACETATIS. N. F.

Elixir of Buchu, Juniper and Potassium Acetate [Elix. Buchu, Junip. et Pot. Acet.]

Each fluidrachm of this represents 8½ minims of fluidextract of buchu, half that quantity of juniper and about 3 grains of potassium acetate. The proportion of active ingredients is so small that one is forced to the conclusion that the most potent substance, in this elixir, is the alcohol.

Dose, one to four fluidrachms (4–15 cc.).

ELIXIR CALCII ET SODII GLYCEROPHOSPHATUM. N. F.

Elixir of Calcium and Sodium Glycerophosphates [Elix. Calc. et Sod. Glycerophos. Elixir Glycerophosphatum, N. F. III]

This elixir contains 1 grain of sodium glycerophosphate and ½ grain calcium glycerophosphate in each fluidrachm.

The *dose* is one to four fluidrachms (4–15 cc.).

ELIXIR CALCII LACTOPHOSPHATIS. N. F.

Elixir of Calcium Lactophosphate [Elix. Calc. Lactophos.]

This elixir contains about ½ grain of calcium phosphate in 2 fluidrachms of finished elixir.

The *dose* is two to six fluidrachms (8–22 cc.).

ELIXIR CARDAMOMI COMPOSITUM. N. F.

Compound Elixir of Cardamom [Elix. Card. Co.]

This is a new elixir of low alcoholic strength (9 per cent.) and pleasantly flavored with cardamom. It is used as a vehicle and flavoring agent.

ELIXIR CARNIS ET FERRI. N. F.

Elixir of Beef and Iron [Elix. Carn. et Ferr.]

Replacing Vinum Carnis et Ferri, *N. F. IV.*

There is little material difference between this and the formerly official wine, except in flavor. It contains about 2 grains of beef extract and half a grain of iron and ammonium citrate in each fluidrachm, the menstruum being 20 per cent. of alcohol. The old preparation was enormously abused; let us hope the change in flavor will lessen its popularity as a tipple.

Dose, two to six fluidrachms (8–23 cc.).

ELIXIR CASCARÆ SAGRADÆ. N. F. Elixir Rhamni Purshianæ, N. F. III

Elixir of Cascara Sagrada [Elix. Cascar. Sagr.]

An advantageous change in the formula of this is the substitution of aqueous elixir of glycyrrhiza in the place of aromatic elixir. It is a mixture of equal parts of aromatic fluidextract of cascara and elixir of glycyrrhiza.

The *dose* is one-half to one fluidrachm (2–4 cc.).

ELIXIR CASCARÆ SAGRADÆ COMPOSITUM. N. F. Elixir Rhamni Purshianæ Compositum, N. F. III

Compound Elixir of Cascara Sagrada [Elix. Cascar. Sagr. Co. Laxative Elixir]

It contains about 7½ minims of aromatic fluidextract of cascara to each fluidrachm in addition to small amounts of senna and juglans. It is used as a laxative.

The *dose* is one to three fluidrachms (4–11 cc.).

ELIXIR CATARIÆ ET FOENICULI. N. F.

Elixir of Catnep and Fennel [Elix. Catar. et Foenic.]

This contains 10 per cent. of the fluidextract of catnep with 1.75 per cent. of sodium bicarbonate and traces of oils of fennel and spearmint. It is intended as a carminative for infants.

Dose, for an infant ten to thirty minims (0.6–2 cc.).

ELIXIR CATHARTICUM COMPOSITUM. N. F.

Compound Cathartic Elixir [Elix. Cathart. Co.]

This elixir represents, in each fluidrachm, about 7½ grains of frangula together with 5½ of senna and 3 of rhubarb, and is flavored with peppermint and aromatic elixir.

The *dose* is from one to three fluidrachms (4–12 cc.).

ELIXIR CHLORIDORUM. N. F.

Elixir of Chlorides [Elix. Chlorid.]

Elixir of Four Chlorides.

This complex elixir contains in each fluidrachm about 1-64th grain of bichloride of mercury, 1-100th grain of arsenic trioxide and ¾ grain of ferric chloride and 5 minims of diluted hydrochloric acid. Such heterogeneous mixtures are much better reserved for extemporaneous prescription.

Dose, one to two fluidrachms (4–8 cc.).

ELIXIR CINCHONÆ ALKALOIDORUM. N. F. Elixir Cinchonæ, N. F. III

Elixir of Cinchona Alkaloids [Elix. Cinchon. Alk.]

Elixir Calisaya, Alkaloidal.

This elixir is now made from the alkaloids instead of the bark direct, and is simply a solution of cinchona alkaloids in aromatic elixir colored with cudbear. It contains about 1 grain of quinine sulphate and ½ grain each of cinchonidine and cinchonine sulphates in 1 fluidounce of finished elixir. It is used as a bitter, especially in conjunction with more active drugs.

The *dose* is two to four fluidrachms (8–15 cc.).

ELIXIR CINCHONÆ ALKALOIDORUM ET FERRI. N. F. Elixir Cinchonæ et Ferri, N. F. III

Elixir of Cinchona Alkaloids and Iron [Elix. Cinchon. et Ferr.]

Ferrated Elixir of Calisaya, Alkaloidal.

This elixir contains 4 grains of soluble ferric phosphate in 2 fluidrachms of finished elixir. It is used as a chalybeate tonic.

The *dose* is two to four fluidrachms (8–15 cc.).

ELIXIR CINCHONÆ ALKALOIDORUM, FERRI, BISMUTHI ET STRYCHNINÆ. N. F. Elixir Cinchonæ, Ferri, Bismuthi et Strychninæ, N. F. III

Elixir of Cinchona Alkaloids, Iron, Bismuth and Strychnine [Elix. Cinchon., Ferr., Bism. et Strych.]

Elixir of Calisaya, Alkaloidal, with Iron, Bismuth and Strychnine.

This irrational elixir contains 1–100th of a grain of strychnine sulphate, in each fluidrachm dissolved in elixir of cinchona alkaloids, iron and bismuth.

The *dose* is one fluidrachm (4 cc.).

ELIXIR CINCHONÆ ALKALOIDORUM, FERRI ET BISMUTHI. N. F.

Elixir of Cinchona Alkaloids, Iron and Bismuth [Elix. Cinchon., Ferr. et Bism.]

Elixir of Calisaya, Alkaloidal, with Iron and Bismuth.

This polypharmaceutical preparation contains 3¾ minims of glycerite of bismuth, about 3½ grains of soluble ferric phosphate, in 2 fluidrachms of finished elixir.

The *dose* is two fluidrachms (8 cc.).

ELIXIR CINCHONÆ ALKALOIDORUM, FERRI ET STRYCHNINÆ. N. F. Elixir Cinchonæ, Ferri et Strychninæ, N. F. III

Elixir of Cinchona Alkaloids, Iron and Strychnine [Elix. Cinchon., Ferr. et Strych.]

Elixir of Calisaya, Alkaloidal, with Iron and Strychnine.

This elixir contains 1–100th of a grain of strychnine sulphate and 2 grains of soluble ferric phosphate in 1 fluidrachm of finished elixir, and is used as a bitter tonic.

The *dose* is one to three fluidrachms (4–11 cc.).

ELIXIR CORYDALIS COMPOSITUM. N. F.

Compound Elixir of Corydalis [Elix. Coryd. Co.]

This elixir contains about 3 grains of potassium iodide in 1 fluidrachm of finished elixir, with small quantities of the fluidextracts of corydalis, stillingia, xanthoxylum and blue flag.

The *dose* is one fluidrachm (4 cc.).

ELIXIR ERIODICTYI AROMATICUM. N. F.

Aromatic Elixir of Eriodictyon [Elix. Eriodict. Arom.]

Aromatic Elixir of Yerba Santa; Elixir Corrigens.

This elixir is made from fluidextract of eriodictyon, syrup and compound elixir of taraxacum. It is used chiefly as a vehicle for disguising the taste of quinine sulphate and other bitter substances.

The *dose* is one fluidrachm (4 cc.).

ELIXIR EUPHORBIÆ COMPOSITUM. N. F.

Compound Elixir of Euphorbia [Elix. Euphorb. Comp.]

Antiasthmatic Elixir.

Each fluidrachm of this contains 3 minims of fluidextract of euphorbia, 0.4 minims of fluidextract of lobelia, 2 grains each of sodium bromide and iodide and 0.5 minim of spirit of nitroglycerine.

Dose, from one to two fluidrachms (4–8 cc.).

ELIXIR FERRI PYROPHOSPHATIS, QUININÆ ET STRYCHNINÆ. N. F.

Elixir of Ferric Pyrophosphate, Quinine and Strychnine [Elix. Ferr. Pyrophos., Quin. et Strych.]

This elixir differs from the formerly official elixir of iron, quinine and strychnine phosphates in containing soluble ferric pyrophosphate instead of phosphate, while the quinine in the former elixir is replaced by quinine sulphate. It contains 1–125th grain of strychnine, ½ grain of quinine sulphate, and 2 grains of soluble ferric pyrophosphate in 1 fluidrachm of finished elixir.

The *dose* is one to three fluidrachms (4–11 cc.).

ELIXIR FERRI, QUININÆ ET STRYCHNINÆ. N. F.

Elixir of Iron, Quinine and Strychnine [Elix. Ferr., Quin. et Strych.]

Elixir Triplex.

This elixir contains about 1 grain of ferric chloride, ½ grain quinine hydrochloride, and 1–100th grain of strychnine sulphate in 1 fluidrachm of finished elixir. It is used as a chalybeate tonic.

The *dose* is one to two fluidrachms (4–8 cc.).

ELIXIR GENTIANÆ. N. F.

Elixir of Gentian [Elix. Gent.]

It is made from fluidextract of gentian and is flavored with compound spirit of cardamom, but instead of being detannated by the ferric hydroxide process, compatibility with iron is achieved by the use of sodium citrate as an ingredient. It contains too small an amount of gentian to be therapeutically efficient. It is, however, often of service as a vehicle.

The *dose* is one to four fluidrachms (4–15 cc.).

ELIXIR GENTIANÆ ET FERRI. N. F. Elixir Gentianæ cum Tinctura Ferri Chloridi, N. F. III

Elixir of Gentian and Iron [Elix. Gent. et Ferr.]

Elixir of Gentian with Tincture of Ferric Citro-chloride.

Tincture of Citro-chloride of Iron, N. F., is used in this preparation along with the simple elixir of gentian. It represents ¾ of a grain of ferric chloride and nearly 2 grains of gentian in 1 fluidrachm. It is used as a bitter tonic.

The *dose* is one to four fluidrachms (4–15 cc.).

ELIXIR GENTIANÆ ET FERRI PHOSPHATIS. N. F.

Elixir of Gentian and Ferric Phosphate [Elix. Gent. et Ferr. Phosph.]

Elixir Gentianæ Ferratum.

This elixir represents 1 grain of soluble ferric phosphate and about 2 grains of gentian in 1 fluidrachm of the finished elixir. It is used as a chalybeate and tonic.

The *dose* is one to four fluidrachms (4–15 cc.).

ELIXIR GENTIANÆ GLYCERINATUM. N. F.

Glycerinated Elixir of Gentian [Elix. Gent. Glycerin.]

It contains small amounts of gentian and taraxacum in a sweetened and flavored sherry wine. The last is its most active ingredient.

The *dose* is two to four fluidrachms (8–15 cc.).

ELIXIR GLYCEROPHOSPHATUM COMPOSITUM. N. F.

Compound Elixir of Glycerophosphates [Elix. Glycerophos. Co.]

Compound Solution of Glycerophosphates.

This new elixir contains the glycerophosphates of sodium, calcium, iron, manganese with quinine, and strychnine. It represents about 2½ grains of combined glycerophosphates, 1–160th grain of strychnine and 1–20th grain of quinine in each fluidrachm.

The *dose* is two to four fluidrachms (8–15 cc.).

ELIXIR GLYCYRRHIZÆ AQUOSUM. N. F.

Aqueous Elixir of Glycyrrhiza [Elix. Glycyrrh. Aq.]

Aqueous Elixir of Licorice.

This is a new non-alcoholic flavoring elixir containing fluidextract of licorice, compound spirit of cardamom, and orange flower water as the principal ingredients.

ELIXIR GUARANÆ. N. F.

Elixir of Guarana [Elix. Guar.]

This elixir is made from fluidextract of guarana, aromatic elixir and compound elixir of taraxacum. About 12 grains of guarana are represented in 1 fluidrachm of finished elixir. Its effects are similar to those of caffeine.

The *dose* is one to four fluidrachms (4–15 cc.).

ELIXIR GUARANÆ ET APII. N. F.

Elixir of Guarana and Celery [Elix. Guaran. et Apii.]

This represents in each fluidrachm 18 minims each of the fluidextracts of guarana and celery.

Dose, two to four fluidrachms (8–15 cc.).

ELIXIR HELONIADIS COMPOSITUM. N. F.

Compound Elixir of Helonias [Elix. Heloniad. Co.]

This contains in each fluidrachm $1^{4}/_{5}$ minims each of fluidextracts of helonias, caulophyllum and viburnum opulus and $7^{1}/_{5}$ minims of mitchella. It is used in dysmenorrhea.

Dose, one to four fluidrachms (4–15 cc.).

ELIXIR HYDRANGEÆ ET LITHII. N. F.

Elixir of Hydrangea and Lithium [Elix. Hydrang. et Lith.]

Each fluidrachm of this elixir represents 24 grains of hydrangea, and 1½ grains each of lithium benzoate and salicylate.

Dose, one to four fluidrachms (4–15 cc.).

ELIXIR HYDRASTIS COMPOSITUM. N. F.

Compound Elixir of Hydrastis [Elix. Hydrast. Co.]

Alkaline Elixir.

This contains in each fluidrachm 1 minim of the fluidextracts of hydrastis, oats and xanthoxylum with traces of ginger, gentian and sodium bicarbonate. The most active ingredient is the alcohol.

Dose, one to four fluidrachms (4–15 cc.).

ELIXIR MANACÆ COMPOSITUM. N. F.

Compound Elixir of Manaca [Elix. Manac. Co.]

Each fluidrachm of this elixir represents 9½ grains of manaca and 13 grains of combined salicylates (sodium, potassium, and lithium). It is intended for cases of rheumatism.

Dose, one fluidrachm (4 cc.).

ELIXIR PEPSINI. N. F.

Elixir of Pepsin [Elix. Pepsin.]

This elixir is made from the glycerite of pepsin, hydrochloric acid and aromatic elixir. It represents about 1 grain of pepsin in 1 fluidrachm of finished preparation. It is improbable the pepsin retains its enzymic activity in the presence of so much alcohol as is in this elixir. It affords, however, a useful vehicle for certain salts, as the iodides or bromides.

The *dose* is two to four fluidrachms (8–15 cc.).

ELIXIR PEPSINI, BISMUTHI ET STRYCHNINÆ. N. F.

Elixir of Pepsin, Bismuth and Strychnine [Elix. Pepsin., Bism. et Strych.]

This elixir contains 1–100th of a grain of strychnine, ½ grain of pepsin and 7½ minims of glycerite of bismuth in 1 fluidrachm of finished preparation. It is an irrational combination.

The *dose* is one to three fluidrachms (4–11 cc.).

ELIXIR PEPSINI COMPOSITUM. N. F.

Compound Elixir of Pepsin [Elix. Pepsin. Co.]

Compound Digestive Elixir.

The most important differences between this and the simple elixir of pepsin are the color and flavor. It is a pleasant vehicle.

ELIXIR PEPSINI ET BISMUTHI. N. F.

Elixir of Pepsin and Bismuth [Elix. Pepsin. et Bism.]

This elixir contains about ½ grain of pepsin and 7½ minims of glycerite of bismuth in 1 fluidrachm of finished preparation.
The *dose* is two fluidrachms (8 cc.).

ELIXIR PEPSINI ET RENNINI COMPOSITUM. N. F.

Compound Elixir of Pepsin and Rennin [Elix. Pepsin. et Rennin. Co.]

Essentia Pepsini; Essence of Pepsin.

This elixir contains pepsin, rennin, and lactic acid. It is used chiefly as a vehicle.
The *dose* is two fluidrachms (8 cc.).

ELIXIR PHOSPHORI. N. F.

Elixir of Phosphorus [Elix. Phosphor.]

This elixir contains 1–64th of a grain of phosphorus in 1 fluidrachm of the finished preparation, and is flavored with compound spirit of orange and oil of anise. It affords an elegant and efficacious mode of exhibiting this remedy.
The *dose* is one-half to one fluidrachm (2–4 cc.).

ELIXIR PHOSPHORI ET NUCIS VOMICÆ. N. F.

Elixir of Phosphorus and Nux Vomica [Elix. Phosphor. et Nuc. Vom.]

About 2 minims of tincture of nux vomica and about 1–64th of a grain of phosphorus are represented in 1 fluidrachm of the finished elixir.
The *dose* is one-half to one fluidrachm (2–4 cc.).

ELIXIR POTASSII BROMIDI. N. F.

Elixir of Potassium Bromide [Elix. Pot. Brom.]

This elixir contains about 10 grains of potassium bromide in 1 fluidrachm of the finished preparation, and is used as a nerve sedative. Preparations of this type are better left to extemporaneous prescription.
The *dose* is one to two fluidrachms (4–8 cc.).

ELIXIR SABAL ET SANTALI COMPOSITUM. N. F.

Compound Elixir of Sabal and Sandalwood [Elix. Sabal et Santal. Co.]

Compound Elixir of Saw Palmetto and Sandalwood.

This represents in each fluidrachm 15 grains each of sabal, triticum, and corn-silk, with 4 minims of fluidextract of sandalwood. It is used in cystitis.
Dose, one to two fluidrachms (4–8 cc.).

ELIXIR SODII BROMIDI. N. F.

Elixir of Sodium Bromide [Elix. Sod. Brom.]

About 10 grains of sodium bromide are represented in 1 fluidrachm of finished elixir.
The *dose* is one to two fluidrachms (4–8 cc.).

ELIXIR SODII SALICYLATIS. N. F.

Elixir of Sodium Salicylate [Elix. Sod. Sal.]

Five grains of sodium salicylate are represented in 1 fluidrachm of the finished elixir. It is intended for an antirheumatic but is not a very happy combination.
The *dose* is one to three fluidrachms (4–11 cc.).

ELIXIR SODII SALICYLATIS COMPOSITUM. N. F.

Compound Elixir of Sodium Salicylate [Elix. Sod. Sal. Co.]

This new elixir contains in each fluidrachm about five grains of sodium salicylate, and one grain of potassium iodide with nearly one minim of fluidextract of gelsemium and two of cimicifuga. Such polypharmaceutical mixtures had better been left to extemporaneous prescription.
The *dose* is one to two fluidrachms (4–8 cc.).

ELIXIR TARAXACI COMPOSITUM. N. F.

Compound Elixir of Taraxacum [Elix. Tarax. Co.]

This elixir is made from fluidextracts of taraxacum, wild cherry and glycyrrhiza, with the tinctures of sweet orange peel and cinnamon, compound tincture of cardamom and aromatic elixir. It is used mainly as a vehicle to cover the taste of bitter substances.
The *dose* is two fluidrachms (8 cc.).

ELIXIR TERPINI HYDRATIS. N. F.

Elixir of Terpin Hydrate [Elix. Terpin. Hyd.]

This elixir contains terpin hydrate, tincture of sweet orange peel, spirit of bitter almond, alcohol, glycerin, and syrup. About 1 grain of terpin hydrate is contained in 1 fluidrachm of the finished preparation.
The *dose* is one to four fluidrachms (4–15 cc.).

ELIXIR TERPINI HYDRATIS ET CODEINÆ. N. F.

Elixir of Terpin Hydrate and Codeine [Elix. Terpin. Hyd. et Codein.]

This elixir contains about 1 grain of terpin hydrate and about ⅛ grain of codeine in 1 fluidrachm of the finished preparation. It is a much misused mixture.
The *dose* is one to four fluidrachms (4–15 cc.).

ELIXIR TERPINI HYDRATIS ET CREOSOTI COMPOSITUM. N. F.

Compound Elixir of Terpin Hydrate and Creosote [Elix. Terpin. Hyd. et Creosot. Co.]

Each fluidrachm represents ¼ grain of terpin hydrate, ¼ minim of creosote and ½ grain each of the glycerophosphates of calcium and sodium. These proportions are so small that a fluidounce of the elixir would contain scarcely a therapeutic dose. It contains 20 per cent. of alcohol.
The official *dose* is given as one fluidrachm (4 cc.), which is ridiculous.

ELIXIR TONGÆ ET SALICYLATUM. N. F.

Elixir of Tonga and Salicylates [Elix. Tong. et Salicyl.]

This is an imitation of a widely advertised proprietary nostrum. Each fluidrachm represents 8 grains of tonga, 2 of cimicifuga, 4 of sodium salicylate, 1–100th of pilocarpine nitrate and 1–500th of colchicine. It is intended for cases of chronic rheumatism and is the type of " shot-gun " that was more popular a generation ago.

Dose, one to three fluidrachms (4–11 cc.).

ELIXIR VANILLINI COMPOSITUM. N. F.

Compound Elixir of Vanillin [Elix. Vanil. Co.]

This new elixir, intended for a palatable vehicle, contains compound spirit of vanillin and is colored with tincture of caramel.

ELIXIR VIBURNI OPULI COMPOSITUM. N. F.

Compound Elixir of Viburnum Opulus [Elix. Viburn. Opul. Co.]

About 5 grains each of viburnum opulus and aletris and 10 grains of trillium with compound elixir of taraxacum are represented in 1 fluidrachm of the finished elixir. It is probably destitute of therapeutic virtues.

The *dose* is one to four fluidrachms (4–15 cc.).

ELIXIR VIBURNI PRUNIFOLII. N. F.

Elixir of Viburnum Prunifolium [Elix. Viburn. Prun.]

Elixir of Black Haw.

This elixir is made from fluidextract of viburnum prunifolium, compound tincture of cardamom, and aromatic elixir, and contains about 7½ grains of viburnum prunifolium in 1 fluidrachm of the finished preparation.

The *dose* is one to four fluidrachms (4–15 cc.).

EMPLASTRUM FUSCUM CAMPHORATUM. N. F.

Camphorated Brown Plaster [Emp. Fusc. Camph.]

Camphorated Mother Plaster.

This plaster is made from red oxide of lead, olive oil, yellow wax and camphor, and is used as a protective in inflamed conditions of the skin or subcutaneous tissues.

EMPLASTRUM SAPONIS. N. F.

Soap Plaster [Emp. Sapon.]

This is merely lead plaster with 10 per cent. of dried soap incorporated with it by the aid of a little water. The formula of the U. S. VIII is used, unchanged.

EMULSA. N. F.

Emulsions

In the National Formulary preference is given to acacia as the emulsifying agent, although other emulsifying agents are not ignored, as exemplified in the preparation of the numerous emulsions of cod liver oil. It is recommended that emulsions, being prone to deteriorate on standing, should be freshly prepared when needed. The following flavoring agents are suggested as being acceptable for cod liver oil, the choice being left to the prescriber:

a.	Oil of Betula	4	cc.
b.	Oil of Betula	2	cc.
	Oil of Sassafras	2	cc.
c.	Compound Spirit of Orange	1.5	cc.
d.	Oil of Betula	2	cc.
	Oil of Bitter Almond	0.25	cc.
	Oil of Coriander	0.25	cc.
e.	Oil of Betula	1.50	cc.
	Oil of Sassafras	1.50	cc.
	Oil of Bitter Almond	0.25	cc.
f.	Oil of Betula	2.5	cc.
	Oil of Bitter Almond	2.5	cc.

EMULSUM OLEI MORRHUÆ CUM HYPOPHOSPHITIBUS. N. F.

Emulsion of Cod Liver Oil with Hypophosphites [Emul. Ol. Morrh. c. Hypophos.]

This emulsion contains 50 per cent. of cod liver oil. Each dessertspoonful contains 1½ grains of calcium hypophosphite and ¾ grain each of sodium and potassium hypophosphites with sufficient flavoring.

The *dose* is two to four fluidrachms (8–15 cc.).

EMULSUM OLEI MORRHUÆ CUM MALTO. N. F.

Emulsion of Cod Liver Oil with Malt [Emul. Ol. Morrh. c. Malt.]

This emulsion contains 30 per cent. of cod liver oil with about 55 per cent. of extract of malt. It affords one of the most acceptable preparations of cod liver oil.

The *dose* is four fluidrachms (15 cc.).

EMULSUM OLEI MORRHUÆ CUM VITELLO. N. F.

Emulsion of Cod Liver Oil with Egg [Emul. Ol. Morrh. c. Vitel.]

This emulsion contains 50 per cent. cod liver oil with glycerite of yolk of egg, syrup of tolu and flavoring. It is used as a tonic.

The *dose* is four fluidrachms (15 cc.).

EMULSUM OLEI RICINI. N. F.

Emulsion of Castor Oil [Emul. Ol. Ricin.]

This emulsion contains 35 per cent. of castor oil, with tincture of vanilla, syrup and water. It is used as a cathartic.

The *dose* is one and one-half fluidounces (45 cc.).

EMULSUM PETROLATI. N. F. Emulsum Petrolei, N. F. III

Emulsion of Petrolatum [Emul. Petrolat.]

This emulsion contains about 22.5 per cent. each, of white petrolatum, and expressed oil of almond, with acacia, tragacanth and syrup, tincture of lemon peel and water.

The *dose* is one-half to one fluidounce (8–15 cc.).

EXTRACTUM CONII. N. F.

Extract of Conium [Ext. Conii.]

Extract of conium yields not less than 1.8 per cent. nor more than 2.2 per cent. of coniine. This extract is prepared with diluted alcohol, a small quantity of diluted hydrochloric acid being added previous to the evaporation of the percolate. An assay is provided.

The *dose* is one-half grain (0.03 Gm.).

EXTRACTUM ERGOTÆ AQUOSUM. N. F.

Aqueous Extract of Ergot [Ext. Ergot. Aq.]

Ergotin, *P. I.*

This extract is prepared by percolating the powdered ergot, using chloroform water as menstruum, reducing to proper consistency by means of careful heat, and adding an equal weight of alcohol, and after allowing it to stand for three days, it is then filtered and the filtrate reduced to a pilular consistence. For reasons pointed out elsewhere (see *Ergota*, Part I) it does not represent the therapeutic virtues of ergot.

The *dose* is three grains (0.2 Gm.).

EXTRACTUM EUONYMI. N. F.

Extract of Euonymus [Ext. Euonymi]

Powdered Extract of Euonymus.

One gramme of the extract represents four grammes of euonymus. It is prepared by exhausting the powdered drug with diluted alcohol, evaporating to dryness, and diluting with starch.

"Caution.—It has been stated that the absorption of euonymus in the gastro-intestinal tract is uncertain and irregular. To avoid possible toxic or cumulative action, the physician should carefully guard the dosage and determine in each case the tolerance of the patient and regulate the dosage accordingly." *N. F.*

The *dose* is two grains (0.125 Gm.).

EXTRACTUM FERRI POMATUM. N. F.

Ferrated Extract of Apples [Ext. Ferr. Pomat.]

Ferri Malas Crudus; Crude Malate of Iron.

This extract is made from iron wire, fresh apple juice and water, and is used as a chalybeate.

The *dose* is ten grains (0.65 Gm.).

EXTRACTUM GENTIANÆ. N. F.

Extract of Gentian [Ext. Gentian.]

This is made by percolating with water and evaporating to dryness. It is used as a bitter stomachic. The practice of employing this extract as a pill mass is to be deprecated as it is not medicinally inert.

Dose, two to five grains (0.12–0.3 Gm.).

EXTRACTUM HÆMATOXYLI. N. F.

Extract of Hematoxylon [Ext. Hæmatox.]

This extract is prepared by exhausting the rasped drug with boiling water and evaporating the extract to dryness.

The *dose* is ten to thirty grains (0.6–2.0 Gm.).

EXTRACTUM HYDRASTIS. N. F.

Extract of Hydrastis [Ext. Hydrast.]

Powdered Extract of Hydrastis; Extract of Golden Seal.

It is made with a menstruum of alcohol acidulated with tartaric acid and "yields not less than 9 per cent. nor more than 11 per cent. of ether soluble alkaloids."

Dose, five to ten grains (0.3–0.6 Gm.).

EXTRACTUM IGNATIÆ. N. F.

Extract of Ignatia [Ext. Ignat.]

Powdered Extract of Ignatia.

Extract of ignatia yields not less than 5.4 per cent. nor more than 6.6 per cent. of the combined alkaloids of ignatia. It is prepared by exhausting the powdered drug with 75 per cent. alcohol, evaporating to dryness, weighing, and assaying at this stage, and finally diluting to the proper standard with starch.

The *dose* is one-fourth to three-fourths of a grain (0.015–0.045 Gm.).

EXTRACTUM KRAMERIÆ. N. F.

Extract of Krameria [Ext. Kramer.]

Powdered Extract of Krameria.

One gramme of the extract represents four grammes of krameria. It is prepared by exhausting the powdered drug with cold water. The percolate is then heated to boiling, strained, and the strained liquid evaporated to dryness and sufficient dried starch added as diluent.

The *dose* is five to ten grains (0.3–0.6 Gm.).

EXTRACTUM LEPTANDRÆ. N. F.

Extract of Leptandra [Ext. Leptand.]

Powdered Extract of Leptandra.

One gramme of the extract represents four grammes of leptandra. It is prepared by exhausting the drug with a menstruum of 75 per cent. alcohol, evaporating the percolate to dryness and diluting with dried starch.

The *dose* is from five to ten grains (0.3–0.6 Gm.).

EXTRACTUM OPII. N. F.

Extract of Opium [Ext. Opii]

Powdered Extract of Opium; Opii Extractum, *P. I.*

"Extract of Opium yields not less than 19.5 per cent. and not more than 20.5 per cent. of anhydrous morphine. One Gm. of the extract represents about 2 Gm. of Opium." *N. F.* This preparation does not differ materially from the extract of opium of the U. S. IX. (See also *Extractum Opii Siccum*, Part I.)

Dose, from one-sixth to one grain (0.01–0.06 Gm.).

EXTRACTUM SUMBUL. N. F.

Extract of Sumbul [Ext. Sumbul]

The formula for this preparation is the same as that of the U. S. IX.

The *dose* is from two to five grains (0.12–0.30 Gm.).

EXTRACTUM TARAXACI. N. F.

Extract of Taraxacum [Ext. Tarax.]

This preparation is the same as that formerly recognized by the U. S. IX under the same title.

The *dose* is from fifteen to sixty grains (1–4 Gm.).

FERRI OXIDUM SACCHARATUM. N. F.

Saccharated Ferric Oxide [Ferr. Oxid. Sacch.]

Soluble Ferric Oxide; Ferrum Oxydatum Saccharatum; Eisenzucker, *G.*

Saccharated ferric oxide contains the equivalent of not less than 2.8 per cent. of Fe. In the preparation of this product, freshly precipitated ferric hydroxide is dissolved in a heavy sugar syrup by the addition of a small quantity of sodium hydroxide. This solution is then evaporated on a water bath and enough sugar added to bring it to the desired weight. An assay process is given.

Dose, thirty grains (2 Gm.).

FLUIDEXTRACTA. N. F.

Fluidextracts

The fluidextracts of the N. F., like those of the U. S. P., are mostly made according to one of four type processes. These processes are essentially the same as those of the U. S. P. (see Part I). Fluidextracts should be stored in amber-colored bottles protected from sunlight and extremes of temperature. (See also *Fluidextracta*, Part I.)

FLUIDEXTRACTUM ACONITI. N. F.

Fluidextract of Aconite [Fldext. Aconit.]

This is made with a menstruum of three volumes of alcohol and one volume of water. " When assayed biologically, the minimal lethal dose of Fluidextract of Aconite should be not greater than 0.00004 cc. for each Gm. of body weight of guinea-pig." *N. F.* For description of the method of assay see under *Aconitum*, Part I.

The use of this preparation is not to be recommended because it is so highly toxic that slight errors in dosage or manipulation may have serious effects.

The *dose* is one minim (0.06 cc.).

FLUIDEXTRACTUM ADONIDIS. N. F.

Fluidextract of Adonis [Fldext. Adonid.]

Prepared by using three volumes of alcohol and one volume of water as the menstruum.

The *dose* is two to five minims (0.12–0.30 cc.).

FLUIDEXTRACTUM ALETRIDIS. N. F.

Fluidextract of Aletris [Fldext. Aletrid.]

Prepared by using diluted alcohol as the menstruum.

The *dose* is thirty to sixty minims (2–4 cc.).

FLUIDEXTRACTUM ANGELICÆ RADICIS. N. F.

Fluidextract of Angelica Root [Fldext. Angel. Rad.]

Prepared by using 5 volumes of alcohol with one of water as the menstruum.

The *dose* is thirty to sixty minims (2–4 cc.).

FLUIDEXTRACTUM APII FRUCTUS. N. F.

Fluidextract of Celery Fruit [Fldext. Apii Fruct.]

Prepared by using alcohol as the menstruum. In order to remove any separated oil, after permitting the fluidextract to stand, filter it through an alcohol-wetted filter, rejecting the final few cc. remaining on the filter with the oil.

The *dose* is from twenty to sixty minims (1.3–4 cc.).

FLUIDEXTRACTUM APOCYNI. N. F.

Fluidextract of Apocynum [Fldext. Apocyn.]

Prepared by using three volumes of water as menstruum I, and three volumes of alcohol and two volumes of water as menstruum II. It may be assayed by the method described under *Digitalis* (Part I). The increase in the proportion of alcohol, over that of the U. S. VIII, is an advantage.

" CAUTION.—It has been stated that the absorption of apocynum in the gastro-intestinal tract is uncertain and irregular. To avoid an accumulation of the drug or toxic action, the physician should carefully guard the dosage and determine in each case the tolerance of the patient." *N. F.*

The *dose* is from five to fifteen minims (0.3–1.0 cc.).

FLUIDEXTRACTUM ARALIÆ. N. F.

Fluidextract of Aralia [Fldext. Aral.]

Prepared by using two volumes of alcohol and one volume of water as the menstruum. It is used as an alterative.

The *dose* is thirty minims (2 cc.).

FLUIDEXTRACTUM ARNICÆ. N. F. Fluidextractum Arnicæ Florum, N. F. III

Fluidextract of Arnica [Fldext. Arnic.]

Prepared by using two volumes of alcohol with one of water as the menstruum.

The *dose* is from one to three minims (0.06–0.2 cc.).

FLUIDEXTRACTUM ASCLEPIADIS. N. F.

Fluidextract of Asclepias [Fldext. Asclepiad.]

Prepared by using diluted alcohol as the menstruum. It is used as a diaphoretic, emetic, and cathartic.

The *dose* is from twenty to sixty minims (1.2–4.0 cc.).

FLUIDEXTRACTUM AVENÆ SATIVÆ. N. F.

Fluidextract of Avena Sativa [Fldext. Aven. Sativ.]

This is prepared with a menstruum consisting of two volumes of alcohol and one of water.

The official *dose* is one fluidrachm (4 cc.) but larger amounts can be safely given.

FLUIDEXTRACTUM BAPTISIÆ. N. F.

Fluidextract of Baptisia [Fldext. Baptis.]

Prepared by using three volumes of alcohol and one volume of water as the menstruum.

The *dose* is fifteen minims (1 cc.)

FLUIDEXTRACTUM BERBERIDIS. N. F.

Fluidextract of Berberis [Fldext. Berberid.]

Prepared by using diluted alcohol as the menstruum. It is used as an astringent tonic and cathartic.

The *dose* is from ten to thirty minims (0.6–2 cc.).

FLUIDEXTRACTUM BOLDI. N. F.

Fluidextract of Boldo [Fldext. Boldi]

Prepared by using alcohol as the menstruum. It is used as an alterative and tonic.

The *dose* is from five to eight minims (0.3–0.5 cc.).

FLUIDEXTRACTUM BUCHU COMPOSITUM. N. F.

Compound Fluidextract of Buchu [Fldext. Buchu Co.]

Prepared by using four volumes of alcohol and one volume of water as the menstruum. Each fluidrachm represents 37½ grains of buchu and 7½ grains each of cubeb, juniper and uva ursi.

The *dose* is from thirty to sixty minims (2–4 cc.).

FLUIDEXTRACTUM CALENDULÆ. N. F.

Fluidextract of Calendula [Fldext. Calend.]

Prepared by using two volumes of alcohol with one of water as the menstruum.

Dose, (official) fifteen minims (1 cc.).

FLUIDEXTRACTUM CALUMBÆ. N. F.

Fluidextract of Calumba [Fldext. Calumb.]

Prepared by using one volume of glycerin, two volumes of alcohol, and one volume of water as menstruum.

The *dose* is from ten to thirty minims (0.6–2.0 cc.).

FLUIDEXTRACTUM CASTANEÆ. N. F.

Fluidextract of Chestnut Leaves [Fldext. Castan.]

Prepared by using boiling water as the menstruum and adding ten volumes of glycerin and twenty volumes of alcohol being added as a preservative. It is used as an astringent.

The *dose* is from thirty to sixty minims (2–4 cc.).

FLUIDEXTRACTUM CATARIÆ. N. F.

Fluidextract of Catnep [Fldext. Catar.]

Prepared by using three volumes of alcohol and four volumes of water as the menstruum.

The *dose* is from one-half to one fluidrachm (2–4 cc.).

FLUIDEXTRACTUM CAULOPHYLLI. N. F.

Fluidextract of Caulophyllum [Fldext. Caulophyl.]

Prepared by using three volumes of alcohol and one volume of water as the menstruum.

The *dose* is from five to ten minims (0.3–0.6 cc.).

FLUIDEXTRACTUM CHIMAPHILÆ. N. F.

Fluidextract of Chimaphila [Fldext. Chimaphil.]

Prepared by using diluted alcohol as the menstruum. It is used chiefly for its effects on the mucous membrane of the bladder and urethra.

The *dose* is thirty to sixty minims (2–4 cc.).

FLUIDEXTRACTUM CHIONANTHI. N. F.

Fluidextract of Chionanthus [Fldext. Chionanth.]

Prepared by using three volumes of alcohol and one volume of water as the menstruum.

The *dose* is thirty to sixty minims (2–4 cc.).

FLUIDEXTRACTUM CHIRATÆ. N. F.

Fluidextract of Chirata [Fldext. Chirat.]

Prepared by using diluted alcohol as the menstruum. It is used as a tonic and febrifuge.

The *dose* is from ten to twenty minims (0.6–1.2 cc.).

FLUIDEXTRACTUM COCILLANÆ. N. F.

Fluidextract of Cocillana [Fldext. Cocillan.]

Prepared by using three volumes of alcohol and one volume of water as the menstruum.

The *dose* is from ten to twenty minims (0.6–1.2 cc.).

FLUIDEXTRACTUM COFFEÆ. N. F. Fluidextractum Coffeæ Tostæ, N. F. III

Fluidextract of Coffee [Fldext. Coff.]

Prepared by using 65 cc. of glycerin, 250 cc. of alcohol, and 685 cc. of water as menstruum I, and one volume of alcohol and three volumes of water as menstruum II.

The *dose* is thirty to sixty minims (2–4 cc.).

FLUIDEXTRACTUM COLCHICI CORMI. N. F.

Fluidextract of Colchicum Corm [Fldext. Colch. Corm.]

"One hundred cc. of fluidextract of colchicum corm yields not less than 0.31 Gm. nor more than 0.39 Gm. of colchicine." *N. F.* Prepared by using a menstruum of two volumes of alcohol and one volume of water. After assaying adjust the volume of the finished product to conform with the required standard. An assay is provided in the text.

The *dose* is from two to eight minims (0.12–0.50 cc.).

FLUIDEXTRACTUM CONDURANGO. N. F.

Fluidextract of Condurango [Fldext. Condurango]

Prepared by using diluted alcohol as the menstruum. It is used as an alterative and stomachic.

The *dose* is one fluidrachm (4 cc.).

FLUIDEXTRACTUM CONVALLARIÆ RADICIS. N. F.

Fluidextract of Convallaria Root [Fldext. Conval. Rad.]

Prepared by using three volumes of alcohol and one volume of water as the menstruum.

The *dose* is from five to ten minims (0.3–0.6 cc.).

FLUIDEXTRACTUM COPTIS. N. F.

Fluidextract of Coptis [Fldext. Copt.]

Prepared by using diluted alcohol as the menstruum.

The *dose* is thirty minims (2 cc.).

FLUIDEXTRACTUM CORNI. N. F. Fluidextractum Cornus, N. F. III

Fluidextract of Cornus [Fldext. Corni]

Prepared by using 150 cc. of glycerin and 850 cc. of diluted alcohol as menstruum I, and diluted alcohol as menstruum II.

The *dose* is from thirty to sixty minims (2–4 cc.).

FLUIDEXTRACTUM CORYDALIS. N. F.

Fluidextract of Corydalis [Fldext. Corydal.]

Prepared by using three volumes of alcohol and one volume of water as the menstruum.

The *dose* is from ten to twenty minims (0.6–1.2 cc.).

FLUIDEXTRACTUM CUBEBÆ. N. F.

Fluidextract of Cubeb [Fldext. Cubeb.]

Prepared by using alcohol as the menstruum.

The *dose* is from fifteen to thirty minims (1–2 cc.).

FLUIDEXTRACTUM CYPRIPEDII. N. F.

Fluidextract of Cypripedium [Fldext. Cypriped.]

Prepared by using diluted alcohol as the menstruum.

The *dose* is from fifteen to thirty minims (1–2 cc.).

FLUIDEXTRACTUM DAMIANÆ. N. F.
Fluidextractum Turneræ, N. F. III

Fluidextract of Damiana [Fldext. Damian.]

Prepared by using three volumes of alcohol and one volume of water as the menstruum. It is attributed, but probably erroneously so, with aphrodisiac powers.

The *dose* is from one-half to one fluidrachm (2–4 cc.).

FLUIDEXTRACTUM DIGITALIS. N. F.

Fluidextract of Digitalis [Fldext. Digit.]

This is made with a menstruum consisting of five volumes of alcohol and one of water. "When assayed biologically the minimal lethal dose should not be greater than 0.0006 cc. of the Fluidextract, or the equivalent in Fluidextract of 0.000,000,5 Gm. of ouabain for each Gm. of body weight of frog." *N. F.* For method of assay see under *Tinctura Digitalis*, Part I.

The *dose* is from one-half to one and a half minims (0.03–0.10 cc.).

FLUIDEXTRACTUM DIOSCOREÆ. N. F.

Fluidextract of Dioscorea [Fldext. Dioscor.]

Prepared by using diluted alcohol as the menstruum.

The *dose* is one fluidrachm (4 cc.).

FLUIDEXTRACTUM DROSERÆ. N. F.

Fluidextract of Drosera [Fldext. Droser.]

Prepared by using two volumes of alcohol and one volume of water as the menstruum.

The *dose* is from one-half to one fluidrachm (2–4 cc.).

FLUIDEXTRACTUM DULCAMARÆ. N. F.

Fluidextract of Bittersweet [Fldext. Dulcam.]

Prepared by using diluted alcohol as the menstruum.

The *dose* is from one-half to one fluidrachm (2–4 cc.).

FLUIDEXTRACTUM ECHINACEÆ. N. F.

Fluidextract of Echinacea [Fldext. Echin.]

Prepared by using four volumes of alcohol and one volume of water as the menstruum.

The *dose* is from ten to thirty minims (0.6–2.0 cc.).

FLUIDEXTRACTUM EUONYMI. N. F.

Fluidextract of Euonymus [Fldext. Euonym.]

Prepared by using diluted alcohol and one volume of water as the menstruum.

The *dose* is eight minims (0.5 cc.).

"CAUTION.—It has been stated that the absorption of euonymus in the gastro-intestinal tract is uncertain and irregular. To avoid possible toxic or cumulative action of the drug, the physician should carefully determine in each case the tolerance of the patient and regulate the dosage accordingly." *N. F.*

Dose, five to ten minims (0.3–1.2 cc.).

FLUIDEXTRACTUM EUPATORII. N. F.

Fluidextract of Eupatorium [Fldext. Eupator.]

Prepared by using diluted alcohol as a menstruum.

The *dose* is thirty minims (2 cc.).

FLUIDEXTRACTUM EUPHORBIÆ. N. F.

Fluidextract of Euphorbia [Fldext. Euphorb. Pilul.]

Prepared by using diluted alcohol as the menstruum. The change of name (formerly it was *Fluidextractum Euphorbiæ Piluliferæ*) is, in our opinion, unfortunate as other species of Euphorbia—with very different medicinal properties—are used in medicine.

The *dose* is thirty minims (2 cc.).

FLUIDEXTRACTUM FRANGULÆ. N. F.

Fluidextract of Frangula [Fldext. Frang.]

In this preparation water is used as the extracting menstruum but 25 per cent. of alcohol is added to the finished fluidextract as a preservative.

The *dose* is from ten to twenty minims (0.6–1.2 cc.).

FLUIDEXTRACTUM FUCI. N. F.

Fluidextract of Fucus [Fldext. Fuci]

Prepared by using three volumes of alcohol and one volume of water as the menstruum.

The *dose* is ten minims (0.6 cc.).

FLUIDEXTRACTUM GALEGÆ. N. F.

Fluidextract of Galega [Fldext. Galeg.]

Prepared by using diluted alcohol as the menstruum.

The *dose* is one fluidrachm (4 cc.).

FLUIDEXTRACTUM GELSEMII. N. F.

Fluidextract of Gelsemium [Fldext. Gelsem.]

Prepared with a menstruum of 4 volumes of alcohol and one of water.

Dose, from one-half to three minims (0.03–0.2 cc.).

FLUIDEXTRACTUM GENTIANÆ. N. F.

Fluidextract of Gentian [Fldext. Gentian.]

Made with a menstruum of diluted alcohol.

Dose, from ten to twenty minims (0.6–1.2 cc.).

FLUIDEXTRACTUM GERANII. N. F.

Fluidextract of Geranium [Fldext. Geran.]

Prepared by using one volume of glycerin, six volumes of alcohol and one volume of water as menstruum I, and three volumes of alcohol and two volumes of water as menstruum II. It is used as an astringent and styptic.

The *dose* is from fifteen to thirty minims (1–2 cc.).

FLUIDEXTRACTUM GOSSYPII CORTICIS. N. F.

Fluidextract of Cotton Root Bark [Fldext. Gossyp. Cort.]

Prepared by using alcohol as the menstruum.

The *dose* is from one-half to one fluidrachm (2–4 cc.).

FLUIDEXTRACTUM GRINDELIÆ. N. F.

Fluidextract of Grindelia [Fldext. Grindel.]

This is made with a menstruum of three volumes of alcohol and one volume of water.

The *dose* is from thirty to sixty minims (2–4 cc.).

FLUIDEXTRACTUM GUARANÆ. N. F.

Fluidextract of Guarana [Fldext. Guaran.]

"One hundred cc. of Fluidextract of Guarana yields not less than 3.6 Gm. and not more than 4.4 Gm. of anhydrous caffeine." *N. F.* It is made with a menstruum of three volumes of alcohol with one of water.

The *dose* is from thirty to sixty minims (2–4 cc.).

FLUIDEXTRACTUM HAMAMELIDIS FOLIORUM. N. F.

Fluidextract of Hamamelis Leaves [Fldext. Hamamel. Fol.]

Prepared by using one volume of glycerin, three volumes of alcohol, and five volumes of water as menstruum I, and one volume of alcohol and two volumes of water as menstruum II.

The *dose* is from fifteen to thirty minims (1–2 cc.).

FLUIDEXTRACTUM HELONIADIS. N. F.

Fluidextract of Helonias [Fldext. Helon.]

Prepared by using diluted alcohol as the menstruum.

The *dose* is thirty minims (2 cc.).

FLUIDEXTRACTUM HUMULI. N. F.

Fluidextract of Hops [Fldext. Humul.]

Prepared by using five volumes of alcohol and three volumes of water as the menstruum. It is used as a nerve sedative.

The *dose* is from one-half to one fluidrachm (2–4 cc.).

FLUIDEXTRACTUM HYDRANGEÆ. N. F.

Fluidextract of Hydrangea [Fldext. Hydrang.]

Prepared by using three volumes of alcohol and two volumes of water as the menstruum.

The *dose* is thirty minims (2 cc.).

FLUIDEXTRACTUM IRIDIS VERSICOLORIS. N. F.

Fluidextract of Blue Flag [Fldext. Iris Vers. Fluidextractum Iridis, N. F. III]

Prepared by using alcohol as the menstruum.

The *dose* is from ten to thirty minims (0.6–2 cc.).

FLUIDEXTRACTUM JALAPÆ. N. F.

Fluidextract of Jalap [Fldext. Jalap.]

Prepared by mixing the drug with clean sand and using alcohol as the menstruum. "One hundred cc. of Fluidextract of Jalap yields not less than 6.5 Gm. and not more than 7.5 Gm. of the resin of Jalap." *N. F.*

The *dose* is from ten to twenty minims (0.6–1.3 cc.).

FLUIDEXTRACTUM JUGLANDIS. N. F.

Fluidextract of Juglans [Fldext. Jugland.]

Prepared by using 100 cc. of glycerin, 500 cc. of alcohol and 400 cc. of water as menstruum I, and diluted alcohol as menstruum II. It is used as a cathartic.

The *dose* is from one-half to one fluidrachm (2–4 cc.).

FLUIDEXTRACTUM JUNIPERI. N. F.

Fluidextract of Juniper Berries [Fldext. Junip.]

Prepared by using four volumes of alcohol with one of water as the menstruum. It is used as a diuretic.

The *dose* is one fluidrachm (4 cc.).

FLUIDEXTRACTUM KAVÆ. N. F.

Fluidextract of Kava [Fldext. Kav.]

Prepared by using three volumes of alcohol and two volumes of water as the menstruum.

The *dose* is fifteen minims (1 cc.).

FLUIDEXTRACTUM KOLÆ. N. F.

Fluidextract of Kola [Fldext. Kol. Fluidextractum Sterculiæ, N. F. III]

Prepared by using two volumes of alcohol and one volume of water as the menstruum. "One hundred cc. of Fluidextract of Kola yields not less than 0.85 Gm. and not more than 1.15 Gm. of caffeine." *N. F.*

The *dose* is one fluidrachm (4 cc.).

FLUIDEXTRACTUM KRAMERIÆ. N. F.

Fluidextract of Krameria [Fldext. Kramer.]

Prepared by using one volume of glycerin, five volumes of alcohol and four volumes of water as menstruum I, and diluted alcohol as menstruum II.

The *dose* is from fifteen to forty-five minims (1–3 cc.).

FLUIDEXTRACTUM LAPPÆ. N. F.

Fluidextract of Lappa [Fldext. Lapp.]

Prepared by using diluted alcohol as the menstruum.

The *dose* is from thirty to sixty minims (2–4 cc.).

FLUIDEXTRACTUM LEPTANDRÆ. N. F.

Fluidextract of Leptandra [Fldext. Leptand.]

Prepared by using three volumes of alcohol and one volume of water as the menstruum.

The *dose* is from fifteen to thirty minims (1–2 cc.).

FLUIDEXTRACTUM LOBELIÆ. N. F.

Fluidextract of Lobelia [Fldext. Lobel.]

This is prepared with a mixture of 50 cc. of acetic acid, 500 cc. of alcohol and 450 cc. of water as menstruum I and diluted alcohol as menstruum II.

The *dose* is one to two minims (0.06–0.12 cc.).

FLUIDEXTRACTUM LUPULINI. N. F.

Fluidextract of Lupulin [Fldext. Lupulin.]

It is made with alcohol as the menstruum.

The *dose* is from five to ten minims (0.3–0.6 cc.).

FLUIDEXTRACTUM MANACÆ. N. F.

Fluidextract of Manaca [Fldext. Manac.]

This is prepared with a mixture of three volumes of alcohol and one of water as the menstruum.

The *dose* is from ten to thirty minims (0.6–1 cc.).

FLUIDEXTRACTUM MATICO. N. F.

Fluidextract of Matico [Fldext. Matic.]

Prepared by using three volumes of alcohol and one volume of water, as directed by the U. S. P. VIII, as the menstruum.

The *dose* is one fluidrachm (4 cc.).

FLUIDEXTRACTUM MEZEREI. N. F.

Fluidextract of Mezereum [Fldext. Mezer.]

Prepared by using three volumes of alcohol and one volume of water as the menstruum. It is used as a rubefacient.

FLUIDEXTRACTUM MITCHELLÆ. N. F.

Fluidextract of Mitchella [Fldext. Mitchel.]

This is prepared with diluted alcohol as the menstruum.

The *dose* is from thirty to sixty minims (2–4 cc.).

FLUIDEXTRACTUM NUCIS VOMICA. N. F.

Fluidextract of Nux Vomica [Fldext. Nuc. Vom.]

"One hundred cc. of Fluidextract of Nux Vomica yields not less than 2.37 Gm. and not more than 2.63 Gm. of the alkaloids of Nux Vomica." *N. F.* It is prepared with a menstruum of three volumes of alcohol with one of water.

The *dose* is from one to two minims (0.06–0.12 cc.).

FLUIDEXTRACTUM PAREIRÆ. N. F.

Fluidextract of Pareira [Fldext. Pareir.]

Prepared by using diluted alcohol as the menstruum.

The *dose* is from thirty to sixty minims (1–2 cc.).

FLUIDEXTRACTUM PHYTOLACCÆ. N. F.

Fluidextract of Phytolacca [Fldext. Phytolac.]

Prepared by using diluted alcohol, as the menstruum.

The *dose* is from ten to thirty minims (0.6–2.0 cc.) as an emetic, and one to five minims (0.06–0.30 cc.) as an alterative.

FLUIDEXTRACTUM PRUNI VIRGINIANÆ. N. F.

Fluidextract of Wild Cherry [Fldext. Prun. Virg.]

Prepared by using 200 cc. of glycerin and 400 cc. of water as the macerating menstruum, then percolating with a menstruum of 250 cc. of alcohol and 150 cc. of water and continuing with one volume of alcohol and three volumes of water as the menstruum.

The *dose* is one-half to one fluidrachm (2–4 cc.).

FLUIDEXTRACTUM QUASSIÆ. N. F.

Fluidextract of Quassia [Fldext. Quass.]

Prepared by using one volume of alcohol and two volumes of water, as the menstruum. This affords an excellent means of obtaining the effects of quassia. It has the advantage over the tincture of not requiring so large an amount of alcohol.

The *dose* is from five to fifteen minims (0.3–1.0 cc.).

FLUIDEXTRACTUM QUERCUS. N. F.

Fluidextract of Quercus [Fldext. Querc.]

Prepared by using 100 cc. of glycerin, 500 cc. of alcohol and 400 cc. of water as menstruum I, and diluted alcohol as menstruum II.

The official *dose* is fifteen minims (1 cc.) but it is rarely used internally.

FLUIDEXTRACTUM RHAMNI CATHARTICÆ. N. F.

Fluidextract of Rhamnus Cathartica [Fldext. Rham. Cathart.]

Prepared by using diluted alcohol as the menstruum.

The *dose* is fifteen minims (1 cc.).

FLUIDEXTRACTUM RUBI. N. F.

Fluidextract of Rubus [Fldext. Rubi]

Prepared by using diluted alcohol as the menstruum. It is used as an intestinal astringent.

The *dose* is from fifteen to thirty minims (1–2 cc.).

FLUIDEXTRACTUM RUMICIS. N. F.

Fluidextract of Rumex [Fldext. Rumic.]

Prepared by using diluted alcohol as the menstruum.

The *dose* is from fifteen to sixty minims (1–4 cc.).

FLUIDEXTRACTUM SABAL. N. F.

Fluidextract of Sabal [Fldext. Sabal]

Prepared with a menstruum of four volumes of alcohol with one of water.

The *dose* is from ten to twenty minims (0.6–1.2 cc.).

FLUIDEXTRACTUM SANGUINARIÆ. N. F.

Fluidextract of Sanguinaria [Fldext. Sanguin.]

Prepared by using 50 cc. of hydrochloric acid, 200 cc. of water and 750 cc. of alcohol as menstruum I, and three volumes of alcohol and one volume of water as menstruum II. The former process used citric, instead of hydrochloric, acid.

The *dose* is from one to five minims (0.06–0.3 cc.).

FLUIDEXTRACTUM SANTALI ALBI. N. F.

Fluidextract of Sandal Wood [Fldext. Santal. Alb.]

This is made with a menstruum of alcohol.

Dose, one fluidrachm (4 cc.).

FLUIDEXTRACTUM SARSAPARILLÆ COMPOSITUM. N. F.

Compound Fluidextract of Sarsaparilla [Fldext. Sarsap. Co.]

This is practically the same as the compound fluidextract of the U. S. IX and contains sarsaparilla, licorice, sassafras and mezereum. It is made with a mixture of 100 cc. of glycerin, 500 cc. of alcohol and 400 cc. of water as menstruum I and diluted alcohol as menstruum II.

The *dose* is from thirty to sixty minims (2–4 cc.).

FLUIDEXTRACTUM SCOPARII. N. F.

Fluidextract of Scoparius [Fldext. Scopar.]

Prepared by using diluted alcohol as the menstruum.

The *dose* is from ten to fifteen minims (0.6–1 cc.).

FLUIDEXTRACTUM SCUTELLARIÆ. N. F.

Fluidextract of Scutellaria [Fldext. Scutellar.]

Prepared by using diluted alcohol as the menstruum.

The *dose* is from fifteen minims to one fluidrachm (1–4 cc.).

FLUIDEXTRACTUM SENECIONIS. N. F.

Fluidextract of Senecio [Fldext. Senecion.]

Prepared by using two volumes of alcohol and one volume of water as the menstruum.

The *dose* is one fluidrachm (4 cc.).

FLUIDEXTRACTUM SERPENTARIÆ. N. F.

Fluidextract of Serpentaria [Fldext. Serpentar.]

Prepared by using four volumes of alcohol and one volume of water as the menstruum.

The *dose* is from fifteen to thirty minims (1–2 cc.).

FLUIDEXTRACTUM SOLANI. N. F.

Fluidextract of Solanum [Fldext. Solan.]

Prepared by using two volumes of alcohol and one volume of water as the menstruum.

The *dose* is one fluidrachm (4 cc.).

FLUIDEXTRACTUM STILLINGIA. N. F.

Fluidextract of Stillingia [Fldext. Stilling.]

This is made with a menstruum of diluted alcohol.

The *dose* is from fifteen to forty-five minims (1–3 cc.).

FLUIDEXTRACTUM STILLINGIÆ COMPOSITUM. N. F.

Compound Fluidextract of Stillingia [Fldext. Stilling. Co.]

Prepared by using diluted alcohol as the menstruum. It contains stillingia, corydalis, iris, sambucus, chimaphila, coriander, and xanthoxylum berries. It is a relic of therapeutic superstition.

The *dose* is from thirty to sixty minims (2–4 cc.).

FLUIDEXTRACTUM STRAMONII. N. F.

Fluidextract of Stramonium [Fldext. Stramon.]

"One hundred cc. of fluidextract of stramonium yields not less than 0.22 Gm. nor more than 0.28 Gm. of the alkaloids of stramonium." *N. F.* Prepared by using four volumes of alcohol and one volume of water as the menstruum. An assay is provided in the text.

The *dose* is one minim (0.05 cc.).

FLUIDEXTRACTUM TARAXACI. N. F.

Fluidextract of Taraxacum [Fldext. Tarax.]

Made with a menstruum of alcohol, water and glycerin.

Dose, from two to four fluidrachms (8–15 cc.).

FLUIDEXTRACTUM THUJÆ. N. F.

Fluidextract of Thuja [Fldext. Thuj.]

Prepared by using alcohol as the menstruum.

The *dose* is from fifteen to forty-five minims (1–3 cc.).

FLUIDEXTRACTUM THYMI. N. F.

Fluidextract of Thyme [Fldext. Thym.]

Prepared by using 100 cc. of glycerin, 250 cc. of alcohol and 650 cc. of water as menstruum I, and one volume of alcohol and three volumes of water as menstruum II.

The *dose* is from one-half to one fluidrachm (2–4 cc.).

FLUIDEXTRACTUM TONGÆ. N. F.

Fluidextract of Tonga [Fldext. Tong.]

This is prepared with a mixture of one volume of alcohol with three of water as the menstruum.

The *dose* is from one-half to one fluidrachm (2–4 cc.).

FLUIDEXTRACTUM TRIFOLII. N. F.

Fluidextract of Trifolium [Fldext. Trifol.]

Prepared by using diluted alcohol as the menstruum. It is without therapeutic virtue.

The *dose* is one fluidrachm (4 cc.).

FLUIDEXTRACTUM TRIFOLII COMPOSITUM. N. F.

Compound Fluidextract of Trifolium [Fldext. Trifol. Co.]

This represents 21.5 per cent. each of trifolium, glycyrrhiza, and berberis with half that quantity of cascara amarga, lappa, phytolacca, stillingia, and 3 per cent. of xanthoxylum. What is to be hoped from such a conglomeration of useless remedies is a conundrum.

The official *dose* is given as one fluidrachm (4 cc.).

FLUIDEXTRACTUM TRILLII. N. F.

Fluidextract of Trillium [Fldext. Trill.]

Prepared by using three volumes of alcohol and one volume of water as the menstruum.

The *dose* is from thirty to sixty minims (2–4 cc.).

FLUIDEXTRACTUM TRITICI. N. F.

Fluidextract of Triticum [Fldext. Tritic.]

This is prepared with an aqueous menstruum to which is added 20 per cent. of alcohol as a preservative.

The *dose* is from two to four fluidrachms (8–15 cc.).

FLUIDEXTRACTUM VALERIANÆ. N. F.

Fluidextract of Valerian [Fldext. Valer.]

Prepared by using four volumes of alcohol and one volume of water as the menstruum.

The *dose* is from thirty to sixty minims (2–4 cc.).

FLUIDEXTRACTUM VERBASCI FOLIORUM. N. F.

Fluidextract of Mullein Leaves [Fldext. Verbasc. Fol.]

Prepared by using diluted alcohol as the menstruum.

The *dose* is from one to two fluidrachms (4–8 cc.).

FLUIDEXTRACTUM VIBURNI OPULI. N. F.

Fluidextract of Viburnum Opulus [Fldext. Viburn. Opul.]

Prepared by using two volumes of alcohol and one volume of water as the menstruum.

The *dose* is from one-half to one fluidrachm (2–4 cc.).

FLUIDEXTRACTUM VIBURNI PRUNIFOLII. N. F.

Fluidextract of Viburnum Prunifolium [Fldext. Viburn. Prun.]

This is made with a mixture of two volumes of alcohol and one of water as the menstruum.

The *dose* is from thirty to sixty minims (2–4 cc.).

FLUIDEXTRACTUM XANTHOXYLI. N. F.

Fluidextract of Xanthoxylum [Fldext. Xanthox.]

This is made with a menstruum of three volumes of alcohol and one of water.

The *dose* is from one-half to one fluidrachm (2–4 cc.).

FLUIDEXTRACTUM ZEÆ. N. F.

Fluidextract of Zea [Fldext. Zea.]

Made with diluted alcohol.

The *dose* is from one to three fluidrachms (4–12 cc.).

FLUIDGLYCERATA. N. F.

Fluidglycerates

Fluidglycerates are intended to be of the same drug strength as fluidextracts. They contain approximately 50 per cent., by volume, of glycerin and no alcohol. Fluidglycerates made from drugs that do not require either an acid or an alkaline menstruum may be prepared by a general process which embodies maceration, percolation, and evaporation to a given volume. The preparation is then allowed to stand for a few days, and the clear portion decanted and the remainder strained.

FLUIDGLYCERATUM CASCARÆ SAGRADÆ. N. F.

Fluidglycerate of Cascara Sagrada [Fldglycer. Casc. Sagr.]

Prepared from cascara sagrada according to the general process.

The *dose* is ten to twenty minims (0.6–1.2 cc.).

FLUIDGLYCERATUM CASCARÆ SAGRADÆ AROMATICUM. N. F.

Aromatic Fluidglycerate of Cascara Sagrada [Fldglycer. Casc. Sagr. Arom.]

Prepared from cascara sagrada by removing its bitter taste with calcium oxide and subsequently flavoring with fluidglycerate of licorice and oils of fennel, clove, and cinnamon.

The *dose* is from fifteen to thirty minims (1–2 cc.).

FLUIDGLYCERATUM GLYCYRRHIZÆ. N. F.

Fluidglycerate of Glycyrrhiza [Fldglycer. Glycyrrh. Fluidglycerate of Licorice]

Prepared from glycyrrhiza (licorice) by the general process. It is used as a flavoring agent.

FLUIDGLYCERATUM KRAMERIÆ. N. F.

Fluidglycerate of Krameria [Fldglycer. Kramer.]

Prepared from krameria by the general process.

The *dose* is from fifteen to thirty minims (1–2 cc.).

FLUIDGLYCERATUM RHEI. N. F.

Fluidglycerate of Rhubarb [Fldglycer. Rhei]

Prepared from rhubarb by the general process.

The *dose* is from fifteen to thirty minims (1–2 cc.).

FORMALDEHYDUM CRESOLATUM. N. F.

Cresolated Formaldehyde [Formal. Cresol.]

This is a mixture of 40 parts of orthocresol (see *Cresol*, Part I) with 60 parts of solution of formaldehyde. It is used as a disinfectant.

GARGARISMA GUAIACI COMPOSITUM. N. F.

Compound Gargle of Guaiac [Garg. Guaiac. Co.]

This gargle contains 10 per cent. each of ammoniated tincture of guaiac and compound tincture of cinchona, 20 per cent. of clarified honey, and 4 per cent. of potassium chlorate, and oil of peppermint enough to flavor. Used as a local stimulant for the throat.

GLYCERITUM BISMUTHI. N. F.

Glycerite of Bismuth [Glycer. Bism.]

"One hundred millilitres of glycerite of bismuth yields not less than 12.5 Gm. of bismuth oxide and not more than 13.5 of bismuth oxide (Bi_2O_3) corresponding to about 40 Gm. of Bismuth and Sodium Tartrate." *N. F.* It is made from bismuth subnitrate, nitric acid, tartaric acid, sodium bicarbonate, glycerin, and distilled water. It is used in making other preparations containing bismuth. An assay is provided in the text. As the bismuth in this compound is in a soluble form it does not represent the virtues of bismuth subnitrate which are largely due to the insolubility of that salt.

GLYCERITUM PEPSINI. N. F.

Glycerite of Pepsin [Glycer. Pepsin.]

Five grains of pepsin are represented by 1 fluidrachm of the finished glycerite. The menstruum is acidulated water and glycerin.

The *dose* is forty-five minims (3 cc.).

GLYCERITUM PICIS PINI. N. F.

Glycerite of Tar [Glycer. Pic. Liq.]

Glyceritum Picis Liquidæ, *N. F. IV.*

This glycerite is made from tar, magnesium carbonate, glycerin, alcohol and water. The medicinal virtues of about 4 grains of tar are represented in 1 fluidrachm of the finished glycerite.

The *dose* is one fluidrachm (4 cc.).

GLYCERITUM TRAGACANTHÆ. N. F.

Glycerite of Tragacanth [Glycer. Trag.]

This glycerite contains about 12.5 per cent. of tragacanth with glycerin and water. It is prepared in the form of a thick homogeneous paste. It is used as an excipient for pills.

GLYCERITUM VITELLI. N. F.

Glycerite of Egg Yolk [Glycer. Vitell. Glyconin]

This is a mixture of egg yolk, 45 per cent., and glycerin, 55 per cent. Used as a emulsifying agent.

GLYCEROGELATINA. N. F.

Glycerogelatins

Glycerogelatins originated with Doctor Unna and are soft masses which melt at the temperature of the body. They contain gelatin, glycerin, water and the medicament, and are used in *skin diseases.*

GLYCEROGELATINUM ACIDI SALICYLICI. N. F.

Salicylic Acid Glycerogelatin [Glycerogel. Acid. Salicyl.]

This preparation contains 35 per cent. of glycerin and 10 per cent. of salicylic acid in glycerinated gelatin vehicle. Used as an antiseptic and keratoplastic.

GLYCEROGELATINUM IODOFORMI. N. F.

Iodoform Glycerogelatin [Glycerogel. Iodof.]

This preparation contains 15 per cent. of glycerin, and 10 per cent. of iodoform in glycerinated gelatin vehicle.

GLYCEROGELATINUM ZINCI DURUM. N. F.

Firm Zinc Glycerogelatin [Glycerogel. Zinc. Dur.]

This preparation contains 25 per cent. of glycerin, and 10 per cent. of zinc oxide in 30 per cent. glycerinated gelatin vehicle. Used as a local sedative and protective.

GLYCEROGELATINUM ZINCI MOLLE. N. F.

Soft Zinc Glycerogelatin [Glycerogel. Zinc. Mol.]

This preparation contains 35 per cent. of glycerin and 10 per cent. of zinc oxide in 20 per cent. of glycerinated gelatin vehicle. Used as an astringent and protective.

GOSSYPIUM STYPTICUM. N. F.

Styptic Cotton [Gossyp. Stypt.]

It is made by impregnating purified cotton with diluted solution of ferric chloride, glycerin and water. It should be kept in well closed containers. It is used as a local styptic.

INFUSUM BRAYERÆ. N. F.

Infusum of Brayera [Inf. Brayer.]

This infusion, which must be freshly prepared, is made with 6 per cent. of the drug in boiling water.

The *dose* is eight fluidounces (250 cc.).

INFUSUM GENTIANÆ COMPOSITUM. N. F.

Compound Infusion of Gentian [Inf. Gent. Co.]

This elixir contains 3 per cent. of gentian, flavored with coriander, and bitter orange peel. It is used as a tonic, and is made by percolation.

The *dose* is from one to four fluidrachms (4–15 cc.).

INFUSUM ROSÆ COMPOSITUM. N. F.

Compound Infusion of Rose [Inf. Ros. Co.]

This preparation which deserves a larger use on account of its pleasant flavor and beautiful color is made from red rose, diluted sulphuric acid, sugar and water. It is used as a vehicle or mild astringent.

The *dose* is three fluidounces (100 cc.).

INFUSUM SENNÆ COMPOSITUM. N. F.

Compound Infusion of Senna [Inf. Senn. Co.]

This is the same as the former preparation of the U. S. IX. It represents 6 per cent. of senna and 12 per cent. each of manna and magnesium sulphate.

The *dose* is four fluidounces (120 cc.).

INUNCTUM MENTHOLIS. N. F.

Menthol Inunction [Inunct. Menthol.]

The necessity for the peculiar name of this ointment is not apparent. It is simply a 5 per cent. ointment of menthol in hydrous wool-fat.

INUNCTUM MENTHOLIS COMPOSITUM. N. F.

Compound Menthol Inunction [Inunct. Menthol. Co.]

This preparation contains 5 per cent. of menthol and 10 per cent. of methyl salicylate in hydrous wool fat. It is counter-irritant as well as locally anesthetic.

LAC FERMENTATUM. N. F.

Fermented Milk [Lac. Ferment. Kumyss]

This well known dietetic preparation is made from fresh cow's milk, compressed yeast, and sugar, properly fermented, and is used as a food for invalids.

The *dose* is eight fluidounces (250 cc.).

LAVATIO ORI. N. F.

Mouth Wash [Lavat. Ori]

This is a sweetened aromatic solution of soap colored with fuchsin. Its therapeutic virtues are not very obvious.

LINIMENTUM ACONITI ET CHLOROFORMI. N. F.

Liniment of Aconite and Chloroform [Lin. Aconit. et Chlorof.]

This preparation contains 4.5 per cent. fluidextract of aconite and 12.5 per cent. of chloroform in a mixture of alcohol and soap liniment. It must not be confused with the dental liniment of aconite.

LINIMENTUM AMMONIÆ. N. F.

Ammonia Liniment [Lin. Ammon.]

Hartshorn Liniment; Volatile Liniment.

This is the same as the former preparation of the U. S. IX. It is used externally as a rubefacient.

LINIMENTUM BELLADONNÆ. N. F.

Belladonna Liniment [Lin. Bellad.]

This is, like the former preparation of the U. S. IX, a 5 per cent. solution of camphor in fluidextract of belladonna.

LINIMENTUM CALAMINÆ. N. F.

Calamine Liniment [Lin. Calam.]

This contains 8 per cent. each of prepared calamine and zinc oxide suspended in lime liniment.

LINIMENTUM OPII COMPOSITUM. N. F.

Compound Liniment of Opium [Lin. Opii Co.]

Canada Liniment.

This liniment contains 10 per cent. of tincture of opium, 22 per cent. of oil of turpentine and 35 per cent. of ammonia water, with camphor, alcohol and oil of peppermint, made into a somewhat permanent emulsion with fresh egg albumen. It is used as a stimulating anodyne application.

LINIMENTUM SAPONATO-CAMPHORATUM. N. F.

Camphorated Soap Liniment [Lin. Sapon.-Camph.]

Solid Opodeldoc.

This liniment contains freshly prepared sodium stearate made by combining monohydrated sodium carbonate and stearic acid, perfumed with camphor, oils of thyme and rosemary and ammonia water. It is a useless survival of a former fad.

LINIMENTUM SAPONIS MOLLIS COMPOSITUM. N. F.

Compound Liniment of Soft Soap [Lin. Sapon. Mol. Co.]

Tinctura Saponis Viridis Composita.

There is no change in this preparation which was formerly classed as compound tincture of green soap. It contains soft soap, oil of cade, and alcohol.

LINIMENTUM SINAPIS COMPOSITUM. N. F.

Compound Liniment of Mustard [Lin. Sinap. Co.]

This preparation contains 3 per cent. of volatile oil of mustard, with fluidextract of mezereum, camphor, castor oil, and alcohol. It is an active rubefacient.

LINIMENTUM TEREBINTHINÆ. N. F.

Turpentine Liniment [Lin. Terebinth.]

Kentish Ointment.

This differs materially from the *Linimentum Terebinthinæ* of the Br. (see Part I). It is used as a stimulating application to burns and ulcers.

LINIMENTUM TEREBINTHINÆ ACETICUM. N. F.

Acetic Turpentine Liniment [Lin. Terebinth. Acet.]

Linimentum Album; Stokes' Liniment; St. John Long's Liniment.

This liniment contains 40 per cent. of oil of turpentine, fresh egg, oil of lemon, acetic acid and rose water. It is a powerful counter-irritant.

LIQUOR ALUMINI ACETATIS. N. F.

Solution of Aluminum Acetate [Liq. Alum. Acet.]

Liquor Burowii; Burow's Solution.

"An aqueous solution containing not less than 4.5 and not more than 5.5 Gm. of neutral aluminum acetate [$Al(C_2H_3O_2)_3 = 204.10$] in each 100 cc." *N. F.* It is made by the reactions between lead acetate and aluminum sulphate in aqueous solution. A process of assay is also given in the text. It should be noted that this differs from the solution of aluminum acetate of the N. F. III which is now known as the solution of the subacetate. It is astringent and antiseptic.

LIQUOR ALUMINI SUBACETATIS. N. F.

Solution of Aluminum Subacetate [Liq. Alum. Subacet.]

"An aqueous solution containing not less than 7.5 Gm. and not more than 8 Gm. of basic aluminum acetate [$Al(C_2H_3O_2)_2OH = 162.08$] in each 100 cc." *N. F.* It is made from aluminum sulphate, acetic acid, precipitated calcium carbonate and water. An assay process is also given in the text. This preparation corresponds closely to the *Liquor Alumini Acetici* of the German Pharmacopœia. It is an active germicide, as well as astringent, and is used both as a gargle and as a surgical dressing. It should generally be diluted with from 4 to 8 parts of water.

LIQUOR ANTISEPTICUS. N. F.

Antiseptic Solution [Liq. Antisept.]

This is a hydro-alcoholic solution containing 2.5 per cent. of boric acid with traces of thymol, eucalyptol, menthol and methyl salicylate. While it possesses feeble antiseptic properties, it is chiefly useful to flavor mouth-washes.

LIQUOR AROMATICUS ALKALINUS. N. F.

Alkaline Aromatic Solution [Liq. Aromat. Alk.]

Liquor Antisepticus Alkalinus, *N. F. IV.*

This solution contains 2 per cent. each of sodium borate and potassium bicarbonate with small amounts of thymol, eucalyptol and methyl salicylate and is sweetened with glycerin and colored with cudbear.

LIQUOR AURI ET ARSENI BROMIDI. N. F.

Solution of Gold and Arsenic Bromide [Liq. Aur. et Arsen. Brom.]

This is a reddish-brown solution resulting from the interaction between arsenic trioxide, bromauric acid and bromine. It was at one time lauded as a remedy for diabetes but probably owes any value it may possess chiefly to the arsenic in it.

The *dose* is from two to five minims (0.12–0.3 cc.).

LIQUOR BISMUTHI. N. F.

Solution of Bismuth [Liq. Bism.]

This solution is made from glycerite of bismuth, alcohol, and distilled water. About 3 grains of bismuth and sodium tartrate are represented in 1 fluidrachm of the finished solution. It is used as an intestinal astringent, but does not possess the therapeutic virtues of the insoluble bismuth salts.

The *dose* is one fluidrachm (4 cc.).

LIQUOR CALCIS SULPHURATÆ. N. F.

Solution of Sulphurated Lime [Liq. Calc. Sulphurat.]

Solution of Oxysulphuret of Calcium; Vleminckx' solution; Vleminckx' Lotion.

This solution is made by boiling together lime, sublimed sulphur and water. It is used as an external application in skin diseases.

LIQUOR CARMINI. N. F.

Solution of Carmine [Liq. Carmin.]

This solution is made from carmine, ammonia water, glycerin and water. It is used as a red coloring solution.

LIQUOR CHLORI COMPOSITUS. N. F.

Compound Solution of Chlorine [Liq. Chlor. Co.]

Chlorine Water.

This is "an aqueous solution containing, when freshly made, a mixture of chlorine and chlorine oxides equivalent to about 0.35 Gm. of available chlorine in each one hundred cc." *N. F.* It is made by reacting upon potassium chlorate with hydrochloric acid and then dissolving the products of the reaction in cold distilled water; this is practically identical with the U. S. P. VIII process. It is used as an intestinal antiseptic.

The *dose* is one fluidrachm (4 cc.).

LIQUOR COCCI. N. F.

Liquor Coccineus, N. F. III

Cochineal Color [Liq. Cocci]

This solution is made from cochineal, potassium carbonate, alum, potassium bitartrate, alcohol, glycerin, and water. Like the solution of carmine, it is used to color preparations red.

LIQUOR FERRI ALBUMINATI. N. F.

Solution of Albuminized Iron [Liq. Ferr. Albumin.]

Solution of Albuminate of Iron; Solution of Ferric Albuminate.

The formula for this preparation has been materially altered. It is now made by dissolving albuminized iron (see *Ferri Albuminatum*, Part I) in an aromatic vehicle. It is a clear yellowish-brown liquid, containing 5 per cent. of albuminized iron, or about $^2/_5$ of a grain of metallic iron in the form of albuminate, in 1 fluidrachm of the finished solution.

The *dose* is from two to four fluidrachms (8–15 cc.).

LIQUOR FERRI CITRATIS. N. F.

Solution of Ferric Citrate [Liq. Ferr. Cit.]

This is "an aqueous solution containing ferric citrate corresponding to not less than 8.75 Gm. of metallic iron (Fe) in each 100 cc." *N. F.* It is a dark reddish-brown liquid with an acid reaction. It is made from solution of ferric sulphate, citric acid, ammonia water, and water. A process of assay is given in the text.

The *dose* is ten minims (0.6 cc.).

LIQUOR FERRI PEPTONATI. N. F.

Solution of Peptonized Iron [Liq. Ferr. Pepton.]

It is made from pepsin, fresh egg albumen, hydrochloric acid, solution of ferric oxychloride, alcohol, and sodium citrate made up into a pleasantly flavored preparation with oil of orange, acetic ether, and vanillin, using glycerin, syrup and distilled water. It contains 1.75 per cent. of peptonized iron—equivalent to about $^2/_5$ of a grain of metallic iron—in 1 fluidrachm of the finished solution.

The *dose* is from two to four fluidrachms (8–15 cc.).

LIQUOR FERRI PEPTONATI ET MANGANI. N. F.

Solution of Peptonized Iron and Manganese [Liq. Ferr. Pepton. et Mangan.]

Solution of Iron Peptonate and Manganese.

This preparation is made from the same ingredients and in a similar manner to the foregoing preparation with the addition of soluble manganese citrate.

The *dose* is two fluidrachms (8 cc.).

LIQUOR FERRI SALICYLATIS. N. F.

Solution of Ferric Salicylate [Liq. Ferr. Salicyl. Salicylated Mixture of Iron]

This preparation contains sodium salicylate, tincture of ferric citro-chloride, ammonium carbonate, citric acid, methyl salicylate, glycerin, and distilled water. Each fluidrachm is equivalent to about 7½ grains of sodium salicylate and 7½ minims of tincture of ferric citro-chloride. It has been recommended for cases of chronic rheumatism complicated with anemia.

The *dose* is from one to two fluidrachms (4–8 cc.).

LIQUOR FERRI SUBSULPHATIS. N. F.

Solution of Ferric Subsulphate [Liq. Ferr. Subsulph.]

Monsel's Solution; Solution of Basic Ferric Sulphate.

This is "an aqueous solution containing basic ferric sulphate corresponding to not less than 20 Gm. and not more than 22 Gm. of Fe in each 100 cc." It is essentially similar to the preparation formerly recognized by the U. S. IX, although the proportion of ingredients used in its manufacture is somewhat different. The ferrous sulphate is partially oxidized to the ferric condition by boiling with nitric acid, but the amount of sulphuric acid being insufficient to form a normal sulphate, the resulting salt has the approximate composition, $5Fe_2(SO_4)_3.Fe_2(OH)_6$. It forms a reddish-brown acid liquid. It is a valuable astringent and styptic.

The *dose* is from one to three minims (0.06–0.20 cc.).

LIQUOR HYDRASTINÆ COMPOSITUS. N. F.

Compound Solution of Hydrastine [Liq. Hydrastin. Co.]

Colorless Hydrastine Solution.

This preparation contains 0.3 per cent. each of the chlorides of hydrastine, aluminum, calcium, and magnesium with 0.1 per cent. of potassium chloride in solution in glycerin and water. It owes its activity chiefly to the hydrastine.

The *dose* is from one to two fluidrachms (4–8 cc.).

LIQUOR HYPOPHOSPHITUM COMPOSITUS. N. F.

Compound Solution of Hypophosphites [Liq. Hypophos. Co.]

This solution represents in each fluidrachm ⅛ grain quinine, 1–250th of a grain of strychnine and ¼ grain of iron, with calcium, potassium, sodium, and manganese hypophosphites.

The *dose* is one to four fluidrachms (4–15 cc.).

LIQUOR IODI ET ZINCI PHENOLSULPHONATIS. N. F.

Solution of Iodine and Zinc Phenolsulphonate. [Liq. Iodi et Phenolsul.]

Pyorrhea Astringent.

This contains 15 Gm. each of zinc phenolsulphonate and potassium iodide with 20 Gm. of iodine in 100 cc. "This solution should be recently prepared when dispensed." *N. F.* It is used locally.

LIQUOR IODI PHENOLATUS. N. F. Liquor Iodi Carbolatus, N. F. III

Phenolated Solution of Iodine [Liq. Iod. Phenol.]

Carbolized Solution of Iodine; Boulton's Solution; French Mixture.

This solution is made from compound solution of iodine, liquefied phenol, glycerin, and water. The direction to expose it to sunlight until it is decolorized destroys much of its therapeutic value. It represents about 0.5 per cent. of phenol. It is used externally.

LIQUOR PANCREATINI. N. F.

Solution of Pancreatin [Liq. Pancreat.]

Liquor Pancreaticus; Pancreatic Solution.

This solution is made from pancreatin, sodium bicarbonate, glycerin, compound spirit of cardamom, alcohol, purified talc and water. About 1 grain of pancreatin is represented in 1 fluidrachm of the finished solution. It is used as a digestive.

The *dose* is one to four fluidrachms (4–15 cc.).

LIQUOR PEPSINI. N. F.

Solution of Pepsin [Liq. Pepsin.]

This solution contains glycerite of pepsin, hydrochloric acid, glycerin and water. "One cc. of this solution will digest 10 Gm. of egg albumen, carrying out the test according to the details of the U. S. P. X assay under *Pepsinum.*" *N. F.* It is too weak to be of therapeutic value.

The *dose* is from two to four fluidrachms (8–15 cc.).

LIQUOR PEPSINI ANTISEPTICUS. N. F.

Antiseptic Solution of Pepsin [Liq. Pepsin. Antisept.]

This solution represents 5 per cent. of pepsin with traces of menthol, eucalyptol and methyl salicylate. It is much stronger than the preceding; "One-tenth cc. of this solution will digest 10 Gm. of egg albumen when carrying out the test according to the details of the U. S. P. X assay under *Pepsinum.*" *N. F.* It is used externally in the treatment of old sores to assist their healing.

LIQUOR PEPSINI AROMATICUS. N. F.

Aromatic Solution of Pepsin [Liq. Pepsin. Arom.]

This solution of pepsin is flavored with cinnamon, pimenta and clove. About 1 grain of pepsin is represented in 1 fluidrachm of finished solution. It is used as a digestive. "One-fourth cc. of the solution digests 10 Gm. of egg albumen, carrying out the test according to the details of the U. S. P. under *Pepsinum.*" *N. F.*

The *dose* is from two to four fluidrachms (8–15 cc.).

LIQUOR PHOSPHATUM ACIDUS. N. F.

Acid Solution of Phosphates [Liq. Phos. Acid. Solution of Acid Phosphates]

This is now made by dissolving calcium and magnesium carbonate in phosphoric acid and water. It represents 7¼ grains of dibasic calcium phosphate in each fluidrachm.

The *dose* is one fluidrachm (4 cc.).

LIQUOR PHOSPHATUM COMPOSITUS. N. F.

Compound Solution of Phosphates [Liq. Phos. Co.]

This is a polypharmacal preparation containing the phosphates of ammonium, calcium, iron, potassium, and sodium held in aqueous solution by the use of glycerin and citric acid. It is used for making the compound syrup of phosphates.

LIQUOR PHOSPHORI. N. F.

Solution of Phosphorus [Liq. Phosphor.]

Thompson's Solution of Phosphorus.

This solution is made from phosphorus, dehydrated alcohol, spirit of peppermint and glycerin. It represents 0.07 per cent. of phosphorus. It is used as a tonic and stimulant in nervous diseases.

The *dose* is from ten to fifteen minims (0.6–1.0 cc.).

LIQUOR PICIS CARBONIS. N. F.

Coal Tar Solution [Liq. Pic. Carbon.]

Liquor Carbonis Detergens.

This preparation, sometimes known by the name of *Liquor Carbonis Detergens,* is made by digesting 200 Gm. of coal tar and 100 Gm. of soap bark with enough alcohol to make 1000 cc. It is used externally in skin diseases.

LIQUOR PLUMBI SUBACETATIS DILUTUS. N. F.

Diluted Solution of Lead Subacetate. [Liq. Plumb. Subacet. Dil.]

Lead Water.

This is a mixture of 35 parts of solution of lead subacetate with 965 parts of water. It is too weak to be of any real value. It is used locally.

LIQUOR POTASSII IODIDI. N. F.

Solution of Potassium Iodide [Liq. Pot. Iod.]

Saturated Solution of Potassium Iodide.

"An aqueous solution containing not less than 97 Gm. and not more than 103 Gm. of KI (166.02) in each 100 cc." *N. F.*

The *dose* is from five to ten minims (0.3–0.6 cc.) or more.

LIQUOR PROCAINÆ HYDROCHLORIDI.

Solution of Procaine Hydrochloride [Liq. Procain. Hydroch.]

Dental Anesthetic Solution.

This solution contains 2 Gm. of procaine hydrochloride in each 100 cc. of 0.9 per cent. sodium chloride solution, a little thymol being present as a preservative. The N. F. has a note that "to each cc. of this solution add 9.95 cc. of solution of Epinephrine Hydrochloride just before employing hypodermically" but such a memorandum seems to us an infringement on the prerogatives of the physician.

LIQUOR SODÆ ET MENTHÆ. N. F.

Solution of Soda and Mint [Liq. Sod. et Menth.]

Mistura Sodæ et Menthæ; Soda Mint.

This preparation contains sodium bicarbonate, aromatic spirit of ammonia and spearmint or peppermint water. Each fluidrachm contains 3 grains of the bicarbonate and 0.6 minim of aromatic spirit of ammonia. It is used as an antacid and carminative.

The *dose* is from two to four fluidrachms (8–15 cc.).

LIQUOR SODII ARSENATIS. N. F.

Solution of Sodium Arsenate [Liq. Sod. Arsenat.]

" An aqueous solution containing not less than 0.975 Gm. and not more than 1.025 Gm. of Na_2HAsO_4 (185.97) in each 100 cc." *N. F.* This is the same as the solution formerly official in the U. S. IX.

The *dose* is from three to eight minims (0.2–0.5 cc.).

LIQUOR SODII ARSENATIS, PEARSONII. N. F.

Pearson's Solution of Sodium Arsenate [Liq. Sod. Arsen. Pearson.]

Liquor Arsenicalis Pearsonii.

This preparation should not be confounded with the preceding Liquor Sodii Arsenatis, which is ten times stronger than Pearson's solution. It contains about ⅙ per cent. of crystallized sodium arsenate, or about ⅒ per cent. of anhydrous sodium arsenate. Whenever it is prescribed or dispensed, the name " Pearson " should be specified, to avoid serious mistakes.

The *dose* is from twenty to thirty minims (1–2 cc.).

LIQUOR SODII BORATIS COMPOSITUS. N. F.

Compound Solution of Sodium Borate [Liq. Sod. Bor. Co.]

Dobell's Solution.

This solution contains about 1.5 per cent. each of sodium borate and sodium bicarbonate and 0.3 per cent. of phenol, with glycerin and water. It is widely used as a cleansing wash in inflammations of the nose and pharynx.

LIQUOR SODII CITRATIS. N. F.

Solution of Sodium Citrate [Liq. Sod. Cit.]

Mistura Sodii Citratis; Potio Rivierii.

This solution is made with 2 per cent. of citric acid and 2.5 per cent. of sodium bicarbonate in distilled water. It should be freshly prepared. The amount of sodium citrate formed, about 1.5 grains for each fluidrachm, is so small that the solution has scarcely any effect beyond that of a mildly saline drink.

The *dose* is officially given as two fluidrachms (8 cc.) but it would require upwards of an ounce to exercise any therapeutic effect.

LIQUOR SODII PHOSPHATIS COMPOSITUS. N. F.

Compound Solution of Sodium Phosphate [Liq. Sod. Phos. Co.]

This preparation contains sodium phosphate crystals, citric acid, glycerin, and distilled water. Each cc. represents 1 gramme of crystallized sodium phosphate. It is used as a laxative.

The *dose* is from one to two fluidrachms (4–8 cc.).

LOTIO ALBA VETERINARIA. N. F.

Veterinary White Lotion [Lot. Alb. Vet.]

This preparation is the result of the reaction between zinc sulphate (23 Gm.) and lead acetate (30 Gm.) in 1000 cc. of water.

LOTIO AMMONIACALIS CAMPHORATA. N. F. Aqua Sedativa, N. F. III

Ammoniated Camphor Wash [Lot. Ammon. Camph.]

Aqua Sedativa; Sedative Water; Eau Sedative de Raspail.

This is an aqueous solution containing 6 per cent. each of sodium chloride and ammonia water, with 10 per cent. spirit of camphor.

LOTIO CALAMINÆ. N. F.

Calamine Lotion [Lot. Calam.]

This preparation contains 8 Gm. each of prepared calamine and zinc oxide in 100 cc. of lime water with a little glycerin.

LOTIO CALAMINÆ COMPOSITUM. N. F.

Compound Calamine Lotion [Lot. Calam. Co.]

This is a 10 per cent. solution of liquefied phenol in calamine lotion.

LOTIO FLAVA. N. F.

Yellow Lotion [Lot. Flav.]

Yellow Wash; Aqua Phagedænica Flava.

It is made with 0.3 per cent. of corrosive mercuric chloride in lime water slightly diluted with water. The mercury is present as a yellow hydroxide in the finished preparation. It is used externally in skin diseases. It is slightly weaker than the corresponding preparation of the Br. (See *Lotio Hydrargyri Flava,* Part I.)

LOTIO NIGRA. N. F.

Black Lotion [Lot. Nigr.]

Black Wash; Aqua Phagedænica Nigra.

It is made with 0.875 per cent. (formerly 0.75 per cent.) of mild mercurous chloride in lime water slightly diluted with water. The mercury is largely present as a black suboxide. It is used externally in skin diseases. It exceeds in strength the similar Br. preparation (see *Lotio Hydrargyri Nigra,* Part I).

LOTIO PLUMBI ET OPII. N. F.

Lotion of Lead and Opium [Lot. Plumb. et Opii.]

Lead and Opium Wash.

It contains, in each 100 cc., 1.75 grammes of lead acetate and 3.5 grammes of tincture of opium. It is used as an astringent and sedative external application.

MAGMA BISMUTHI. N. F.

Bismuth Magma [Magma Bism.]

Milk of Bismuth.

This is practically the same as the preparation formerly recognized by the U. S. IX. It contains "not less than 5.6 Gm. of Bi_2O_3 in each 100 cc., corresponding to not less than 7 Gm. of bismuth subnitrate in each 100 cc." *N. F.*

The *dose* is from one to two fluidrachms (4–8 cc.).

MASSA COPAIBÆ. N. F.

Mass of Copaiba [Mass. Copaib.]

Solidified Copaiba.

This is a combination of copaiba with a hydrated magnesium oxide reduced to a pilular consistence. It represents about 94 per cent. of copaiba.

The *dose* is from fifteen to thirty grains (1–2 Gm.).

MEL ROSÆ ET SODII BORATIS. N. F.

Honey of Rose and Sodium Borate [Mel. Ros. et Sod. Bor.]

Honey of Rose with Borax.

This preparation is made with borax, glycerin, and honey of rose. It is used as an astringent application.

MEL SODII BORATIS. N. F.

Honey of Sodium Borate [Mel. Sod. Bor.]

Mel Boracis; Honey and Borax.

This preparation is made with borax, glycerin, and clarified honey. It is used as a local application in sore throat.

MENTHOL CAMPHORATUM. N. F. Campho-Menthol, N. F. III

Camphorated Menthol [Menthol. Camph.]

Camphor and Menthol.

Equal parts by weight of camphor and menthol with a small proportion of alcohol added. Applied locally in *neuralgia*.

MISTURA ADSTRINGENS. N. F. Mistura Adstringens et Escharotica, N. F. III

Astringent Mixture [Mist. Adstring.]

Villate's Mixture.

This preparation is made from solution of lead subacetate, copper sulphate, zinc sulphate and diluted acetic acid. It should be well shaken before dispensing to insure the even distribution of the precipitated lead sulphate. It is used externally as an astringent and escharotic.

MISTURA CARMINATIVA. N. F.

Carminative Mixture [Mist. Carminat.]

Dalby's Carminative.

It is made from magnesium carbonate, potassium carbonate, tincture of opium, oils of caraway, fennel, and peppermint, with syrup and water. It contains 1–40th of a grain of opium in 10 minims of the finished mixture.

The *dose* for an infant is from five to ten minims (0.3–0.6 cc.).

MISTURA CHLORALIS ET POTASSII BROMIDI COMPOSITA. N. F.

Compound Mixture of Chloral and Potassium Bromide [Mist. Chloral. et Pot. Brom. Co.]

Chloral and Bromide Compound.

This preparation represents about 12 grains each of hydrated chloral and potassium bromide, and ⅛ grain each of the extracts of cannabis and hyoscyamus in each fluidrachm of the finished mixture.

The *dose* is one fluidrachm (4 cc.).

MISTURA CHLOROFORMI ET MORPHINÆ COMPOSITA. N. F.

Compound Mixture of Chloroform and Morphine [Mist. Chlorof. et Morph. Co.]

Mistura Chloroformi et Cannabis Indicæ Composita, *N. F. III;* Chloroform Anodyne.

This preparation contains chloroform, ether, tincture of cannabis, tincture of capsicum, morphine sulphate, oil of peppermint, glycerin, water, and alcohol. About 7½ minims of chloroform, 11 minims of tincture of cannabis, 1½ minims of tincture of capsicum, 1–7th of a grain of morphine sulphate, are represented in 1 fluidrachm of the finished mixture. It should not be confounded with chlorodyne (see *Tinctura Chloroformi et Morphinæ Composita*, Part I), which is a much stronger preparation.

The *dose* is from thirty to sixty minims (2–4 cc.).

MISTURA COPAIBÆ. N. F.

Copaiba Mixture [Mist. Copaib.]

Lafayette Mixture.

This preparation contains copaiba, spirit of nitrous ether, compound tincture of lavender, solution of potassium hydroxide, syrup, and mucilage of acacia. There is 7½ minims each of copaiba and sweet spirit of niter in one fluidrachm.

The *dose* is from two to four fluidrachms (8–15 cc.).

MISTURA COPAIBÆ ET OPII. N. F.

Mixture of Copaiba and Opium [Mist. Copaib. et Opii.]

Chapman's Mixture.

This preparation contains double the proportions of copaiba and spirit of nitrous ether in the above, and in addition two minims of tincture of opium in each fluidrachm. It is used in *gonorrhea*.

The *dose* is from one to two fluidrachms (4–8 cc.).

MISTURA MAGNESIÆ, ASAFŒTIDÆ ET OPII. N. F. Mistura Magnesiæ et Asafœtidæ, N. F. III

Mixture of Magnesia, Asafetida and Opium [Mist. Mag., Asafœt. et Opii.]

Dewee's Carminative.

This preparation contains 5 per cent. magnesium carbonate, 7.5 per cent. tincture of asafetida, 1 per cent. tincture of opium, with sugar and water. It is used as an anodyne and carminative.

The *dose* is from two to four fluidrachms (8–15 cc.).

MISTURA OLEO-BALSAMICA. N. F.

Oleo-Balsamic Mixture [Mist. Ol.-Balsam.]

Hoffmann's Balsam.

This preparation contains 0.4 per cent. each of the oils of lavender, thyme, lemon, nutmeg, and cinnamon, with eugenol, balsam of Peru, and alcohol. Its greatest value lies in its pleasant odor.

MISTURA OPII ET CHLOROFORMI COMPOSITA. N. F.

Compound Mixture of Opium and Chloroform [Mist. Opii et Chlorof. Co.]

Squibb's Diarrhea Mixture.

This preparation contains 20 per cent. each of tincture of opium and spirit of camphor, with tincture of capsicum, chloroform and alcohol.

The *dose* is from thirty to forty minims (2–2.6 cc.).

MISTURA OPII ET RHEI COMPOSITA.

Compound Mixture of Opium and Rhubarb [Mist. Opii et Rhei Co.]

Sun Cholera Mixture.

This preparation contains 10 per cent. each of tincture of capsicum and tincture of rhubarb, and 20 per cent. each of tincture of opium, spirit of camphor, and spirit of peppermint, dissolved in alcohol.

The *dose* is from twenty to forty minims (1.3–2.5 cc.).

MISTURA PECTORALIS, STOKES. N. F.

Stokes' Expectorant [Mist. Pect. Stokes]

Each fluidrachm of this preparation represents, approximately, 1 grain of ammonium carbonate, 2 minims each of fluidextracts of squill and senega, and 10 minims of paregoric dissolved in water and syrup of tolu. It is used as an expectorant.

The *dose* is one fluidrachm (4 cc.).

MISTURA RHEI ALKALINA. N. F. Syrupus Rhei et Potassii Compositus, N. F. III

Alkaline Mixture of Rhubarb [Mist. Rhei Alk.]

Elixir Rhei Alkalinum; Neutralizing Cordial.

This preparation contains in each fluidrachm 1 minim of fluidextract of rhubarb, ½ minim of fluidextract of hydrastis and 1 grain of potassium carbonate.

The official *dose* is given as one fluidrachm (4 cc.) but this is evidently intended for infants; the adult dose would be one or two fluidounces (15–30 cc.).

MISTURA RHEI COMPOSITA. N. F. Mistura Rhei et Sodæ, U. S. P. VIII

Compound Mixture of Rhubarb [Mist. Rhei Co.]

Mixture of Rhubarb and Soda.

Each fluidrachm of this contains approximately 1 minim of fluidextract of rhubarb, ⅙ minim of fluidextract of ipecac and 2 grains of sodium bicarbonate and 2 minims of spirit of peppermint.

The *dose* given by the N. F. is one fluidrachm (4 cc.) which is obviously intended for infants.

MUCILAGO CHONDRI. N. F.

Mucilage of Chondrus [Mucil. Chondr.]

Mucilage of Irish Moss.

This preparation contains 3 per cent. of Irish moss in water. It is used as an emulsifying agent and demulcent.

MUCILAGO SASSAFRAS MEDULLÆ. N. F.

Mucilage of Sassafras Pith [Mucil. Sassaf. Medul.]

This preparation contains 3 grammes of sassafras pith in each 100 cc. It is a bland mucilage used principally in eye lotions and should always be freshly prepared.

The *dose* is four fluidrachms (15 cc.).

MULLÆ. N. F.

Mulls

Steatins; Salve Mulls.

The mulls or salve mulls are very stiff ointments spread upon soft muslin (mull) similar to a plaster. The base is usually suet or lard, but wax or even lead plaster are used in some of the members of the group. They are usually made in a wholesale manner, by machinery, but the N. F. gives formulas for the retail preparation of several.

MULLA ACIDI SALICYLICI. N. F.

Salicylic Acid Mull [Mull. Ac. Salicyl.]

Unguentum Salicylatum Extensum.

This preparation contains 10 per cent. of salicylic acid with a mixture of benzoinated suet and benzoinated lard.

MULLA CREOSOTI SALICYLATA. N. F.

Salicylated Creosote Mull [Mull. Creosot. Salicyl.]

Unguentum Creosoti Salicylatum Extensum.

This preparation contains 10 per cent. of salicylic acid and 20 per cent. of creosote in a mixture of benzoinated suet and yellow wax.

MULLA HYDRARGYRI CHLORIDI CORROSIVI. N. F.

Corrosive Mercuric Chloride Mull [Mull. Hydrarg. Chlor. Corros.]

Unguentum Hydrargyri Chloridi Corrosivi Extensum.

This preparation contains 0.2 per cent. of corrosive sublimate in a mixture of benzoinated suet, benzoinated lard, and alcohol.

MULLA ZINCI. N. F.

Zinc Mull [Mull. Zinc.]

Unguentum Zinci Extensum.

This preparation is made with zinc oxide, 10 per cent., in a mixture of benzoinated suet and benzoinated lard.

NEBULA AROMATICA. N. F.

Aromatic Oil Spray [Nebul. Arom.]

Aromatol.

This preparation contains phenol, menthol, thymol, camphor, benzoic acid, eucalyptol, oil of cinnamon, oil of clove and methyl salicylate in small proportions, in solution in light liquid petrolatum. It is used in the form of a nebula, or spray.

NEBULA EUCALYPTOLIS. N. F.

Eucalyptol Spray [Nebul. Eucalyptol.]

This preparation contains 5 per cent. of eucalyptol in solution in light liquid petrolatum.

NEBULA MENTHOLIS. N. F.

Menthol Spray [Nebul. Menthol.]

This preparation consists of a solution of 2 per cent. of menthol in light liquid petrolatum.

NEBULA MENTHOLIS COMPOSITA. N. F.

Compound Menthol Spray [Nebul. Menthol. Co.]

This preparation contains 1 per cent. each of menthol and camphor, with smaller amounts of methyl salicylate, eucalyptol, and oil of cinnamon in solution in light liquid petrolatum.

NEBULA THYMOLIS. N. F.

Thymol Spray [Nebul. Thymol.]

This preparation contains 1 per cent. of thymol in solution in light liquid petrolatum.

ODONTALGICUM. N. F.

Toothache Remedy [Odontalg.]

This weirdly named mixture preparation is a mixture of 1 part of oil of cinnamon, 2 parts of phenol and 3 parts of methyl salicylate. It is intended for local application to carious teeth.

OLEA INFUSA. N. F.

Infused Oils [Ol. Inf.]

The formula for these is a general one. They are made by moistening the air dried drug with alcohol and ammonia water and infusing with warm sesame oil; they are of 10 per cent. strength.

OLEATUM QUININÆ. N. F.

Oleate of Quinine [Oleat. Quin.]

This preparation contains 25 per cent. of quinine in oleic acid and is used as a local anesthetic.

OLEATUM VERATRINÆ. N. F.

Oleate of Veratrine [Oleat. Veratrin.]

This preparation contains 2 per cent. of veratrine in equal parts of olive oil and oleic acid, and is used as an anodyne and rubefacient. It should be used cautiously on account of the danger of systemic poisoning.

OLEOSACCHARA. N. F.

Oil-sugars

Elæosacchara.

The N. F. gives a general formula for triturating any prescribed oil (2 per cent.) with sugar. What the need is of such a title is not apparent.

OLEORESINA CUBEBÆ. N. F.

Oleoresin of Cubeb [Oleores. Cubeb.]

This is prepared by exhausting cubeb with alcohol and evaporating the extract. It is a dark greenish-brown liquid whose consistency varies according to the relative proportions of oil and resin in the original drug. After standing for some time it deposits a waxy and crystalline precipitate which should be rejected, only the liquid portion being used.

Dose, from five to ten minims (0.3–0.6 cc.).

OLEUM ÆTHEREUM. N. F.

Ethereal Oil [Ol. Æther.]

This is a "volatile liquid consisting of equal volumes of ether and of heavy oil of wine," prepared by distillation of alcohol with sulphuric acid. It is transparent, nearly colorless, has a specific gravity of 0.905 at 25° C., a peculiar aromatic odor, and a pungent taste. Preserve in small glass-stoppered bottles in a cool place. It is used in the preparation of compound spirit of ether (Hoffmann's anodyne).

OLEUM HYOSCYAMI COMPOSITUM. N. F.

Compound Oil of Hyoscyamus [Ol. Hyosc. Co.]

Balsamum Tranquillans.

This preparation is made from 0.2 per cent. of the oils of lavender, peppermint, rosemary, and thyme, with infused oil of hyoscyamus. It is used as an anodyne.

OLEUM PHENOLATUM. N. F.

Phenolated Oil [Ol. Phenol.]

Oleum Carbolatum; Carbolized Oil.

It is made by dissolving 5 per cent. of phenol in olive oil. Used externally.

OLEUM PHOSPHORATUM. N. F.

Phosphorated Oil [Ol. Phosphorat.]

This preparation is made by dissolving 1 Gm. of phosphorus in 90 times its weight of expressed oil of almond with the aid of water bath heat and adding to this solution enough ether to make 100 Gm. "It is a clear, yellowish liquid, having the odor of phosphorus and of ether, and free from undissolved particles." *N. F.* It affords an excellent means of administering phosphorus.

The *dose* is one minim (0.05 cc.).

OLEUM RICINI AROMATICUM. N. F.

Aromatic Castor Oil [Ol. Ricin. Arom.]

This is castor oil flavored with gluside (0.05 per cent.), oils of clove and cinnamon, vanillin, coumarin, and alcohol.

The *dose* is from one-half to one fluidounce (15–30 cc.).

OXYMEL SCILLÆ. N. F.

Oxymel of Squill [Oxymel Scill.]

This preparation is made from 1 part of vinegar of squill and 2 parts of clarified honey. Used as an expectorant.

The *dose* is one fluidrachm (4 cc.).

PASTÆ DERMATOLOGICÆ. N. F.

Dermatologic Pastes

These preparations are ointment-like mixtures of starch, dextrin, zinc oxide, sulphur, calcium carbonate, or other medicinal substances made into a paste with glycerin, soft soap, petrolatum, etc., medicated with antiseptic or astringent agents and used in the practice of dermatologists.

PASTA BETANAPHTHOLIS. N. F.

Betanaphthol Paste [Past. Betanaphthol.]

Pasta Naphtholis Lassar; Lassar's Naphthol Paste.

This preparation contains 10 per cent. of betanaphthol, 50 per cent. of sulphur, 20 per cent. of petrolatum, and 20 per cent. of soft soap.

PASTA DEXTRINATA. N. F.

Dextrinated Paste [Past. Dextrin.]

This preparation contains 33 per cent. white dextrin, 33 per cent. glycerin and water. It is used as a vehicle.

PASTA RESORCINOLIS FORTIS. N. F.

Strong Resorcinol Paste [Past. Resorcin. Fort.]

Lassar's Stronger Resorcinol Paste.

This preparation contains 20 per cent. of resorcinol, zinc oxide, and starch, together with 40 per cent. of light liquid petrolatum.

PASTA RESORCINOLIS MITIS. N. F.

Mild Resorcinol Paste [Past. Resorcin. Mit.]

Lassar's Mild Resorcinol Paste.

This preparation contains 10 per cent. of resorcinol with 25 per cent. each of zinc oxide and starch, and 40 per cent. of light liquid petrolatum.

PASTA ZINCI. N. F.

Zinc Paste [Past. Zinc.]

Lassar's Zinc Paste.

This preparation contains 2 per cent. of salicylic acid, 24 per cent. of zinc oxide and starch, and 50 per cent. of petrolatum. Used as an antiseptic and protective in skin diseases.

PASTA ZINCI MOLLIS. N. F.

Soft Zinc Paste [Past. Zinc Moll.]

Unna's Soft Zinc Paste.

This preparation contains 25 per cent. each of zinc oxide, precipitated calcium carbonate, linseed oil, and solution of calcium hydroxide (lime water).

PASTA ZINCI SULPHURATA. N. F.

Sulphurated Zinc Paste [Past. Zinc. Sulphur.]

Unna's Sulphurated Zinc Paste.

This preparation contains 15 per cent. of zinc oxide, 10 per cent. of precipitated sulphur, 5 per cent. of purified siliceous earth, and 70 per cent. of benzoinated lard. It is used as an antizymotic and protective.

PEPSINUM SACCHARATUM. N. F.

Saccharated Pepsin [Pepsin. Sacchar.]

This preparation is a 10 per cent. triturate of pepsin with sugar of milk.

The *dose* is from thirty to sixty grains (2–4 Gm.).

PETROXOLINA MEDICATA. N. F.

Medicated Petroxolins.

These are made by dissolving the indicated medicinal substances in liquid petroxolin. Contrary to a common belief, liquid petroxolin does not readily penetrate the skin and the chief use of these preparations is as local remedies.

PETROXOLINUM BETANAPHTHOLIS. N. F.

Betanaphthol Petroxolin [Petrox. Betanaphthol.]

This preparation is a 10 per cent. fresh solution of betanaphthol in liquid petroxolin.

PETROXOLINUM BITUMENIS SULPHONATI. N. F.

Sulphonated Bitumen Petroxolin

This contains 10 per cent. of ichthyol in liquid petroxolin.

PETROXOLINUM CADINUM. N. F.

Cade Petroxolin [Petrox. Cadin.]

This preparation is a 25 per cent. mixture of oil of cade and liquid petroxolin.

PETROXOLINUM CHLOROFORMI CAMPHORATUM. N. F.

Camphorated Chloroform Petroxolin [Petrox. Chlorof. Camph.]

This is a solution of 25 per cent. each of chloroform and camphor in liquid petroxolin.

PETROXOLINUM CREOSOTI. N. F.

Creosote Petroxolin [Petrox. Creosot.]

This is a mixture of creosote 20 per cent., and olive oil 5 per cent., in liquid petroxolin. It is used as an antiputrescent and antiseptic.

PETROXOLINUM EUCALYPTOLIS. N. F.

Eucalyptol Petroxolin [Petrox. Eucalyptol.]

This is a 20 per cent. solution of eucalyptol in liquid petroxolin.

PETROXOLINUM GUAIACOLIS. N. F.

Guaiacol Petroxolin [Petrox. Guaiacol.]

This is a mixture of guaiacol 20 per cent., olive oil 5 per cent., and liquid petroxolin.

PETROXOLINUM HYDRARGYRI. N. F.

Mercury Petroxolin [Petrox. Hydrarg. Mercury Petrox]

This preparation contains 30 per cent. of mercury extinguished with 13 per cent. of hydrous wool fat and 2 per cent. oleic acid, and solid petroxolin added to make 100 parts.

PETROXOLINUM IODI. N. F.

Iodine Petroxolin [Petrox. Iod. Iodine Petrox, 10 per cent.]

This contains 10 Gm. of iodine in 100 cc. of liquid petroxolin.

PETROXOLINUM IODI DILUTUM. N. F.

Diluted Iodine Petroxolin [Petrox. Iod. Dil. Iodine Petrox, 5 per cent.]

This preparation is a solution of 5 per cent. iodine in liquid petroxolin.

PETROXOLINUM LIQUIDUM. N. F.

Liquid Petroxolin [Petrox. Liq.]

Petrolatum Saponatum Liquidum; Liquid Petrox.

This preparation is made from light liquid petrolatum, oleic acid, stronger ammonia water, and 15 per cent. alcohol and perfumed with oil of lavender. It is a yellowish-brown liquid, miscible with ether, chloroform, petroleum benzin or acetone and producing an emulsion-like mixture when added to twice its volume of water. It is used as a basis for various medicated petroxolins.

PETROXOLINUM MENTHOLIS. N. F.

Menthol Petroxolin [Petrox. Menthol.]

This preparation contains 10 Gm. of menthol in 100 cc. of liquid petroxolin. It is used as a local anesthetic.

PETROXOLINUM METHYLIS SALICYLATIS. N. F.

Methyl Salicylate Petroxolin [Petrox. Methyl. Sal.]

This preparation is a solution of methyl salicylate, 20 per cent., in liquid petroxolin. It is used as an antirheumatic.

PETROXOLINUM PHENOLIS. N. F.

Phenol Petroxolin [Petrox. Phenol.]

This preparation is a 5 per cent. solution of phenol in liquid petroxolin.

PETROXOLINUM PHENOLIS CAMPHORATUM. N. F.

Camphorated Phenol Petroxolin [Petrox. Phenol. Camph.]

This contains 12.5 per cent. phenol and 37.5 per cent. camphor in liquid petroxolin.

PETROXOLINUM SPISSUM. N. F.

Solid Petroxolin [Petrox. Spiss.]

Petrolatum Saponatum Spissum; Solid Petrox.

This preparation is a mixture of 35 per cent. white wax, 20 per cent. light liquid petrolatum, 32 per cent. oleic acid, 3 per cent. oil of lavender, 5 per cent. alcohol, and 5 per cent. stronger ammonia water. It is used as a vehicle for ointments.

PETROXOLINUM SULPHURATUM. N. F.

Sulphurated Petroxolin [Petrox. Sulphur.]

This preparation is a mixture of 3 per cent. sublimed sulphur, 37 per cent. linseed oil, 30 per cent. oleic acid, in liquid petroxolin.

PETROXOLINUM SULPHURATUM COMPOSITUM. N. F.

Compound Sulphurated Petroxolin [Petrox. Sulphur. Co.]

This preparation is made from 10 per cent. sulphurated petroxolin, 10 per cent. oil of cade, 0.3 per cent. thymol, 3 per cent. eucalyptol, 30 per cent. oil of turpentine, and liquid petroxolin.

PHENOL IODATUM. N. F.

Iodized Phenol [Phenol. Iodat.]

This is made from iodine 20 per cent., phenol 60 per cent., and glycerin. It is an active germicide.

PILULÆ. N. F.

Pills

Pills are globular or ovoid dosage forms of medicinal substances intended for internal administration. Each pill weighs not less than 0.06 Gm., nor more than 0.5 Gm. If they weigh less than 0.06 Gm. and more than 0.02 Gm. each they are known as "*Granules*"; if the weight is less than 0.02 Gm., they are usually designated as "*Parvules.*" The ingredients are massed by the aid of selected excipients.

For the extemporaneous coating of pills by the pharmacist, formulas and working directions for the following methods are supplied: gelatin, sugar, cocoa, tolu, silver, and salol coatings. For the coating of the so-called "enteric pills," the use of salol is recommended. (See also *Pilulæ*, Part I.)

PILULÆ ALOES ET ASAFŒTIDÆ. N. F.

Pills of Aloe and Asafetida [Pil. Aloe et Asafœt.]

Each pill contains about 1½ grains each of aloe and asafetida.

The *dose* is one or two pills.

PILULÆ ASAFŒTIDÆ ET FERRI. N. F.

Pills of Aloe and Iron [Pil. Aloe et Ferr.]

Each pill contains about 1 grain each of aloe and exsiccated ferrous sulphate.

The *dose* is one or two pills.

PILULÆ ALOES ET MASTICHES. N. F.

Pills of Aloe and Mastic [Pil. Aloe et Mastich.]

Lady Webster Dinner Pill.

Each pill contains about 2 grains of aloe and ⅔ grain of mastic.
The *dose* is one pill.

PILULÆ ALOES ET MYRRHÆ. N. F.

Pills of Aloe and Myrrh [Pil. Aloe et Myrrh.]

Each pill contains about 1 grain of myrrh and 2 grains of aloe.
The *dose* is one pill.

PILULÆ ALOES ET PODOPHYLLI COMPOSITÆ. N. F.

Compound Pills of Aloe and Podophyllum [Pil. Aloe et Podoph. Co.]

Janeway's Pills.

Each pill contains about 1 grain of aloe, ½ grain of resin of podophyllum and ¼ grain each of extracts of belladonna and nux vomica.
The *dose* is one pill.

PILULÆ ALOES, HYDRARGYRI ET PODOPHYLLI. N. F.

Pills of Aloe, Mercury and Podophyllum [Pil. Aloe, Hydrarg. et Podoph.]

Pilulæ Triplices; Pilula Triplex; Triplex Pills.

Each pill contains about 2 grains of aloe, 1 grain of mass of mercury and ¼ grain of resin of podophyllum.
The *dose* is one pill.

PILULÆ ALOINI COMPOSITÆ. N. F.

Compound Pills of Aloin [Pil. Aloin Co.]

Each pill contains about ½ grain of aloin, ⅛ grain of resin of podophyllum and ¼ grain of extract of belladonna.
The *dose* is one pill.

PILULÆ ALOINI, STRYCHNINÆ ET BELLADONNÆ. N. F.

Pills of Aloin, Strychnine and Belladonna [Pil. A., S. et B.]

Each pill contains about ⅕ grain of aloin, ⅛ grain of extract of belladonna and 1–125th grain of strychnine.
The *dose* is one or two pills.

PILULÆ ALOINI, STRYCHNINÆ ET BELLADONNÆ COMPOSITÆ. N. F.

Compound Pills of Aloin, Strychnine and Belladonna [Pil. A., S. et B. Co.]

These are the same as the preceding with the addition of ½ grain of cascara sagrada in each pill.
The *dose* is one or two pills.

PILULÆ ANTIPERIODICÆ. N. F.

Antiperiodic Pills [Pil. Antiperiod.]

Warburg's Pills.

Each pill contains 2 grains of aloes, ½ grain of rhubarb, ½ grain of angelica seed, ¼ grain each of inula, of saffron, and fennel, ⅛ grain of zeodoary root, of cubeb, myrrh, agaric and camphor, and 1½ grains of quinine sulphate, with a sufficient quantity of extract of gentian to form a mass.
The *dose* is one to three pills one to three times daily.

PILULÆ ANTIPERIODICÆ SINE ALOE. N. F.

Antiperiodic Pills without Aloes [Pil. Antiperiod. s. Aloe.]

Warburg's Pills without Aloes.

The formula is similar to that for the preceding pill, but the extract of aloes is omitted.
The *dose* is one to three pills.

PILULÆ CATHARTICÆ VEGETABILES. N. F.

Vegetable Cathartic Pills [Pil. Cathart. Veget.]

Each pill contains 1 grain compound extract of colocynth, ½ grain extract of hyoscyamus, ⅓ grain of resin of jalap, and ¼ grain each of extract of leptandra and resin of podophyllum.
The *dose* is two pills.

PILULÆ DIGITALIS, SCILLÆ ET HYDRARGYRI. N. F.

Pills of Digitalis, Squill and Mercury [Pil. Digit., Scill. et Hydrarg.]

Niemeyer Pills for Dropsy; Guy's Pills.

Each pill contains 1 grain each of digitalis, squill, and mass of mercury with clarified honey. Used as a diuretic. They must be carefully distinguished from Niemeyer's pill for *phthisis* (see *Pilulæ Opii Digitalis et Quininæ*).
The *dose* is one pill.

PILULÆ FERRI IODIDI. N. F.

Pills of Ferrous Iodide [Pil. Ferr. Iod.]

Blancard's Pills.

These are essentially the same as the pills of the U. S. IX. Each pill represents 1 grain of ferrous iodide.
Dose, one to three pills.

PILULÆ FERRI, QUININÆ, ALOES ET NUCIS VOMICÆ. N. F.

Pills of Iron, Quinine, Aloes and Nux Vomica [Pil. Ferr., Quin., Aloe et Nuc. Vom.]

Pilulæ Quadruplices; Quadruplex Pills; Pilulæ Ferri et Quininæ Compositæ.

Each pill contains 1 grain each of dried ferrous sulphate, quinine sulphate, and aloes, ¼ grain of extract of nux vomica, and enough extract of gentian to mass.
The *dose* is one pill.

PILULÆ FERRI, QUININÆ, STRYCHNINÆ ET ARSENI FORTIORES. N. F. Pilulæ Metallorum, N. F. III

Stronger Pills of Iron, Quinine, Strychnine and Arsenic [Pil. Ferr., Quin., Strych. et Arsen. Fort.]

Pilulæ Metallorum; Metallic Pills; Pilulæ Metallorum Amaræ; Bitter Metallic Pills.

Each pill contains 1 grain each of reduced iron and quinine sulphate, and 1–20th grain each of

strychnine and arsenic trioxide, massed with clarified honey.
The *dose* is one pill.

PILULÆ FERRI, QUININÆ, STRYCHNINÆ ET ARSENI MITES. N. F.

Mild Pills of Iron, Quinine, Strychnine, and Arsenic [Pil. Ferr., Quin., Strych. et Arsen. Mit.]

Aitken Tonic Pills.

Each pill contains ⅔ grain of reduced iron and 1 grain of quinine sulphate, and one-fiftieth grain each of strychnine and arsenic trioxide massed with clarified honey.
The *dose* is one pill.

PILULÆ LAXATIVÆ COMPOSITÆ. N. F.

Compound Laxative Pills [Pil. Lax. Co.]

Each pill contains ⅕ grain aloin, 1–125th grain strychnine, ⅛ grain extract of belladonna leaves, 1–16th grain of ipecac, licorice and syrup to mass. Used as a laxative.
The *dose* is one or two pills.

PILULÆ OPII, DIGITALIS ET QUININÆ N. F.

Pills of Opium, Digitalis, and Quinine [Pil. Opii, Digit. et Quin.]

Niemeyer Pills for Phthisis.

Each pill contains ⅕ grain of opium and 1 grain each of digitalis and quinine.
The *dose* is one pill.

PILULÆ OPII ET CAMPHORÆ. N. F.

Pills of Opium and Camphor [Pil. Opii et Camph.]

Each pill contains 1 grain of powdered opium and 2 grains of camphor.
The *dose* is one pill.

PILULÆ OPII ET PLUMBI. N. F.

Pills of Opium and Lead [Pil. Opii et Plumb.]

Each pill contains 1 grain of powdered opium and 1 grain of lead acetate.
The *dose* is one pill.

PILULÆ RHEI. N. F.

Pills of Rhubarb [Pil. Rhei]

Each pill contains 3 grains of rhubarb and 1 grain of soap.
The *dose* is one pill.

PILULÆ RHEI COMPOSITÆ. N. F.

Compound Pills of Rhubarb [Pil. Rhei Co.]

These are practically the same as the compound rhubarb pills of the U. S. IX; each pill contains, approximately, 2 grains of rhubarb, 1½ of aloes and 1 grain of myrrh.
The *dose* is two or three pills.

PULVIS ACETANILIDI COMPOSITUS. N. F.

Compound Acetanilid Powder [Pulv. Acetan. Co.]

A mixture of acetanilid, 70 Gm., caffeine, 10 Gm., and sodium bicarbonate, 20 Gm.
The *dose* is five grains (0.3 Gm.).

PULVIS ALOES ET CANELLÆ. N. F.

Powder of Aloes and Canella [Pulv. Aloe et Canell.]

Hiera Picra.

It contains 80 per cent. of purified aloes and 20 per cent. of powdered canella.
The *dose* is five grains (0.3 Gm.).

PULVIS ANTIMONIALIS. N. F.

Antimonial Powder [Pulv. Antimon.]

James' Powder.

A mixture of antimony oxide, 33 per cent., and precipitated calcium phosphate, 67 per cent.
The *dose* is three grains (0.2 Gm.).

PULVIS ANTISEPTICUS. N. F.

Antiseptic Powder [Pulv. Antisept.]

Soluble Antiseptic Powder; Pulvis Antisepticus Solubilis.

This is practically a mixture of 86.6 parts of boric acid and 12.5 parts of zinc sulphate perfumed with traces of salicylic acid, phenol, eucalyptol, menthol and thymol.

PULVIS AROMATICUS. N. F.

Aromatic Powder [Pulv. Arom.]

This is the same as the article formerly recognized by the U. S. IX. It is a mixture of 35 parts each of cinnamon and ginger with 15 parts each of cardamom and nutmeg.
The *dose* is from ten to twenty grains (0.6–1.2 Gm.).

PULVIS AROMATICUS RUBEFACIENS. N. F.

Rubefacient Spice Powder [Pulv. Arom. Rubefac.]

Consists of clove, 30 per cent., Saigon cinnamon, 30 per cent., ginger, 20 per cent., and capsicum, 20 per cent.
"NOTE.—When rubefacient spice powder is needed for *Spice Poultice*, place the required quantity in a flat muslin bag and moisten it with either diluted alcohol or vinegar, previously heated." *N. F.*
It is used only externally and should not be confused with the preceding preparation.

PULVIS CRETÆ AROMATICUS. N. F.

Aromatic Powder of Chalk [Pulv. Cret. Arom.]

It contains 8 per cent. of cinnamon, 6 per cent. of nutmeg, 3 per cent. of clove, 2 per cent. of cardamom seed, 25 per cent. of prepared chalk and 56 per cent. of sugar. It is used in *diarrhea*.
The *dose* is thirty to sixty grains (2–4 Gm.).

PULVIS CRETÆ ET OPII AROMATICUS, N. F. Pulvis Cretæ Aromaticus cum Opio, N. F. III

Aromatic Powder of Chalk and Opium [Pulv. Cret. et Opii Arom.]

This is aromatic chalk powder containing 2.5 per cent. of powdered opium.
The *dose* is from ten to thirty grains (0.6–2 Gm.).

PULVIS HYDRARGYRI CHLORIDI MITIS ET JALAPÆ. N. F.

Powder of Mild Mercurous Chloride and Jalap [Pulv. Hydrarg. Chlor. Mit. et Jalap.]

Calomel and Jalap.

This is a mixture of 34 Gm. of mild chloride of mercury and 66 Gm. of jalap.

The *dose* is ten grains (0.65 Gm.).

PULVIS MYRICÆ COMPOSITUS. N. F.

Compound Powder of Bayberry [Pulv. Myric. Co.]

Composition Powder.

It contains 60 per cent. of bayberry bark, 30 per cent. of ginger, 5 per cent. of capsicum, and 5 per cent. of clove.

The *dose* is fifteen grains (1 Gm.).

PULVIS PANCREATINI COMPOSITUS. N. F.

Compound Pancreatin Powder [Pulv. Pancreat. Co.]

Peptonizing Powder.

This is a mixture of 20 Gm. of pancreatin and 80 Gm. of sodium bicarbonate. Twenty-five grains of this powder are sufficient to peptonize 1 pint of fresh cow's milk. Used for preparing "predigested" foods.

PULVIS RHEI ET MAGNESIÆ ANISATUS. N. F.

Anisated Powder of Rhubarb and Magnesia [Pulv. Rhei et Magnes. Anis.]

Compound Anise Powder.

It contains 35 per cent. of powdered rhubarb and 65 per cent. of heavy magnesia, with anethol and alcohol. It is laxative and carminative.

The *dose* for infants is five grains (0.3 Gm.).

PULVIS TALCI COMPOSITUS. N. F.

Compound Powder of Talc [Pulv. Talc. Co.]

Boro-Salicylated Powder of Talc; Pulvis Talci Salicylicus.

It contains 3 per cent. of salicylic acid, 10 per cent. of boric acid, and 87 per cent. of talc, all in very fine powder.

SALIA EFFERVESCENTIA. N. F.

Granular Effervescent Salts

Two general processes are given for preparing effervescent salts, the one to be used being determined by the quantity of material taken. The products, however, from both processes should be identical. The citric acid should be uneffloresced crystals, powdered immediately before using; the other ingredients should be dried at a temperature not exceeding 50° C. The granulation is performed in an oven or on a water bath. The dry granular powder is passed through a No. 6 tinned-iron sieve, and immediately transferred to dry bottles of containers, and hermetically sealed.

SAL CAROLINUM FACTITIUM. N. F.

Artificial Carlsbad Salt [Sal. Carol. Fact.]

Two forms of this mixture are described. The first, a dry amorphous form, contains 2 Gm. of potassium sulphate, 18 Gm. of sodium chloride, 36 Gm. of sodium bicarbonate and 100 Gm. of sodium sulphate dried to a constant weight of about 100 Gm., there being a loss of a corresponding amount of water. The second form is crystalline; it contains the same ingredients in a crystallized state, making a total of about 180 Gm.

The *dose* would be about one or two drachms (4–8 cc.) but it is rarely used except in the effervescent form (see below).

SAL CAROLINUM FACTITIUM EFFERVESCENS. N. F.

Effervescent Artificial Carlsbad Salt [Sal. Carol. Fact. Eff.]

It contains 26.6 per cent. of artificial Calsbad salt, with sodium bicarbonate, tartaric acid, and citric acid.

The *dose* is from one to two drachms (4–8 Gm.).

SAL KISSINGENSE FACTITIUM. N. F.

Artificial Kissingen Salt [Sal Kissingen. Fact.]

It is made from 1.7 parts of potassium chloride, 35.7 parts of sodium chloride, 12 parts of magnesium sulphate and 10.7 parts of sodium bicarbonate. Twenty-four grains of this salt dissolved in 6½ fluidounces of water represents an equal volume of Kissingen water (Rakoczi).

SAL KISSINGENSE FACTITIUM EFFERVESCENS. N. F.

Effervescent Artificial Kissingen Salt [Sal Kissingen. Fact. Eff.]

It contains 40 per cent. of artificial Kissingen salt, with sodium bicarbonate, tartaric acid, and citric acid.

The *dose* is eighty grains (5.5 Gm.).

SAL LITHII CITRATIS EFFERVESCENS. N. F.

Effervescent Salt of Lithium Citrate [Sal. Lith. Cit. Eff.]

Lithii Citras Effervescens (*U. S. P. VIII*); Effervescent Lithium Citrate.

This preparation contains 5 per cent. lithium citrate, and is prepared according to the general formula. It is used as an antilithic and diuretic.

The *dose* is two drachms (8 Gm.).

SAL MAGNESII SULPHATIS EFFERVESCENS. N. F.

Effervescent Magnesium Sulphate [Sal. Mag. Sulph. Eff.]

Magnesii Sulphas Effervescens.

This represents 50 per cent. of Epsom salt with sodium bicarbonate, citric and tartaric acids.

The *dose* is usually about one-half an ounce (15 Gm.).

SAL POTASSII BROMIDI EFFERVESCENS COMPOSITUM. N. F.

Compound Effervescent Salt of Potassium Bromide [Sal Pot. Brom. Eff. Co.]

Pulvis Potassii Bromidi Effervescens cum Caffeina; Effervescent Potassium Bromide with Caffeine.

This preparation contains 0.8 per cent. caffeine, 8.3 per cent. potassium bromide, and 4.2 per cent.

lithium carbonate with sodium bicarbonate and citric and tartaric acids.

The *dose* is from one to three drachms (4–11 Gm.).

SAL VICHYANUM FACTITIUM. N. F.

Artificial Vichy Salt [Sal Vichy. Fact.]

This is a mixture of 846 Gm. of sodium bicarbonate, 38.5 Gm. of potassium carbonate, 80 Gm. of magnesium sulphate and 77 Gm. of sodium chloride. "A solution of 1 Gm. of this preparation in 200 cc. of water is similar to an equal volume of Vichy water (Grande Grille Spring) in its main constituents." *N. F.*

SAL VICHYANUM FACTITIUM EFFERVESCENS. N. F.

Effervescent Artificial Vichy Salt [Sal Vichy. Fact. Eff.]

It contains 25 per cent. artificial Vichy salt, with sodium bicarbonate, tartaric acid, and citric acid. Seven grains of this powder dissolved in 6½ fluidounces of water represents an equal volume of Vichy water (Grande Grille). an antacid.

The *dose* is from one to two drachms.

SEVUM BENZOINATUM. N. F.

Benzoinated Suet [Sev. Benz.]

Prepared by digesting suet with 3 per cent. of powdered benzoin.

SOLUTIO MASTICHES CHLOROFORMICA COMPOSITA. N. F.

Compound Chloroformic Solution of Mastic [Sol. Mastic. Chlorof. Co.]

Pulp Capping Varnish.

A solution of 3 per cent. each of mastic and balsam of Peru in chloroform. It is used in dentistry.

SOLUTIO RESINÆ CHLOROFORMICA. N. F.

Chloroformic Solution of Rosin [Sol. Resin. Chlorof.]

A 20 per cent. solution of rosin in chloroform. "Preserve in amber-colored, cork-stoppered bottles." *N. F.* It is used as a dental varnish.

SPECIES EMOLLIENTES. N. F.

Emollient Species [Spec. Emoll. Emollient Cataplasm]

It is made from equal parts of althæa leaves, mallow leaves, melilot, matricaria, and linseed. Emollient; used for making an emollient poultice, by adding to it a suitable quantity of hot water.

SPECIES LAXATIVÆ. N. F.

Laxative Species [Spec. Lax.]

Species Laxantes; St. Germain Tea.

It contains 40 per cent. of cut senna, 25 per cent. of elder flowers, 12.5 per cent. of bruised fennel, 12.5 per cent. of bruised anise, and 10 per cent. of potassium bitartrate.

The *dose* is from twenty to sixty grains (1.3–4 Gm.).

SPECIES PECTORALES. N. F.

Pectoral Species [Spec. Pect.]

Species ad Infusum Pectorale; Breast Tea.

It contains 8 parts of althæa, peeled, 4 parts of coltsfoot leaves, 3 parts of Russian glycyrrhiza, peeled, 2 parts of anise, 2 parts of mullein flowers, and 1 part of orris root. Used as a pectoral.

The *dose* is one drachm (4 Gm.).

SPIRITUS ACIDI FORMICI. N. F.

Spirit of Formic Acid [Sp. Ac. Formic.]

Spiritus Formicarum; Spirit of Ants.

It contains 4 per cent. of formic acid in alcohol and distilled water.

The *dose* is one fluidrachm (4 cc.).

SPIRITUS ÆTHERIS. N. F.

Spirit of Ether [Sp. Æth.]

Hoffmann's Drops.

An alcoholic solution of ether (32.5 per cent.).

The *dose* is from one to two fluidrachms (4–8 cc.).

SPIRITUS ÆTHERIS COMPOSITUS. N. F.

Compound Spirit of Ether [Sp. Æth. Co.]

Hoffmann's Anodyne.

This preparation contains 2.5 per cent. ethereal oil in a solution of ether in alcohol (1:2).

The *dose* is from one to two fluidrachms (4–8 cc.).

SPIRITUS AMMONIÆ ANISATUS. N. F.

Anisated Spirit of Ammonia [Sp. Ammon. Anis.]

Liquor Ammoniæ Anisatus; Anisated Solution of Ammonia.

This preparation is a solution of anethol, 3 per cent., in a mixture of 20 per cent. ammonia water in alcohol.

The *dose* is from fifteen minims to forty-five minims (1–3 cc.).

SPIRITUS AMYGDALÆ AMARÆ. N. F.

Spirit of Bitter Almond [Sp. Amygd. Amar.]

A 10 per cent. solution of the oil of bitter almond in 80 per cent. alcohol. "This spirit is intended for medicinal use; it must not be used for flavoring foods." *N. F.*

Dose, from three to eight minims (0.2–0.5 cc.).

SPIRITUS CARDAMOMI COMPOSITUS N. F.

Compound Spirit of Cardamom [Sp. Card. Co.]

It is made from the oils of cardamom, orange, cinnamon, clove, and caraway, and anethol dissolved in alcohol. Used for flavoring.

SPIRITUS MYRCIÆ COMPOSITUS. N. F.

Compound Spirit of Myrcia [Sp. Myrciæ Co.]

A hydroalcoholic solution of oils of bay, orange, and allspice. It resembles *Bay Rum.*

SPIRITUS ODORATUS. N. F.

Perfumed Spirit [Sp. Odorat.]

Aqua Cologniensis; Cologne Water.

A hydroalcoholic solution of oil of bergamot, lemon, rosemary, lavender, orange flowers, and acetic ether. Used as a perfume.

SPIRITUS OLEORUM VOLATILIUM. N. F.

Spirits of Volatile Oils

Any spirit of a volatile oil for which no specific formula is provided may be prepared by dissolving 6.5 parts of the oil in 93.5 parts of alcohol.

SPIRITUS SINAPIS. N. F.

Spirit of Mustard [Sp. Sinap.]

This spirit contains 2 per cent. of volatile oil of mustard in alcohol. Used as a counter-irritant.

SPIRITUS VANILLINI COMPOSITUS. N. F.

Compound Spirit of Vanillin [Sp. Vanil. Co.]

This preparation contains vanillin, 20 per cent., oil of orange, 5 per cent., oil of cardamom, 1 per cent., and oil of cinnamon, 0.5 per cent., in alcohol. Used as a flavoring agent.

STILI MEDICAMENTORUM. N. F.

Stili Dilubiles, N. F. IV

Paste Pencils; Unna Pencils.

These are preparations in the form of a pencil the medicinal agent incorporated in a paste made from starch, dextrin, tragacanth, sugar, and water. They are rolled into cylinders 5 mm. thick and 5 cm. long. They are used in dermatological practice. The N. F. gives one formula as exemplar (see succeeding article).

STILI ACIDI SALICYLICI. N. F.

Salicylic Acid Pencil [Stil. Acid. Salicyl.] Dilub.]

Stilus Acidi Salicylici Dilubilis.

These pencils contain 10 per cent. of salicylic acid, with tragacanth, starch, dextrin, sugar, and distilled water.

SULPHURIS IODIDUM. N. F.

Sulphur Iodide [Sulphur. Iod.]

Prepared by fusing together 20 Gm. washed sulphur and 80 Gm. of iodine. An assay process is included. It occurs in brittle masses having a crystalline fracture and a grayish-black, metallic luster. Almost insoluble in water; soluble in about 60 parts of glycerin; very soluble in carbon disulphide. Alcohol, ether, or an aqueous solution of potassium iodide dissolves the iodine, leaving the sulphur. Continued boiling with water vaporizes all of the iodine, leaving about 20 per cent. of sulphur as a residue. It is used externally.

SUPPOSITORIA BOROGLYCERINI. N. F.

Suppositories of Boroglycerin [Suppos. Boroglycer.]

The suppositories contain glycerinated gelatin, glycerin, and glycerite of boroglycerin, 30 per cent.

SYRUPUS ALLII. N. F.

Syrup of Garlic [Syr. Allii]

Prepared from garlic (20 per cent.), sugar, and diluted acetic acid.

The *dose* is one fluidrachm (4 cc.).

SYRUPUS ALTHÆÆ. N. F.

Syrup of Althæa [Syr. Althæ.]

Prepared from althæa (5 per cent.), and contains 10 per cent. of glycerin and 3 per cent. of alcohol.

"Preserve the syrup in well-stoppered, completely filled bottles, in a cool place." *N. F.*

The *dose* is one fluidrachm (4 cc.).

SYRUPUS AMMONII HYPOPHOSPHITIS. N. F.

Syrup of Ammonium Hypophosphite [Syr. Ammon. Hypophos.]

One fluidrachm (4 cc.) of this syrup contains two grains (0.125 Gm.) of ammonium hypophosphite. It is flavored with compound spirit of vanillin.

The *dose* is from one to two fluidrachms (4–8 cc.).

SYRUPUS ASARI COMPOSITUS. N. F.

Compound Syrup of Asarum [Syr. Asar. Co.]

It is made from asarum root, alcohol, cochineal, potassium carbonate, fluidextract of ipecac, sugar, and water. About 3.5 grains of asarum and ⅙ grain of ipecac are represented by 1 fluidrachm of finished syrup.

The *dose* is given in the N. F. as one fluidrachm (4 cc.) but an adult would require from one-half to one fluidounce (15–30 cc.) to produce any obvious effect.

SYRUPUS BROMIDORUM. N. F.

Syrup of the Bromides [Syr. Bromidor.]

It is made from potassium, sodium, ammonium, calcium, and lithium bromides, tincture of vanilla, compound tincture of cudbear, compound syrup of sarsaparilla and syrup. About 15 grains of the mixed bromides are contained in 1 fluidrachm of the finished syrup. Used as a nerve sedative.

The *dose* is one fluidrachm (4 cc.).

SYRUPUS CACAO. N. F.

Syrup of Cocoa [Syr. Cacao]

Syrup of Chocolate; Chocolate Syrup.

This is a pleasant flavoring agent made of chocolate, tincture of vanilla and sugar.

SYRUPUS CALCII ET SODII HYPOPHOSPHITUM. N. F.

Syrup of Calcium and Sodium Hypophosphites [Syr. Calc. et Sod. Hypophos.]

About 2 grains each of calcium and sodium hypophosphites, with hypophosphorous acid, sugar and water, are contained in 1 fluidrachm of the finished syrup.

The *dose* is from one to four fluidrachms (4–15 cc.).

SYRUPUS CALCII HYPOPHOSPHITIS. N. F.

Syrup of Calcium Hypophosphite [Syr. Calc. Hypophos.]

It is made from calcium hypophosphite, hypophosphorous acid, sugar, and water. About 2 grains of calcium hypophosphite are contained in 1 fluidrachm of the finished syrup.

The *dose* is from one to four fluidrachms (4-15 cc.).

SYRUPUS CALCII IODIDI. N. F.

Syrup of Calcium Iodide [Syr. Calc. Iodid.]

It is made from iodine, iron wire, precipitated calcium carbonate, sugar, distilled water, and syrup. About 5 grains of calcium iodide are contained in 1 fluidrachm of the finished syrup. This may be used for the same purpose as the other iodides, but is by some believed to be especially valuable in *asthma*.

The *dose* is from one-half to one fluidrachm (2-4 cc.).

SYRUPUS CALCII LACTOPHOSPHATIS. N. F.

Syrup of Calcium Lactophosphate [Syr. Calc. Lactophos.]

The formula for this is the same as that of the U. S. IX. It contains the equivalent of about 1.5 grains of calcium phosphate in each fluidrachm.

The *dose* is from two to four fluidrachms (8-15 cc.).

SYRUPUS CALCII LACTOPHOSPHATIS ET FERRI. N. F. Syrupus Calcii Lactophosphatis cum Ferro, N. F. III

Syrup of Calcium Lactophosphate and Iron [Syr. Calc. Lactophos. et Ferr.]

It is made from ferrous lactate, potassium citrate, water, and syrup of calcium lactophosphate. About ½ grain of ferrous lactate is contained in 1 fluidrachm of the finished syrup.

The *dose* is from one to four fluidrachms (4-15 cc.).

SYRUPUS CINNAMOMI. N. F.

Syrup of Cinnamon [Syr. Cinnam.]

It is made from cinnamon, alcohol, sugar, and cinnamon water. It represents 10 per cent. of the water soluble constituents of cinnamon. It is chiefly used as a flavoring agent.

The official *dose* is one fluidrachm (4 cc.).

SYRUPUS ERIODICTYI AROMATICUS. N. F.

Aromatic Syrup of Eriodictyon [Syr. Eriodict. Arom.]

Aromatic Spirit of Yerba Santa; Syrupus Corrigens.

This represents 3.2 per cent. of fluidextract of eriodictyon, flavored with compound tincture of cardamom, the oils of sassafras, lemon, and clove, alcohol, sugar, and water. Used as a vehicle, especially for quinine.

The *dose* is two fluidrachms (8 cc.).

SYRUPUS FERRI, QUININÆ ET STRYCHNINÆ PHOSPHATUM. N. F.

Syrup of the Phosphates of Iron, Quinine, and Strychnine [Syr. Ferr., Quin. et Strych. Phos.]

Easton's Syrup.

Each fluidrachm of this contains approximately 1.2 grains of soluble iron phosphate, 1.6 of quinine phosphate, and 1-60th of a grain of strychnine phosphate.

The *dose* is from one to two fluidrachms (4-8 cc.).

SYRUPUS FERRI SACCHARATI SOLUBILIS. N. F.

Syrup of Soluble Saccharated Iron [Syr. Ferr. Sacch. Sol.]

Syrupus Ferri Oxydati Solubilis; Syrup of Saccharated Oxide of Iron; Syrup of Soluble Oxide of Iron.

It is made from distilled water and syrup. About ¾ grain of metallic iron is represented in one fluidrachm of this syrup.

The *dose* is from one to three fluidrachms (4-12 cc.).

SYRUPUS FICORUM COMPOSITUS. N. F.

Compound Syrup of Figs [Syr. Ficor. Co.]

This unfortunately named syrup is prepared from figs, fluidextract of senna, aromatic fluidglycerate of cascara sagrada, oil of fennel, spirit of peppermint, sugar, and water. Each fluidrachm represents 12 grains of senna and 4.5 minims of fluidglycerate of cascara.

The *dose* is from one to two fluidrachms (4-8 cc.).

SYRUPUS GLYCYRRHIZÆ. N. F.

Syrup of Glycyrrhiza [Syr. Glycyrrh.]

Syrup of Licorice.

It is made from fluidglycerate of licorice and syrup. About 15 grains of glycyrrhiza root are represented in 1 fluidrachm of the finished syrup. It is used as a vehicle.

The *dose* is two fluidrachms (8 cc.).

SYRUPUS HYPOPHOSPHITUM. N. F.

Syrup of Hypophosphites [Syr. Hypophos.]

The formula for this is the same as that of the U. S. IX. It contains in each fluidrachm approximately 2.7 grains of calcium hypophosphite and 0.9 grains of each of sodium and potassium hypophosphites.

The *dose* is from two to four fluidrachms (8-15 cc.).

SYRUPUS HYPOPHOSPHITUM COMPOSITUS. N. F.

Compound Syrup of Hypophosphites [Syr. Hypophos. Co.]

One fluidrachm of this preparation contains 2 grains of calcium hypophosphite, one grain each of potassium and sodium hypophosphites, ⅛ grain each of ferric and manganese hypophosphites, 1-16th grain of quinine, and 1-140th grain of strychnine with sodium citrate, diluted hypophosphorous acid, in a vehicle of glycerin and syrup. It is a widely prescribed, but useless, concoction.

The *dose* is two to four fluidrachms (8-15 cc.).

SYRUPUS IODOTANNICUS. N. F.

Syrup of Iodotannin [Syr. Iodotan.]

This syrup is made from 0.27 per cent. of iodine and 0.54 per cent. of tannin. As the iodine undergoes chemical change, the syrup does not represent the therapeutic virtue of free iodine.

The *dose* is one fluidrachm (4 cc.).

SYRUPUS IPECACUANHÆ ET OPII. N. F.

Syrup of Ipecac and Opium [Syr. Ipecac. et Opii.]

Syrup of Dover's Powder.

It is made from the tincture of ipecac and opium, with spirit of cinnamon, cinnamon water, and syrup. Five grains of Dover's powder are represented by 1 fluidrachm of finished syrup.

The *dose* is one fluidrachm (4 cc.).

SYRUPUS KRAMERIÆ. N. F. (U. S. P. VIII)

Syrup of Krameria [Syr. Kramer.]

This is made with 45 per cent. fluidextract of krameria and syrup.

The *dose* is one fluidrachm (4 cc.).

SYRUPUS MANNÆ. N. F.

Syrup of Manna [Syr. Mann.]

This syrup contains about 12.5 per cent. of manna with sugar, alcohol, and water.

The *dose* is two fluidrachms (8 cc.).

SYRUPUS PHOSPHATUM COMPOSITUS. N. F.

Compound Syrup of the Phosphates [Syr. Phos. Co.]

Chemical Food.

This syrup represents 50 per cent., by volume, of compound solution of the phosphates in a vehicle of glycerin and syrup colored with cudbear.

The apparently grandiose synonym is not so fanciful as it would seem for the composition contains the essential bases, calcium, potassium, sodium and iron, as well as the equally essential phosphoric acid radical. As, however, it is difficult to conceive of a condition, short of actual starvation, in which there would be a lack of all of these mineral elements the composition is not one which seems to us to be scientifically desirable.

The *dose* is from one to two fluidrachms (4–8 cc.).

SYRUPUS PHOSPHATUM CUM QUININA ET STRYCHNINA. N. F. Syrupus Hydrochlorophosphatum, N. F. III

Syrup of Phosphates with Quinine and Strychnine [Syr. Phos. c. Quin. et Strych.]

Compound Syrup of Hydrochlorophosphates.

One fluidrachm of this syrup represents ¼ grain of quinine hydrochloride, 1–125th grain of strychnine nitrate with 30 minims of compound solution of the phosphates.

The *dose* is from one to two fluidrachms (4–8 cc.).

SYRUPUS PINI ALBÆ COMPOSITUS. N. F.

Compound Syrup of White Pine [Syr. Pin. Alb. Co.]

Syrupus Pini Strobi Compositus, *N. F. IV.*

This syrup is made from white pine bark, wild cherry bark, aralia, balsam poplar buds, sanguinaria, sassafras, cudbear, chloroform, oil of sassafras, sugar, alcohol, water, and syrup.

The *dose* is from one to two fluidrachms (4–8 cc.).

SYRUPUS PINI ALBÆ COMPOSITUS CUM MORPHINA. N. F.

Compound Syrup of White Pine with Morphine [Syr. Pin. Strob. c. Morph.]

Syrupus Pini Strobi Compositus, *N. F. IV.*

This syrup is made by dissolving 0.4 Gm. of morphine sulphate in 1000 cc. of compound syrup of white pine. It contains, therefore, about one-fortieth grain of morphine in each fluidrachm. It is an undesirable preparation as being not only of little therapeutic value but of encouraging the improper use of morphine.

The *dose* is from one-half to two fluidrachms (2–8 cc.).

SYRUPUS QUINIDINÆ. N. F.

Syrup of Quinidine [Syr. Quinid.]

Bitterless Syrup of Quinidine.

It is made from quinidine, oil of orange, and syrup. About 2 grains of quinidine is contained in 1 fluidrachm of finished syrup. Shake well before dispensing.

The *dose* is from one to two fluidrachms (4–8 cc.).

SYRUPUS RHAMNI CATHARTICÆ. N. F.

Syrup of Rhamnus Cathartica [Syr. Rham. Cathart.]

Syrup of Buckthorn Berries; Syrupus Spinæ Cervinæ.

This syrup contains 20 per cent. of fluidextract of buckthorn berries with 0.02 per cent. each of oils of fennel and cinnamon in syrup.

The *dose* is from one to two fluidrachms (4–8 cc.).

SYRUPUS ROSÆ. N. F.

Syrup of Rose [Syr. Ros.]

This syrup is made with 12.5 per cent. of fluidextract of rose and 1 per cent. diluted sulphuric acid. It is used as a flavoring vehicle.

SYRUPUS RUBI. N. F.

Syrup of Rubus [Syr. Rubi]

This syrup contains 25 per cent. of fluidextract of rubus with syrup. It is used as an astringent.

The *dose* is from one to two fluidrachms (4–8 cc.).

SYRUPUS RUBI IDÆI. N. F.

Syrup of Raspberry [Syr. Rubi Id.]

This is made with raspberry juice and sugar. It is heated to the boiling point and filtered while hot. "Preserve the product in well-stoppered bottles in a cool dark place." *N. F.* It is used as a flavoring agent.

SYRUPUS SENNÆ AROMATICUS. N. F.

Aromatic Syrup of Senna [Syr. Senn. Arom.]

It is made from fluidextract of senna, jalap, rhubarb, cinnamon, clove, nutmeg, oil of lemon, sugar, and diluted alcohol. About 7½ grains of senna, 3 grains of jalap, and 1 grain of rhubarb are contained in 1 fluidrachm of finished syrup.

The *dose* is two fluidrachms (8 cc.).

SYRUPUS STILLINGIÆ COMPOSITUS. N. F.

Compound Syrup of Stillingia [Syr. Stilling. Co.]

It is made from compound fluidextract of stillingia, sugar, and water. About 15 minims of compound fluidextract of stillingia are represented by 1 fluidrachm of the finished syrup. A useless relic of ancient superstition.

The official *dose* is one fluidrachm (4 cc.).

SYRUPUS THYMI. N. F.

Syrup of Thyme [Syr. Thymi]

This is a mixture of 20 parts of fluidextract of thyme and 80 parts of simple syrup.

The *dose* is from one to two fluidrachms (4–8 cc.).

SYRUPUS THYMI COMPOSITUS. N. F.

Compound Syrup of Thyme [Syr. Thymi Co.]

Each fluidrachm of this contains about 2 grains of ammonium bromide in syrup of thyme.

The *dose* is from one to two fluidrachms (4–8 cc.).

SYRUPUS TRIFOLII COMPOSITUS. N. F.

Compound Syrup of Trifolium [Syr. Trifol. Co.]

This contains 30 per cent. of the compound fluidextract of trifolium flavored with oils of sassafras and anise and methyl salicylate.

The *dose* is from two to four fluidrachms (8–15 cc.).

TABELLÆ. N. F.

Tablets

These are discs of two classes; tablet triturates and compressed tablets. The former are made by triturating together the active ingredient with sugar or some other diluent and moistening with some volatile liquid which permits the tablets to be molded into the desired shape and subsequently dried. They are friable and dissolve or disintegrate rapidly when dropped into water. The compressed tablets consist chiefly or wholly of active substances compressed into form by means of dyes. They are harder and less friable than the triturates and more slowly soluble. (See *Pilulæ*, Part I.)

TABELLÆ CARBONIS ANIMALIS. N. F.

Tablets of Animal Charcoal [Tab. Carb. Anim.]

Replacing Trochisci Carbonis Ligni, *N. F. IV.*; Tablets of Charcoal.

These are compressed tablets each containing 0.3 Gm. (4.6 grains) of animal charcoal.

Dose, one or two tablets.

TABELLÆ HYDRARGYRI CHLORIDI MITIS. N. F.

Tablets of Mild Mercurous Chloride [Tab. Hydrarg. Chlor. Mit.]

Calomel Tablets.

These are compressed tablets each of which contains ⅒ grain (0.0065 Gm.) of calomel colored pink with carmine.

Dose, ten to thirty tablets, usually in divided doses.

TABELLÆ PHENOLPHTHALEINI. N. F.

Tablets of Phenolphthalein [Tab. Phenolphthal.]

Replacing Trochisci Phenolphthaleini, *N. F. IV.*

Each of these contains about 1 grain (0.06 Gm.) of phenolphthalein. They are flavored with cinnamon and cocoa.

The *dose* is one or two tablets.

TABELLÆ SANTONINI. N. F.

Tablets of Santonin [Tab. Santonin.]

Replacing Trochisci Santonini, *N. F. IV.*

Each of these compressed tablets contains about ½ grain (0.03 Gm.) of santonin, flavored with vanilla and cocoa. "Caution: Because of the pleasant flavor of these tablets and the possibility of their being mistaken for candy, it is advisable to order only a very few at a time, preferably not more than three, since 0.13 Gm. of santonin has caused the death of a child." *N. F.*

The *dose* is from one to four tablets for an adult.

TABELLÆ SANTONINI COMPOSITÆ. N. F.

Compound Tablets of Santonin [Tab. Santonin. Co.]

Replacing Trochisci Santonini Compositi, *N. F. IV.*

Each of these contains about ½ grain each of santonin and calomel, flavored with vanilla and cocoa. The same caution applies as in the case of santonin tablets.

The *dose* for an adult is one to four tablets.

TABELLÆ SODII BICARBONATIS. N. F.

Tablets of Sodium Bicarbonate [Tab. Sod. Bicarb.]

Replacing Trochisci Sodii Bicarbonatis, *N. F. IV.*; Soda Mint Tablets.

Each of these compressed tablets contains about 4 grains (0.25 Gm.) of sodium bicarbonate with 1–20th of a minim (0.003 cc.) of oil of peppermint.

The *dose* is from one to four tablets or more, as required.

TABELLÆ SULPHURIS ET POTASSII BITARTRATIS. N. F.

Tablets of Sulphur and Potassium Bitartrate [Tab. Sulph. et Pot. Bitart.]

Replacing Trochisci Sulphuris et Potassii Bitartratis, *N. F. IV.*

Each tablet contains about 3 grains (0.2 Gm.) of washed sulphur and 1 grain (0.06 Gm.) of potassium bitartrate, flavored with oil of orange.

The *dose* is from five to ten tablets.

TINCTURÆ. N. F.

Tinctures

The tinctures of the N. F., like those of the U. S. P., are made by one of two processes. Those of potent drugs are of 10 per cent. strength, corresponding to the International Protocol; the others are of various concentrations.

TINCTURA ALOES. N. F.

Tincture of Aloe [Tr. Aloe.]

This is the same as the tincture of aloe of the U. S. IX. It represents 10 per cent. of aloe.

The *dose* is from one-half to one fluidrachm (2–4 cc.).

TINCTURA ALOES ET MYRRHÆ. N. F.

Tincture of Aloes and Myrrh [Tr. Aloe et Myrrh.]

This tincture is made with 10 per cent. each of aloes, myrrh, and licorice in a menstruum of three volumes of alcohol with one of water.

The *dose* is from one-half to one fluidrachm (2–4 cc.).

TINCTURA AMARA. N. F.

Bitter Tincture [Tr. Amar.]

Stomachic Tincture; Bitter Stomachic Drops; Stomach Drops.

It is made from gentian, centaury, bitter orange peel and zedoary, two volumes of alcohol, and one volume of water, being used as the menstruum. It is a bitter tonic.

The *dose* is thirty minims (2 cc.).

TINCTURA ANTIMONII. N. F.

Tincture of Antimony [Tr. Antimon.]

Replacing Vinum Antimonii, N. F. IV.

This contains 0.4 per cent. of the antimony and potassium tartrate in a menstruum of water and alcohol, colored with caramel and flavored with acetic ether. "Tincture of antimony may be dispensed, when Vinum Antimonii (Wine of Antimony) is ordered." *N. F.*

Dose, from ten to thirty minims (0.6–2 cc.).

TINCTURA ANTIPERIODICA. N. F.

Antiperiodic Tincture [Tr. Antiperiod. Warburg's Tincture]

This tincture is made from rhubarb, angelica fruit, elecampane, saffron, fennel, gentian, zedoary, cubeb, myrrh, camphor, white agaric, black pepper, cinnamon, ginger, quinine bisulphate, and extract of aloes, three volumes of alcohol, and two volumes of water, being used as the menstruum. About 9 grains of quinine bisulphate are contained in 1 fluidounce of finished tincture.

Dosage.—The dosage of Warburg's tincture depends on the kind used—whether with aloes or without—and the intended purpose, and varies from one fluidrachm (4 cc.) to four fluidrachms (16 cc.). The larger quantity is given when Doctor Warburg's original directions are followed for administering the remedy in remittent fevers, which were as follows: "One-half ounce to be given alone without dilution, after the bowels have been evacuated by any convenient purgative, all drink being withheld. After three hours, another half ounce is to be given." It is an antiperiodic.

TINCTURA ANTIPERIODICA SINE ALOE. N. F.

Antiperiodic Tincture without Aloes [Tr. Antiperiod. s. Aloe. Warburg's Tincture without Aloes]

This is made as directed under *Tinctura Antiperiodica,* omitting the extract of aloes.

For dosage, see *Tinctura Antiperiodica.*

TINCTURA ARNICÆ. N. F.

Tincture of Arnica [Tr. Arnic.]

This represents 20 per cent. of arnica in a menstruum of diluted alcohol. It is used chiefly externally.

Dose, from ten to twenty minims (0.6–1.2 cc.).

TINCTURA AROMATICA. N. F.

Aromatic Tincture [Tr. Arom.]

This tincture is made from cinnamon, ginger, galangal, clove and cardamom, two volumes of alcohol, and one volume of water being used as the menstruum. It is used as a carminative and aromatic.

The *dose* is thirty minims (2 cc.).

TINCTURA BRYONIÆ. N. F.

Tincture of Bryonia [Tr. Bryon.]

This tincture is made by maceration and subsequent percolation, using 10 per cent. bryonia and alcohol. It is used as an alterative and hydragogue cathartic.

The *dose* is one fluidrachm (4 cc.).

TINCTURA CACTI GRANDIFLORI. N. F.

Tincture of Cactus Grandiflorus [Tr. Cact. Grand.]

This tincture is made from 50 per cent. cactus grandiflorus and alcohol by maceration and expression and further percolation of this marc. It is supposed by some to act as a regulator of cardiac arrythmias.

The *dose* is fifteen minims (1 cc.).

TINCTURA CALENDULÆ. N. F.

Tincture of Calendula [Tr. Calend.]

This tincture is made by maceration with 20 per cent. calendula and alcohol. Used as an antiseptic and discutient.

TINCTURA CAPSICI ET MYRRHÆ. N. F.

Tincture of Capsicum and Myrrh [Tr. Capsic. et Myrrh. Hot Drops. Thomsonian Number Six]

It is made from capsicum, myrrh, nine volumes of alcohol, and one volume of water being used as the menstruum. It is a powerful gastric stimulant and carminative.

The *dose* is thirty minims (2 cc.).

TINCTURA CIMICIFUGÆ. N. F.

Tincture of Cimicifuga [Tr. Cimicif.]

This tincture is made by maceration and subsequent percolation with alcohol. It contains 20 per cent. of cimicifuga. Used as an alterative and sedative.

The *dose* is one fluidrachm (4 cc.).

TINCTURA CINNAMOMI. N. F.

Tincture of Cinnamon [Tr. Cinnam.]

This is essentially the same as the tincture of the U. S. IX, representing 20 per cent. of cinnamon.

Dose, from one-half to two fluidrachms (2–8 cc.).

TINCTURA COCCULI INDICI. N. F.

Tincture of Cocculus Indicus [Tr. Coccul. Ind.]

This tincture is made from 10 per cent. powdered fishberries with diluted alcohol by maceration and subsequent percolation.

This tincture is used almost exclusively for external application to destroy parasites.

TINCTURA COLCHICI CORMI FORTIOR. N. F.

Stronger Tincture of Colchicum Corm

Replacing Vinum Colchici Cormi, N. F. IV.

This represents 40 per cent. of colchicum corm in a menstruum of one volume of alcohol and two of water. "One hundred cc. of Stronger Tincture of Colchicum Corm yields not less than 0.126 Gm. and not more than 0.154 Gm. of colchicine." *N. F.*

"Note: Stronger Tincture of Colchicum Corm may be dispensed when Vinum Colchici Cormi is ordered."

Dose, from five to ten minims (0.3–0.6 cc.).

TINCTURA CROCI. N. F.

Tincture of Saffron [Tr. Croc.]

This tincture is made from saffron, 10 per cent., in diluted alcohol, prepared by maceration and subsequent percolation. Used as coloring and flavoring agent.

TINCTURA CUBEBÆ. N. F.

Tincture of Cubeb [Tr. Cubeb.]

This tincture is made from cubeb, 20 per cent., in alcohol, by maceration and subsequent percolation. Used as a diuretic and carminative.

The *dose* is one fluidrachm (4 cc.).

TINCTURA DELPHINII. N. F.

Tincture of Larkspur [Tr. Delphin.]

This tincture is made from 10 per cent. larkspur seed in alcohol, made by maceration and subsequent percolation.

This tincture is rarely used internally, but is commonly employed externally to destroy body vermin.

TINCTURA FERRI CHLORIDI ÆTHEREA. N. F.

Ethereal Tincture of Ferric Chloride [Tr. Ferr. Chlor. Æth.]

Bestuscheff's Tincture. Lamotte's Drops.

It is made from solution of ferric chloride, ether, and alcohol. Used as a chalybeate.

The *dose* is thirty minims (2 cc.).

TINCTURA FERRI CITRO-CHLORIDI. N. F.

Tincture of Ferric Citro-Chloride [Tr. Ferr. Citro-Chlor.]

Tasteless Tincture of Ferric Chloride. Tasteless Tincture of Iron.

This tincture contains 35 per cent. of solution of ferric chloride with sodium citrate, alcohol and water. Used as a chalybeate.

The *dose* is eight minims (0.5 cc.).

TINCTURA FERRI POMATA. N. F.

Tincture of Ferrated Extract of Apples [Tr. Ferr. Pomat.]

Tinctura Ferri Malatis Crudi. Tincture of Crude Malate of Iron.

This tincture is made from ferrated extract of apples, alcohol, and cinnamon water. Used as a chalybeate.

The *dose* is one fluidrachm (4 cc.).

TINCTURA GALLÆ. N. F.

Tincture of Nutgall [Tr. Gall.]

This tincture is made from nutgall, 20 per cent., and glycerin, 10 volumes, in alcohol. Made by maceration, instead of the percolation of the U. S. P. VIII. The menstruum was not changed. Used as an astringent.

The *dose* is one fluidrachm (4 cc.).

TINCTURA GUAIACI. N. F.

Tincture of Guaiac [Tr. Guaiac]

This, like the tincture of the U. S. IX, represents 20 per cent. of guaiac in alcoholic menstruum.

Dose, one fluidrachm (4 cc.).

TINCTURA GUAIACI AMMONIATA. N. F.

Ammoniated Tincture of Guaiac [Tr. Guaiac Ammon.]

This is similar to the tincture of the U. S. IX and represents 20 per cent. of guaiac in a menstruum of aromatic spirit of ammonia.

Dose, from one to two fluidrachms (2–4 cc.).

TINCTURA GUAIACI COMPOSITA. N. F.

Compound Tincture of Guaiac [Tr. Guaiac. Co.]

Dewee's Tincture of Guaiac.

This tincture is made from guaiac, potassium carbonate and pimenta, in a menstruum of diluted alcohol. Used for rheumatism, and as an emmenagogue.

The *dose* is one fluidrachm (4 cc.).

TINCTURA HUMULI. N. F.

Tincture of Hops [Tr. Humul.]

This tincture is made from hops, 20 per cent., in diluted alcohol. Made by maceration and subsequent percolation. Used as a sedative and bitter tonic.

The *dose* is one fluidrachm (4 cc.).

TINCTURA HYDRASTIS. N. F.

Tincture of Hydrastis [Tr. Hydrast.]

Tincture of Golden Seal.

This, like the tincture of the U. S. IX, represents 20 per cent. of hydrastis. "One hundred cc. of Tincture of Hydrastis yields not less than 0.36 Gm. and not more than 0.44 Gm. of the ether-soluble alkaloids of hydrastis." *N. F.*

Dose, from one to two fluidrachms (4–8 cc.).

TINCTURA IGNATIÆ. N. F.

Tincture of Ignatia [Tr. Ignat.]

This tincture is made from ignatia, 10 per cent., alcohol, eight volumes, and water, one volume. An assay is provided in the text which states that 100 cc. of the tincture should yield not less than 0.18 Gm. nor more than 0.22 Gm. of alkaloids of ignatia. Its uses are similar to those of Tincture of Nux Vomica.

The *dose* is ten minims (0.6 cc.).

TINCTURA IODIDORUM. N. F.

Tincture of Iodides [Tr. Iodidor.]

Replacing Tinctura Iodi Decolorata; Decolorized Tincture of Iodine.

Although this replaces the former decolorized tincture of iodine the formula differs importantly in that potassium iodide is used in the place of sodium thiosulphate. It is practically a solution of potassium and ammonium iodides in dilute alcohol. It is used externally but is of little value.

TINCTURA IODI FORTIOR. N. F.

Stronger Tincture of Iodine [Tr. Iod. Fort.]

Tincture Iodi Churchill; Churchill's Tincture of Iodine.

This tincture contains 16.5 Gm. of iodine and 3.3 Gm. of potassium iodide in each 100 cc. The solvent is about 70 per cent. alcohol.

TINCTURA IPECACUANHÆ. N. F.

Tincture of Ipecac [Tr. Ipecac.]

Replacing Vinum Ipecacuanhæ, N. F. IV.

"One hundred cc. of Tincture of Ipecac yields not less than 0.135 Gm. and not more than 0.165 Gm. of the ether-soluble alkaloids of Ipecac." *N. F.* It is made by diluting the fluidextract, and represents 10 per cent.

"Tincture of Ipecac may be dispensed when Vinum Ipecacuanhæ (Wine of Ipecac) is ordered." *N. F.*

Dose, from ten to twenty minims (0.6–1.2 cc.).

TINCTURA IPECACUANHÆ ET OPII. N. F.

Tincture of Ipecac and Opium [Tr. Ipecac. et Opii]

Tincture of Dover's Powder.

This tincture is made from tincture of deodorized opium, fluidextract of ipecac, and diluted alcohol, representing 10 per cent. each of deodorized opium and ipecac.

The *dose* is from five to ten minims (0.3–0.6 cc.).

TINCTURA JALAPÆ. N. F.

Tincture of Jalap [Tr. Jalap.]

This tincture is made from 20 per cent. of jalap, with alcohol and water.

The *dose* is one fluidrachm (4 cc.).

TINCTURA JALAPÆ COMPOSITA. N. F.

Compound Tincture of Jalap [Tr. Jalap. Co.]

It is made from 12.5 per cent. of jalap and 3.0 per cent. of scammony, with alcohol and water.

The *dose* is one fluidrachm (4 cc.).

TINCTURA OPII CROCATA. N. F.

Tincture of Opium with Saffron [Tr. Opii Crocat.]

Sydenham's Laudanum; Tinctura Opii Crocata, *P. I.*

This tincture is made from granulated opium, saffron, cinnamon, and clove, by maceration and subsequent percolation with diluted alcohol. An assay is provided. "One hundred cc. of tincture of opium with saffron contains not less than 0.95 Gm. and not more than 1.05 Gm. of anhydrous morphine." *N. F.*

The *dose* is from five to ten minims (0.3–0.6 cc.).

TINCTURA OPII ET GAMBIR COMPOSITA. N. F.

Compound Tincture of Opium and Gambir [Tr. Opii et Gambir Co.]

Tinctura Pectoralis, *N. F. IV;* Guttæ Pectorales; Pectoral Drops; Bateman's Pectoral Drops.

This is made with a menstruum of diluted alcohol. Each fluidrachm represents approximately 2.4 minims of tincture of opium, 3.6 minims of compound tincture of gambir and 0.22 grain of camphor. It is intended for infants.

The *dose* for an infant is from ten to fifteen minims (0.6–1 cc.).

TINCTURA PASSIFLORÆ. N. F.

Tincture of Passion Flower [Tr. Passiflor.]

This is a 20 per cent. tincture of passion flower made with diluted alcohol.

The *dose* is from ten to thirty minims (0.6–1.2 cc.).

TINCTURA PERSIONIS. N. F.

Tincture of Cudbear [Tr. Persion.]

This tincture is made from cudbear (10 per cent.), with a menstruum of three volumes of alcohol and one of water. Used as a bright red coloring agent.

TINCTURA PERSIONIS COMPOSITA. N. F.

Compound Tincture of Cudbear [Tr. Persion. Co.]

This tincture is made from cudbear (1.5 per cent.), and caramel (10 per cent.), with a mixture of one volume of alcohol and two of water as the menstruum. Used as a brownish-red coloring agent.

TINCTURA PULSATILLÆ. N. F.

Tincture of Pulsatilla [Tr. Pulsatil.]

This tincture is made from 10 per cent. pulsatilla, using as a menstruum three volumes of alcohol, and one volume of water.

The *dose* is thirty minims (2 cc.).

TINCTURA QUASSIÆ. N. F.

Tincture of Quassia [Tr. Quass.]

This is the same as the tincture of quassia U. S. IX. It represents 20 per cent. of quassia.

The *dose* is from one-half to one fluidrachm (2–4 cc.).

TINCTURA QUILLAJÆ. N. F.

Tincture of Quillaja [Tr. Quillaj.]

This tincture is made from 20 per cent. of quillaja, extracted with boiling water, the liquid concentrated and 35 per cent. of alcohol added. Used chiefly as an emulsifying agent.

TINCTURA RHEI AQUOSA. N. F.

Aqueous Tincture of Rhubarb [Tr. Rhei Aq.]

This tincture is made from 10 per cent. rhubarb, with potassium carbonate, cinnamon water, alcohol, and water.

The *dose* is from one to two fluidrachms (4–8 cc.).

TINCTURA RHEI DULCIS. N. F.

Sweet Tincture of Rhubarb [Tr. Rhei Dulc.]

This tincture contains 10 per cent. rhubarb, flavored with licorice, anise, cardamom seed and glycerin, in a hydroalcoholic menstruum. Used as a laxative and carminative.

The *dose* is from one to two fluidrachms (4–8 cc.).

TINCTURA RHEI ET GENTIANÆ. N. F.

Tincture of Rhubarb and Gentian [Tr. Rhei et Gent.]

This tincture is made with a menstruum of diluted alcohol. Each fluidrachm represents about 4 grains of rhubarb and 1 grain of gentian.

The *dose* is from one to two fluidrachms (4–8 cc.).

TINCTURA SABAL ET SANTALI. N. F.

Tincture of Saw Palmetto and Santal [Tr. Sabal. et Santal.]

This tincture is made with a menstruum of four volumes of alcohol and one of water. Each fluidrachm represents 12 grains of sabal and 3.75 grains of sandal wood.

The *dose* is one fluidrachm (4 cc.).

TINCTURA SANGUINARIÆ. N. F.

Tincture of Sanguinaria [Tr. Sanguin.]

This is made in a similar manner to the tincture of sanguinaria U. S. IX. It represents 10 per cent. of bloodroot.

The *dose* is from fifteen to forty-five minims (1–3 cc.).

TINCTURA SERPENTARIÆ. N. F.

Tincture of Serpentaria [Tr. Serpent.]

This tincture is made from 20 per cent. serpentaria and two volumes of alcohol and one volume of water as the menstruum.

The *dose* is from one to two fluidrachms (4–8 cc.).

TINCTURA SUMBUL. N. F.

Tincture of Sumbul [Tr. Sumbul]

This tincture is made from 10 per cent. sumbul with two volumes of alcohol and one volume of water.

The *dose* is from one to three fluidrachms (4–11 cc.).

TINCTURA VANILLÆ. N. F.

Tincture of Vanilla [Tr. Vanill.]

This tincture is made by first extracting the drug with alcohol, then drying and grinding the residue with sucrose and percolating this with a hydroalcoholic menstruum. It represents about 19 per cent. of vanilla. It is used as a flavoring agent.

TINCTURA VIBURNI OPULI COMPOSITA. N. F.

Compound Tincture of Viburnum [Tr. Viburn. Opul. Co.]

This tincture is made with a menstruum of glycerin, alcohol, and water. It contains in each fluidrachm about 2 grains each of viburnum opulus and dioscorea and $\frac{3}{5}$ grain of scutellaria and is flavored with cinnamon and cloves.

The *dose* is officially given as one fluidrachm (4 cc.) but a fluidounce (30 cc.) would contain less than one-half an average dose of the combined ingredients.

TINCTURÆ ÆTHEREÆ. N. F.

Ethereal Tinctures

In the general formula for ethereal tinctures the quantity of drug is 10 per cent. A menstruum of one volume of ether and two volumes of alcohol is used. Percolate in the usual manner, but with proper precautions to avoid evaporation.

TINCTURÆ MEDICAMENTORUM RECENTIUM. N. F.

Tinctures of Fresh Drugs

In the general formula for tinctures of fresh drugs 50 per cent. of the fresh drug is macerated with alcohol.

TROCHISCI EUCALYPTI GUMMI. N. F.

Troches of Eucalyptus Gum [Troch. Eucalypt. Gum]

Troches of Red Gum; Red Gum Lozenges.

Each of these contains about 1 grain (0.06 Gm.) of eucalyptus gum.

TROCHISCI ULMI. N. F.

Troches of Elm [Troch. Ulmi]

Each troche contains three grains (0.2 Gm.) of elm, flavored with methyl salicylate. Used as a demulcent.

UNGUENTUM BITUMINIS SULPHONATI. N. F.

Ointment of Sulphonated Bitumen [Ung. Bitum. Sulphon.]

Ichthyol Ointment.

This represents 10 per cent. of sulphonated bitumen in petrolatum.

UNGUENTUM CALAMINÆ. N. F.

Calamine Ointment [Ung. Calamin.]

Unguentum Calaminare; Turner's Cerate.

It contains 17 parts of calamine, with 83 parts of ointment. This sedative protective ointment has properties similar to those of the ointment of zinc oxide, over which it has the advantage of being a pinkish color and hence not so conspicuous when applied to the skin.

UNGUENTUM CAMPHORÆ. N. F.

Camphor Ointment [Ung. Camph.]

It contains 22 per cent. of camphor, with white wax and lard.

UNGUENTUM CAPSICI. N. F.

Ointment of Capsicum [Ung. Capsic.]

It represents 5 per cent. of the oleoresin of capsicum in a base of petrolatum and paraffin.

UNGUENTUM FUSCUM. N. F.

Brown Ointment [Ung. Fusc.]

Unguentum Matris; Mother's Salve.

It contains 50 per cent. of camphorated brown plaster, with olive oil and suet, equal parts.

UNGUENTUM HYDRARGYRI CHLORIDI MITIS. N. F.

Ointment of Mild Mercurous Chloride [Ung. Hydrarg. Chlor. Mit.]

Calomel Ointment; Prophylactic Ointment.

This contains 30 Gm. of calomel with 70 Gm. of white petrolatum.

UNGUENTUM HYDRARGYRI NITRATIS. N. F.

Ointment of Mercuric Nitrate [Ung. Hydrarg. Nit.]

Citrine Ointment.

It is made in the same manner as the citrine ointment of the U. S. IX by the interaction between mercury and nitric acid. It differs somewhat from the corresponding British preparation (see Part I.).

UNGUENTUM HYDRARGYRI OXIDI RUBRI. N. F.

Ointment of Red Mercuric Oxide [Ung. Hydrarg. Oxid. Rub.]

This ointment is made with red mercuric oxide, 10 per cent., water, hydrous wool fat and petrolatum.

UNGUENTUM IODI DENIGRESCENS. N. F.

Stainless Iodine Ointment [Ung. Iod. Denig.]

This is made by dissolving iodine in oleic acid and incorporating with a base of petrolatum and paraffin. It represents 5 per cent. of iodine although it may be questioned whether the therapeutic virtues of this are altered by the manipulations.

UNGUENTUM PICIS COMPOSITUM. N. F.

Compound Tar Ointment [Ung. Pic. Co.]

This represents 4 per cent. of oil of tar, 2 per cent. of tincture of benzoin and 3 per cent. of zinc oxide in a base of yellow wax, lard, and cottonseed oil.

UNGUENTUM PLUMBI IODIDI. N. F.

Ointment of Lead Iodide [Ung. Plumb. Iod.]

This ointment is made from lead iodide, 10 per cent., and benzoated lard, 90 per cent.

UNGUENTUM POTASSII IODIDI. N. F.

Ointment of Potassium Iodide [Ung. Pot. Iod.]

This ointment should be freshly made with 10 Gm. potassium iodide, 1 Gm. sodium thiosulphate, 9 Gm. of water, and 80 Gm. benzoinated lard.

UNGUENTUM RESORCINOLIS COMPOSITUM. N. F.

Compound Resorcinol Ointment [Ung. Resorcin. Co.]

It contains 6 per cent. each of resorcinol, zinc oxide, bismuth subnitrate, and rectified oil of birch tar, with petrolatum, anhydrous wool fat, and glycerin.

UNGUENTUM SINAPIS. N. F.

Mustard Ointment [Ung. Sinap.]

Ointment of Oil of Mustard.

It represents 0.2 per cent. of oil of mustard in a base of lard and white wax.

UNGUENTUM STRAMONII. N. F.

Stramonium Ointment [Ung. Stramon.]

This is made in a similar manner to the stramonium ointment of the U. S. IX. It represents 10 per cent. of the extract of stramonium.

UNGUENTUM SULPHURIS ALKALINUM. N. F.

Alkaline Sulphur Ointment [Ung. Sulphur. Alk.]

This ointment is made with 20 Gm. sublimed sulphur, 10 Gm. of potassium carbonate, 5 cc. water, and 65 Gm. benzoinated lard.

UNGUENTUM SULPHURIS COMPOSITUM. N. F.

Compound Sulphur Ointment [Ung. Sulphur. Co.]

Wilkinson's Ointment; Hebra's Itch Ointment.

It contains 10 per cent. of precipitated calcium carbonate, 15 per cent. of sublimed sulphur, 15 per cent. of oil of cade, with soft soap and lard.

UNGUENTUM VERATRINÆ. N. F.

Veratrine Ointment [Ung. Veratrin.]

This ointment is made with veratrine, 4 Gm., expressed oil of almond, 6 Gm., and benzoinated lard, 90 Gm.

UNGUENTUM ZINCI STEARATIS. N. F.

Ointment of Zinc Stearate [Ung. Zinc Stear.]

This ointment is made with zinc stearate, 50 Gm., and white petrolatum, 50 Gm. The U. S. P. VIII directed the incorporation of the melted zinc stearate, while the N. F. IV directs the incorporation of the zinc stearate without heat.
